THE RADICAL CURE OF FEMORAL HERNIA:

A MODIFICATION OF THE AUTHOR'S OPERATION.

By JAMES H. NICOLL,
Professor of Surgery in Anderson's College, Glasgow.

FEMORAL herniæ, as met in practice, fall into one or other of two classes in the matter of operative procedure. The simpler cases, small herniæ without intra-abdominal tension or other complication, are capable of radical cure by the simplest of measures. Such cases have been repeatedly cured by operative procedures undertaken for the relief of strangulation, and in no way intended to serve as the means of radical cure. In these slighter cases any of the simpler forms of operation may be depended on to effect a cure. Mere ablation of the sac or of its lumen by any method is frequently effective. The "purse-string" suture of Cushing, Fortunato (1), Curtis (2), and others, popularised by Coley (3), Kocher's operation, and the more or less similar suture operations of Bassini (4), Franz (5), Fabricius (6), Bottini (7), and others may all be relied on to secure the permanent disappearance of the hernia.

The more severe cases, on the other hand, large herniæ in patients with corpulent abdomen or other unfavourable feature, are apt to tax the principles of the most ingeniously devised methods. The difficulties of radical cure in these cases have been such as to lead surgeons of large experience to propose operative measures sufficiently striking. Thus, the canal is to be plugged by the healing in of glass balls, of wire gauze, or even [Chaput (8)] of transplanted costal cartilage, or closed by operating from within the abdomen after preliminary laparotomy, or by way of the inguinal region [Ruggi (9), Nasi (10), Parlavecchio (11)]. Buonamici (12) closed the canal by making use of the fascia transversalis, and Gordon (13) by displacing the conjoined tendon of the internal oblique and transversalis muscles from the inguinal to the femoral region. Flaps of bone and periosteum have been turned over from the os pubis [Trendelenburg, Kraske (14), and others], while musculo-fascial flaps have been turned up from the pectineus [Watson Cheyne (15), Saltzer (16), Prokupin (17), and others] and from the adductor longus of the thigh [Schwartz (18)].

The following method of operating, described at the meeting of the British Medical Association in Manchester, in August, 1902, I originally adopted for the more severe and unfavourable cases of femoral hernia only, but have come to regard the precision of the closure effected by it as sufficient inducement to extend its practice to all cases. The use of the sac to form a buttress on the abdominal aspect of the ring, and the closure of the canal by restoring its boundaries to their natural relations (and not by the transplantation of neighbouring structures), are ideas familiar in the operative treatment of hernia, and rendered classic by Macewen in his operation for inguinal hernia. This restoration may be accomplished in femoral hernia with a degree of precision and completeness not, I believe, attainable in any other form of hernia, inasmuch as of the four boundaries of the femoral ring or canal, two only—the anterior and the external—are displaced by the descent of the hernia, the posterior (pubic ramus) and the internal (Gimbernat's ligament) being incapable of displacement. By fixing the anterior boundary (Poupart's ligament) to the posterior (the ramus of the os pubis), an absolute closure of the femoral ring to the extent desired is readily attained. There is nothing, therefore, novel in the principles involved in the two parts of the operation. The technique alone demands description, and it is as follows:—

OPERATION.

This consists of two parts:—

(*A*) *Obliteration of the Sac*, also of the peritoneal depression over the abdominal aspect of the ring, and the substitution of a buttress over the internal aspect of the ring:—

1. Expose the sac, and clear it from surrounding tissues (the skin incision may be vertical or transverse).

2. Open the sac longitudinally in its middle line, and clear of contents.

3. Separate it from parts surrounding its neck, including the transversalis and iliac fasciæ, for one inch round the abdominal aspect of the ring.

4. Bisect the sac longitudinally from fundus to neck. (Fig. 1.)

5. Make an aperture in one-half near the neck. (Fig. 1.)

6. Interlock the halves by putting the other through the aperture. (Fig. 2.) In certain cases it lies better if previously twisted one half turn on its longitudinal axis.

7. Reduce the whole sac through the femoral ring into the extraperitoneal space previously cleared for it by detaching its neck from the abdominal aspect of the ring. The sac thus lies bunched up within the abdomen, between the peritoneum and the transversalis and iliac fasciæ over the internal aperture of the femoral canal.

Where the sac is unnecessarily large, part of it may be cut away before reducing it through the canal.

(*B*) *Closure of the Femoral Ring*:—

1. Carry an incision (bone-deep) from the femoral vein along the pubic ramus to the region of the pubic spine. This divides the pubic portion of the fascia lata, the origin of the pectineus, and the periosteum. Its length will depend on the extent to which the femoral vein has been displaced outwards by the presence of the hernia, and will vary from one inch to one inch and a half.

2. Detach the periosteum to a limited extent, and retract it.

3. Drill the bone near its upper edge in two places, half-inch to one inch apart (one drillhole may be made to suffice). Any bone drill or punch may be used. In the illustration (Fig. 3) the simple hand drill, and the tongue depressor used as a protecting spatula, are those I commonly employ.

4. Pass through one of the apertures a loop of stout catgut or other absorbable ligature. (Fig. 3.) This may be passed by threading it in the eye of a curved surgical needle, or by pushing it through, simply doubled on itself. It is, however, more easily passed by threading it in the eye of the bone drill or in the eye of an ordinary surgical probe. For the purpose I employ a special probe in which the eye is small and placed very near the extremity of the handle. (Fig. 4.) The advantage of that shape and position of the eye will be obvious to those familiar with drills for wiring fractures, or to anyone in his first performance of this operation. With such a probe the operation is of the simplest; without it some difficulty may be experienced in passing the sutures through the one aperture and withdrawing them through the other. The probe should be of the ordinary pliable type.

5. Divide the loop of ligature. Thread one end in a large curved surgical needle and pass it as a mattress

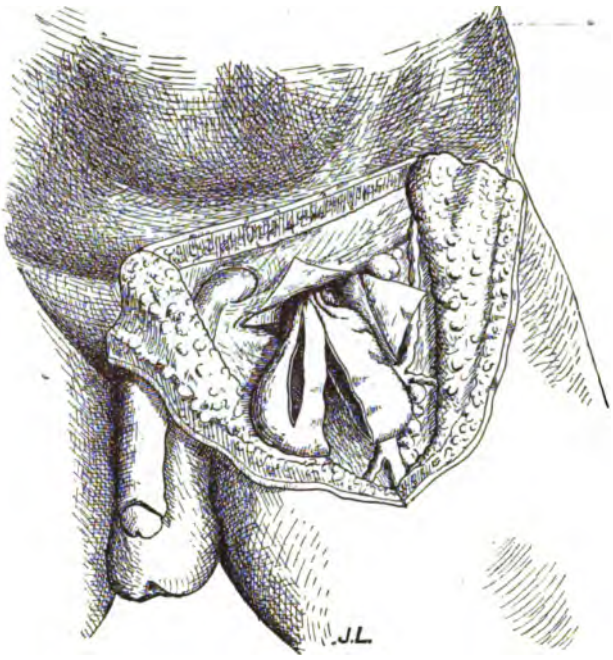

FIG. 1.—Sac emptied, detached from surrounding parts, including internal aspect of abdominal wall, for one inch round femoral ring; split longitudinally, and one-half incised for passage of the other.

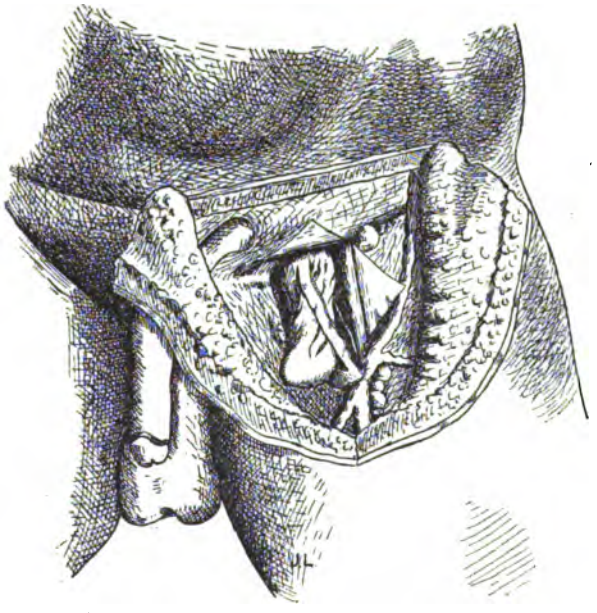

FIG. 2.—Sac ready for reduction, with halves interlocked. (The situation of the aperture in the sac in Figs. 1 and 2, and the relative positions of the two halves of the sac in Fig. 2, are not, in the interests of semidiagrammatic clearness in the drawings, quite those of actual practice.)

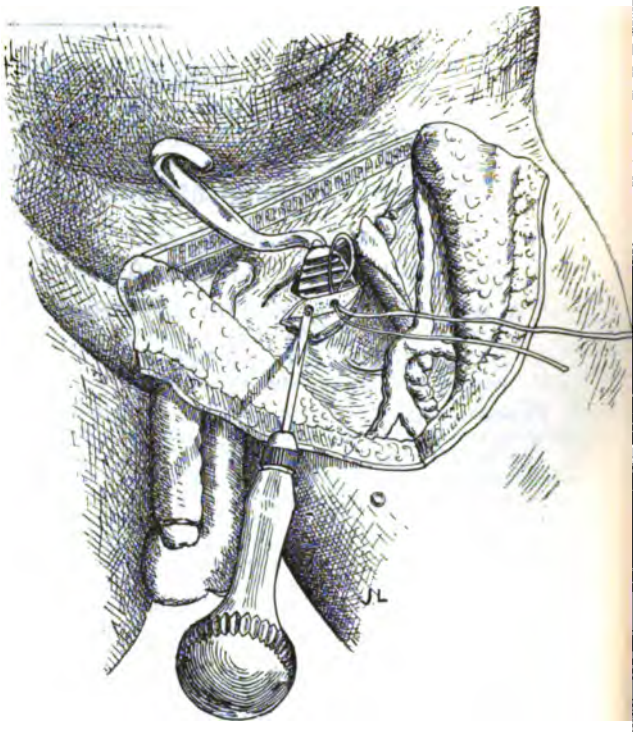

FIG. 3.—Closure of ring; drilling of bone; looped catgut suture passed through first drillhole.

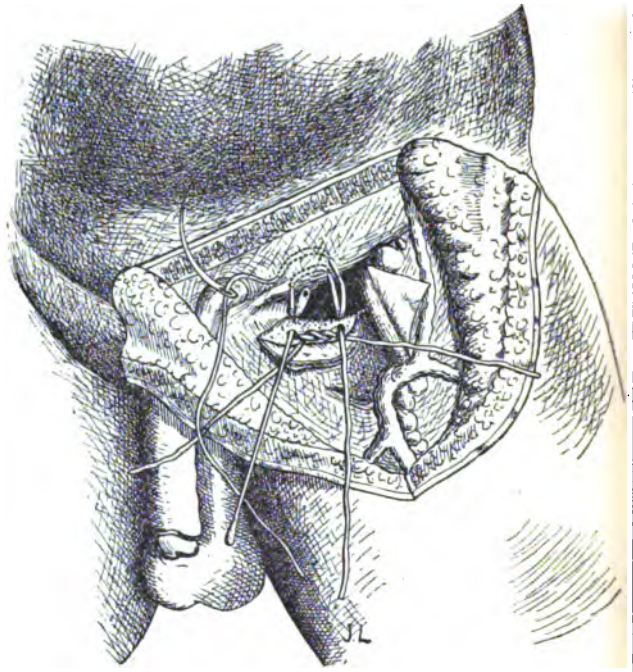

FIG. 4.—Closure of ring; placing of the loops in Poupart's ligament, and return of the ends through second drillhole. (One loop tied loosely to indicate action in pulling Poupart's ligament down to postero-superior aspect of ramus of os pubis.)

suture through Poupart's ligament. Unthread it from the needle. (Fig. 4.)

Repeat this with the second end, carrying it through Poupart's ligament at a higher level (Fig. 4), avoiding the deep epigastric artery to the outer side, and, in male patients, the spermatic cord above. (In very large herniæ the loops, instead of being placed the one directly above the level of the other, as figured, may be made to diverge in the ligament so as to "gather in" the margin of the aperture.)

6. By means of the probe (into the eye of which the ends are threaded), withdraw both ligatures through the second drillhole in the bone. (Fig. 4.) It is in this part of the operation that the special probe is of particular advantage.

7. Tie the ends of each loop separately over the front of the bone, thus bringing Poupart's ligament down to the postero-superior surface of the bone and fixing it firmly in contact with that surface, constituting what

FIG. 5.—Closure of ring; bone sutures tied; completion of closure by suture of fascia lata and pectineus to the fixed Poupart's ligament.

is in effect an extension outwards of Gimbernat's ligament, and absolutely closing the femoral ring to whatever extent may be desired, due regard being paid to the amenity of the femoral vein. The degree of occlusion is regulated by the position of the sutures in Poupart's ligament, but not by the tension with which they are tied. This latter does not vary, the knots being tied in all cases firmly to bring the ligament into contact with the bone. (Figs. 4 and 5.)

8. To make the closure doubly secure, complete the operation by uniting, by interrupted catgut sutures, the detached margin of the pectineal origin, and the pubic portion of the fascia lata to the "anchored" Poupart's ligament. (Fig. 5.)

Remarks.—The operation is easily performed. The first part is simple by comparison with some of the known methods of dealing with the sac, while the second is no more difficult than many of the methods of suture employed in the closure of hernial apertures.

Method of Treating the Sac.—The manœuvre of returning the emptied sac through the canal of a hernia is not new. While descriptions of such operations may be found far back in surgical records, the practice was first put upon a formal footing by Sir William Macewen, and to his advocacy is due the general recognition of the great value of the buttress formed over the abdominal aspect of the ring by the puckered-up sac. Macewen, as is well known, puckers up the sac by a "gathering" suture which, passed through the hernial canal and out through the parietes, is made the means of puckering up the sac on the abdominal aspect of the ring. Variations of the technique by which Macewen's object is attained have been introduced by other surgeons [*vide*, for example, the operations of Davis (19) and Packard (20)], and the method described above is but one of these variations.

The absence of all sutures in the sac has three advantages:—

1. The obvious saving of time.

2. Avoidance of the recognised risk of strangulation, and consequent sloughing, of the puckered-up sac in the grasp of the ligature.

3. The facility with which the entire sac may be placed within the abdomen. A suture emerging from the neck of a large sac may, while pulling the neck within the abdomen, by anchoring it to the parietes, leave the bulky fundus blocked in the canal. The absence of a suture permits the interlocked sac to be pushed as far within the abdomen as may be desired.

Against these advantages there is to be placed, I believe, one disadvantage, and that a minor one, involved in the absence of suture, namely, that the fixing of the sac in position depends on the tying of the sutures closing the ring, and not upon a special sac suture, and that therefore it is necessary, particularly in cases where the patient has "strained" between the placing of the sac and the tying of the ring sutures, to verify and, if need be, adjust the position of the sac before tying the sutures closing the ring. Once tied, these sutures close the ring absolutely, and no prolapse of the sac into the canal is possible. In femoral hernia I have never seen any tendency of the sac to prolapse before closure of the ring, but I have seen it in several cases of inguinal hernia. The explanation may lie in the fact that the inguinal rings are more freely affected by "straining" or deep respiration than is the femoral.

Method of Closure of the Femoral Aperture.—In looking into the literature of the subject, I find that Roux (21) has also been carrying out in the closure of the ring the idea of attaching Poupart's ligament directly to the bone, though employing a different method to attain that end, namely, the use of a ∩-shaped metal nail driven through the ligament into the bone; and it is somewhat surprising that a further search (so far as the regrettable decease of the invaluable *Index Medicus* permits such to be made) should reveal no other references to the utilisation of so conveniently placed a *point d'appui* as is offered by the pubic ramus for the closure of the femoral ring on the classic principle of restoring its boundaries to their correct, or to an over-corrected, position.

The method of closing the ring above described, and which I had been practising for some time before I learned of Roux's independent work, is, in my probably too partial opinion, preferable to that adopted by Roux, for the following reasons:—

1. Roux's operation involves the introduction of a metal foreign body. The subsequent removal of this, if desired, involves a second operation, with the risk of detaching the ligament from the bone in withdrawing the nail. Its permanent retention, on the other hand, involves the chance of the loosening of the nail by absorption (possibly necrosis) of the bone, as occurs not infrequently with wire sutures in fractures. Should this occur, and the nail become dislodged from the bone, by the natural pull of Poupart's ligament or otherwise, a state of matters is established in which every movement of the thigh or abdomen would menace the femoral vessels and the peritoneum with puncture by the points of the nail.

2. The method of suture employed in the operation I have described brings Poupart's ligament down to the postero-superior surface of the bone, attaching it there in the region of the ileo-pectineal line on the plane of Gimbernat's ligament, constituting virtually an artificial extension of that ligament. The effect of such an attachment, as a study of the anatomy of the region will show, is to occlude the femoral aperture at its

extreme upper (inner) end (the plane of Gimbernat's ligament), thus shutting its mouth, instead of closing its throat as the attachment of Poupart's ligament to the superior or antero-superior surface of the bone does.

3. By varying the position of the two mattress loops of ligature, or by making them diverge, in Poupart's ligament, it is easy to effectually close the largest femoral ring without exerting pressure on the femoral vein. The tension of the femoral sheath may be regulated with precision.

4. Roux's nail attaches Poupart's ligament to the periosteum. The operation above described attaches it independently to both bone and periosteum.

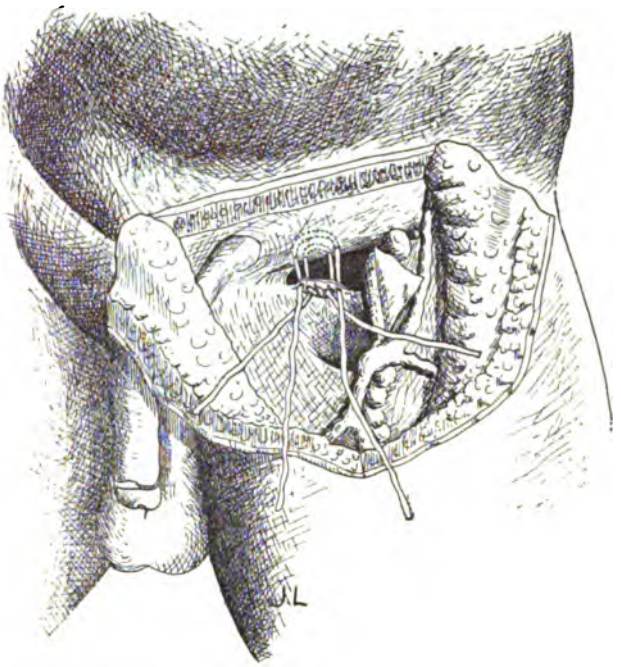

FIG. 6.—Anterior lip of periosteal incision raised in the form of a short periosteo-fascial flap through which the sutures have been passed.

MODIFICATION OF OPERATION.

The following modification is not intended as a regular substitute for the second part of the operation, the closure of the femoral canal. In effect it is less secure. It affords the means, however, of attaching Poupart's ligament in the desired position in cases where the operator is not supplied with a drill, as when hurriedly called to operate in a case of strangulation.

The sac having been reduced into the abdomen, and Poupart's ligament pushed back with a spatula, an incision is carried along the postero-superior aspect of the pubic ramus from the femoral vein to the pubic spine (or part of that distance). This divides the periosteum. Its anterior lip is then raised to a slight extent by any convenient elevator, such as the flat end of an ordinary probe bent to a suitable angle, or the blade of a pair of curved scissors. The effect of this is to form a short periosteo-fascial flap, the size of which has, for the purposes of illustration, been exaggerated in Fig. 6.

With an ordinary curved surgical needle the catgut suture is carried through Poupart's ligament, divided, and the ends, again threaded in the needle, successively passed into the periosteal incision and out again through its anterior lip. (Fig. 6.) The tying of these ends lodges the free margin of Poupart's ligament in the periosteal incision on the postero-superior aspect of the bone, thus closing the canal. (Fig. 7.)

As already mentioned, the closure thus obtained is less secure than that resulting from the bone suture method. Further, if the periosteal incision be made too long, or the anterior lip be raised as far as it necessarily has been in the illustrations, the result will be the attachment of Poupart's ligament, not to the postero-superior, but to the superior surface of the bone, a much less efficient attachment.

To the skill and kindness of Dr. John Lindsay, of Glasgow, I am indebted for the sketches forming the illustrations.

Society for the Relief of Widows and Orphans of Medical Men.

DURING the past year twelve new members were elected, three died, and three resigned, the number of members being 298. Two widows and six orphans applied for relief, three widows died, and one orphan became ineligible. At the end of the year fifty-three widows and fifteen orphans were in receipt of half-yearly grants. A sum of £3,299 10s. was distributed during the year, and the expenses were £246. At Christmas a present was made to the widows and orphans amounting to £583.

A PLEA FOR THE MORE THOROUGH STUDY OF THERAPEUTICS. (a)

By DENNIS VINRACE, M.R.C.S., L.S.A.

As I do not wish it to be thought that, in endeavouring to emphasise the importance of a thorough study of therapeutics as an element in the medical curriculum, I am trying to force an already open door, I should like in the first instance to say a few words as to the present attitude of the public towards medical matters. It is generally supposed that we are living in a highly scientific and somewhat sceptical age, and that nowadays people are apt to subject everything to the touchstone of reason, and are no longer willing to take anything on trust. Broadly speaking, this view is doubtless largely correct, but, curiously enough, in the sphere of medicine this "dry light" of reason, to use Bacon's famous expression, is less generally applied. The day of wireless telegraphy, of Röntgen rays, and numberless other scientific marvels is also a period in which the crudest advertisements of worthless nostrums will open the popular purse-strings to an extent which probably has never been equalled. Of course, medical quackery is no new thing. It would almost seem, indeed, that there is some mysterious instinct which induces otherwise sensible persons to reject what is capable of proof in favour of what is marvellous and beyond the reach of reason, so that, to-day perhaps more than ever, the tried and reasoned formulæ of the Pharmacopœia are passed by; the mysterious concoctions of the quack drug-vendor are accepted with a childlike faith which would be amusing if it was not also pathetic. At the present time it is impossible to take up any popular newspaper or magazine without being faced by pages of quack remedy advertisements, which seem to grow in audacity from day to day. It is clear, then, that, *pari passu* with the great advances which have been made of late in the regions of legitimate medicine, there has been an even greater tendency on the part of the public to have resort to the charlatanry of the compounder of quack drugs.

What is the explanation of this paradoxical state of affairs? The natural tendency of the popular mind to run after new and strange things will not fully account for it, for it is improbable that the present generation is more credulous than its predecessors. No, the explanation must be sought elsewhere, and I would ask whether the success of the quack and the growing habit of self-treatment and consulting the chemist or the herbalist may not to some extent be the fault of the medical profession itself. Is it not possible that there is some defect in the present system of medical training which accounts for this willingness on the part of the public to trust their health and their lives to unqualified persons? In my opinion, the solution of this problem is to be found, to some extent at any rate, in the rather subordinate position which has been accorded to the study of practical therapeutics in the training of medical men. Anatomy, physiology, and pathology have claimed so much attention that there has been a tendency to give therapeutics somewhat less than the attention which it deserves.

To the average general practitioner a profound acquaintance with anatomy or a deep knowledge of bacteriology is, I submit, far less really essential than a sound working familiarity with therapeutics. Of what avail is it that he can locate all the component parts of the human organism, down to the minutest detail, or that he can determine the character of a malady with pathological accuracy, if he has not at his fingers' ends the remedial measures which each particular condition demands, and if he is not personally able to dispense the necessary drugs, or at any rate possesses a sound knowledge of the nature and the combinations into which they can most advantageously be formed? It is as if a man should go into battle with a gun of admirable workmanship, but lack the knowledge to arrange the ammunition which alone could make it an effective weapon.

Very briefly I will deal with two phases of this question—the training received by medical students, and the attitude towards practical therapeutics adopted by the average qualified man. I have recently looked into the examination papers set by the principal qualifying bodies, and I must admit that I found that more attention appeared to be paid to the practical side of therapeutics than in the period when I was myself a student. On the whole, however, it was obvious that to pass their examinations students must still spend by far the greater part of their time on anatomy, physiology, pathology, &c., therapeutics being comparatively unimportant. The natural consequence is that practical therapeutics, being of little help in the securing of degrees, is apt to be rather neglected. Now, I contend that throughout the student's career the value of a thorough knowledge of therapeutics and pharmacology ought to be kept constantly before him. If it be true that in their student days medical men are not led to attach sufficient importance to therapeutics, one would naturally expect to find them in their after years continuing to somewhat cold-shoulder this branch of their calling. And this, I contend, is in fact the case.

Let me take two points—the tendency to neglect minor ailments, and the decadence of dispensing. In regard to the first, I cannot but think that medical men nowadays are too anxious to fly at high game. A mere sore throat or tooth-ache hardly seems worthy of their serious consideration, and yet it is these little matters which should form one of the most constant and reliable features in the average doctor's practice. The result is that people with minor ailments are more and more getting into the way of consulting the chemist when they have, say, a headache or an attack of indigestion, or of doctoring themselves with the catch-penny remedies advertised by the score in every popular periodical. And this is really the thin end of the wedge. When a person finds that his toothache has vanished under the attentions of Mr. Jones the chemist, or after a dose of So-and-so's "Pain Destroyer," he is apt to argue that, after all, a medical man can often very well be dispensed with. In course of time it is not only for petty maladies that he seeks relief in these ways. Even when he has a more serious affection he applies to his old allies for assistance, and another patient is lost to the qualified man. If medical men devoted, proportionately, as much time and care to the treatment of the smaller ills of life as they would to a case exhibiting interesting or unusual features, there can be little doubt that, by reason

(a) Read before the Therapeutical Society, December 22nd, 1903.

of their superior skill and knowledge, they could very largely overcome the competition of the chemist and the drug-vendor. It is worthy of note in this connection that considerable classes of persons, such as chemists, manicurists, chiropodists, and barbers who profess to cure ailments of the hair and scalp, derive a large part of their livelihood from treating the kind of minor maladies which doctors too largely despise.

Turning now to the question of dispensing, I feel convinced that it is very unfortunate that the custom of medical men acting as their own dispensers is going rapidly out of fashion. My ideas may be old-fashioned, but I am satisfied that the old system has several commendable features. By dispensing, a medical man acquires a mastery over the qualities and properties of drugs which no amount of theoretical study can ever give him. He is further able to ensure that his prescriptions are accurately prepared and compounded of good materials, and he is thus in a better position to secure satisfactory results, and is consequently strengthened against the rivalry of the chemist and the quack. But it is not only actual dispensing which is going out of use among medical men. Even the art of writing prescriptions seems to be on the wane. More and more, medical men seem to be coming to depend upon the wholesale druggists. At the present moment the large wholesale firms prepare medicaments after formulæ of their own in absolutely bewildering number and variety, and, as supply is governed by demand, one is forced to conclude that doctors must be very largely availing themselves of this easy and simple means of providing medicine for their patients with the least possible trouble to themselves. No doubt, many of these preparations are excellently adapted to their purpose, but I cannot think that this dependence of medical men on compounds in the preparation of which they have had no part, and of the composition of which they have little or no accurate knowledge, is a healthy sign of the times. If the present tendency continues to increase, it looks as if a time will come when medical men, as far as the giving of remedies is concerned, will be little more than agents for the great drug firms. Why, I may ask, should a doctor abdicate one of his most important functions in this remarkable way? Surely if he has a thorough knowledge of practical therapeutics and pharmacology he should be able to dispense, or at least prescribe, preparations quite as efficacious as any of those which are sold by the wholesale chemists. In so doing, apart from the financial saving, he would have full control over the nature of the medicaments supplied to his patients and a greater power of varying them to meet individual requirements.

There is another point in this connection to which I should like to draw attention. Most of the reputable wholesale houses supplying the profession make a point of stating that their specialities are not supplied to other than medical men, and no doubt this statement is quite honestly made. I think, however, that most of those whom I am addressing will have encountered instances in which these preparations have passed through the hands of retail chemists direct into the possession of members of the public. Some of these specialities also are even advertised in the lay Press, and others make it clear from their format and the elaborate instructions by which they are accompanied that they are intended to be purchased without the intervention of a doctor. The proprietors of some of these nostrums go so far as to state in plain terms that a medical man need not be consulted, so that I think it will be agreed that there is already an appreciable general circulation of drugs which should properly only be administered through the medium of a professional man.

Now, if this is the case already, what may be expected to take place in the not distant future? If the laity is given reason to believe that the remedies which they obtain from their doctors are largely procured ready-made from the manufacturers, they may begin to ask why they should not be able to procure them for themselves without the preliminary need for a medical fee, and it is possible that many wholesale firms may find it worth their while to put their goods openly on the market, even at the risk of losing part of their professional connection. Surely this is a consideration which might make medical men pause before further encouraging the wholesale chemists in the production of preparations according to formulæ of their own.

Upon all these grounds I wish to urge that the claims of practical therapeutics should be paid more attention than they have received in the past. If I might be allowed to make a few concrete suggestions, they would be :—

That each medical student should dispense at the hospital for an hour a day for at least three months.

That the use of stock mixtures and printed formulæ at hospitals should be reduced to a minimum.

That there should be Professors of both practical pharmacy and therapeutics, the former to concern himself with the art of compounding drugs in the most efficient, agreeable and convenient manner, while the latter would instruct as to the action of medicine in health and disease, explain the manner in which one drug may aid another, and describe the action of drugs, both physiologically and therapeutically.

In conclusion, I may perhaps be excused for saying that I feel I owe much to the fact that, when I was Resident Medical Officer at the Golden Square Throat Hospital, the paramount importance of therapeutics was indelibly impressed on my mind by the teaching and example of my distinguished friend Dr. Prosser James. On the clearer realisation of the principles I advocate by the profession at large, I believe that the future prosperity and utility of its members must largely depend.

Paris Clinical Lecture.

ON

SPONDYLITIS OF INFECTIVE ORIGIN.

By DR. L. CHEINISSE,
Ancien-Interne des Hopitaux de Montpellier.

[FROM OUR PARIS CORRESPONDENT.]

VAGUELY recognised towards the middle of the nineteenth century by Chassaignac, who described acute osteomyelitis under the vivid term of "typhus of the limbs," the infective origin of the inflammatory diseases of the bones has since been amply demonstrated by bacteriological research. It is thanks to bacteriology, indeed, that we are

enabled, in addition to the acute osteo-myelitis of children, due to ordinary pyogenic organisms, to recognise other forms of osteo-myelitis which result from the most varied infections, localised in a particular part of the osseous system.

Among these osteo-myelitic lesions those associated with typhoid fever have specially attracted the attention of observers. Nevertheless, although the lesions affecting the tibiæ and ribs, the seats of predilection of typhoidal myelitis, have been known for many years, the same cannot be said of the vertebral localisations of typhoid fever, which, until quite recently, hardly found mention in the numerous works in French and German devoted to the study of the osseous complications of typhoid fever. Out of 144 cases of the kind comprised in Dr. Klein's Thesis (Kiel, 1896), in only one is reference made to the localisation of the infective process in the vertebræ. This case, which was in the service of Dr. Quincke, together with one other similar case, enabled him to describe in 1899, under the name of *spondylitis typhosa*, a group of symptoms which make their appearance either after recovery from the attack of typhoid fever, or during the period of decline. The affection is characterised by intense pain situated in the lumbar vertebræ, with fever, swelling of the affected area, sensory and motor troubles in the lower limbs, and sometimes also of the bladder and rectum.

Since the publication of Quincke's monograph other cases of the kind have been reported, the total number amounting to seven observed in Germany. Quincke mentions that similar cases had been noted in the United States, Gibney regarding the disease as of the nature of a peri-spondylitis, and Osler as a neurosis. These cases appear, indeed, to be tolerably frequent in America, whence the name "typhoid spine." Had the Kiel professor taken the trouble to look up the foreign literature of the subject, he would have found that cases of the kind had already been described by Pallard and others in France. In order to throw light upon the history of this interesting affection I have gone into the subject very thoroughly.

The question arises whether typhoid fever is the only disease which is liable to localise itself in the vertebral column. In other words, does there exist, side by side with typhoid spondylitis, and apart from ordinary spondylitis of the tuberculous and syphilitic varieties, other forms of infective spondylitis? Certain anatomo-bacteriological observations appear to suggest a reply in the affirmative. Fränkel's researches on bone marrow in infectious diseases are specially interesting from this point of view. He discovered Eberth's bacillus in the marrow of the vertebræ of patients who had succumbed to typhoid fever in every instance. Nay more, in the case of a girl who, in the course of an attack of enteric fever, and but a few days before death, developed pneumonia, Fränkel was able to demonstrate the presence in the spinal marrow of the diplococcus alongside of Eberth's bacillus. This discovery induced him to extend his researches to other maladies than typhoid fever. In the course of these further investigations, he revealed the presence of the diplococcus in the marrow of persons who had died of pneumonia, of the streptococcus in cases of erysipelas, pulmonary abscess and diphtheria, and of the Staphylococcus pyogenes aureus in cases of phlegmon and various forms of suppuration.

The presence of these organisms in the marrow of the vertebræ gives rise to a whole series of pathological changes, *e.g.*, hæmorrhages, fibrinous exudations, localised necrosis and the like. Anatomically the bone marrow of the vertebræ shows itself to be as liable to the influence of infective agents, whether general or local, as the spleen. The analogy is the more complete, seeing that the splenic localisation of the infective process, like the vertebral manifestations, exhibits a like tendency to spontaneous resolution, and, in contrast to affections of the long bones, only exceptionally culminates in suppuration, the difference being no doubt due to the comparatively greater vascularity of the marrow and the spleen.

However this may be, it is obvious that although the centres of disease in the depths of the vertebral marrow are, as a rule, so small as to subside without giving rise to symptoms accessible to clinical investigation, they may, in rare cases, determine more or less grave symptoms. In such cases we have infective spondylitis properly so called. Typhoid spondylitis is unquestionably one of the most typical forms, but other varieties have been observed.

Quite recently Quincke published two very characteristic examples thereof. Case I was that of a man, æt. 46, who, about six weeks after the onset of an attack of pneumonia of average severity and running the usual course, suddenly complained of acute pain in the lumbar region of the spinal column, not accompanied by any rise of temperature. Admitted to hospital, he remained an inmate for upwards of five months, on account of well-marked spondylitis, which left, after recovery, some swelling of the spinous processes of the second and third dorsal vertebræ. The hypothesis of the process being tuberculous could be discarded on account of the absence of any rise of temperature, and of the absence of any pulmonary disease and hereditary antecedents, and, on the other hand, there was no history of traumatism. The author, therefore, arrived at the conclusion that it was a case of pneumococcic spondylitis. In the other case, a farmer, also æt. 46, was admitted to hospital with right-sided empyema, which, ten days previously, had burst into the lungs with expectoration of pus. Several ribs were resected and the pleura opened, whereupon the expectoration of pus considerably diminished, and in about six weeks the patient, who had meanwhile gained twenty-five pounds in weight, was discharged. Some weeks later he began to complain of pain in the lumbar region. The pain was but slight when he was lying down, but became very severe on the slightest movement or on pressure, so that he was readmitted. Investigation revealed the existence of some rigidity of the spinal column, with tenderness on pressure over the lumbar spinal processes, especially over the third lumbar vertebra. In the left lumbar region, just above the iliac crest and about three-quarters of an inch from the spinal processes, a swelling the size of a goose's egg was perceived. An exploratory puncture did not give issue to pus, and the patient was allowed to go home after fitting him with a plaster jacket.

As this patient was suffering at the time from chronic bronchitis, it was, of course, possible that he had Pott's disease, but, judging from the

subsequent history of the case, supplied by his medical man—the symptoms having cleared up in the course of a few months—this hypothesis cannot be substantiated. Dr. Quincke therefore concluded that the symptoms were the sequel of the empyema, and since the pleural exudation was rich in streptococci, he inclined to the view that the vertebral affection was of streptococcic origin.

It is obvious that the two cases just briefly related present considerable analogy with cases of typhoid spondylitis. The severity of the pain, the swelling of the soft parts, and the more or less persistent rigidity of the affected segment of the spinal column seem to point to implication of the periosteum and ligaments, and to justify the name "perispondylitis" given to it by Gibney. If we add the slight tendency to suppuration and the predilection of the morbid process for the lumbar region, we have a group of symptoms common to all varieties of spondylitis.

It may be conceded that Quincke's cases alone would hardly suffice to establish the existence of infective spondylitis. But apart from the fact that they fit in very well with the bacteriological results obtained by Fränkel, it is only fair to add that other clinical observations tend to confirm this view. In the course of the discussion at the Medical Society of Kiel on one of Quincke's cases, two other cases were mentioned, one following an attack of pneumonia and one after scarlatina.

It would be a mistake to suppose that the Kiel professor was the first to call attention to these vertebral manifestations in association with infective diseases other than typhoid fever. We have only to refer to Gibney's paper on typhoid spine to see that in the discussion to which the paper gave rise Shaffer stated that he had met with similar morbid incidents *not only after typhoid fever, but also after scarlet fever and measles.*

If, in his practical remarks on the subject, Quincke thought it desirable to advise the avoidance during convalescence from infective diseases of all risk of traumatism and over-exertion of the spinal column, the fact remains that fourteen years before, Shaffer made use of almost the same words in discussing the influence of "excessive exercise or a direct blow or fall after an acute fever."

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXVII.

BY OUR SPECIAL MEDICAL COMMISSIONER.]

OVERTON HALL SANATORIUM, BOURNEMOUTH.

OVERTON HALL is a large villa residence so constructed and adapted as to meet in some measure the requirements of a small private sanatorium for consumption. Its situation is by no means ideal, for it is on the north side of the busy Bournemouth tram-route, Poole Road, from which it is only separated by a comparatively small garden. This location, while doubtless convenient in many ways, has many serious drawbacks, for it lacks in quietness and privacy, and in summer months cannot be free from dust. The close proximity of other residences is also a disadvantage.

The institution was first established by Dr. Pott, but is now, as we understand, in the hands of Dr. Stein.

The building has an attractive appearance. It is built of red brick, and forms a hollow square minus the north side. The extensive south front of some 80 ft. provides a series of pleasant rooms for the patients. Short wings diverge from the two corners. Between these projecting ends there is a lofty and wide verandah, which communicates with the lower bedrooms and is provided with glass screens, and has glass windows in its roof for ventilation. This structure seems to be much used by patients as a resting shelter, but we should imagine it is in danger of becoming a kind of all-the-year-round "winter garden." Above the verandah is a partially roofed over balcony. There is a good corridor-hall running the whole length of the house, and affording a common ground where "the patients pass the evening in conversation and reading the daily papers."

Many of the bedrooms are good, although by no means coming up to the hygienic standards set by some recent sanatoria. The rooms, indeed, have too "homely" an aspect. As far as we could see, every care is taken to maintain absolute cleanliness. The furniture, mostly of mahogany, is more elaborate than is usually seen in sanatoria. There are, of course, no fixed carpets, but a plentiful supply of rugs which, considering the site and size of the sanatorium, must be great dust collectors and require considerable labour to keep clean.

The wings of the building contain a number of bedrooms smaller, however, than those on the south side.

Heating is by means of open fires. Lighting is by electricity. The sanitary arrangements appear to be good.

The grounds are very limited, being only about one and a half acre in extent, but they are provided with various "sun traps" and revolving shelters.

Treatment is conducted in accordance with the now generally recognised hygienic principles. The sanatorium is only intended for early cases. For such patients as are suited for Bournemouth, Overton Hall offers many advantages. The public gardens and sea front can be readily reached, and undoubtedly the electric cars offer a ready means of locomotion which, wisely or not, is certainly largely made use of.

For subjects disliking the routine and restraints of institutional life, and desiring the comforts and conveniences of a private house, this establishment has distinct attractions.

There is an excellent resident matron and a good staff of attendants.

The terms are from four to five guineas.

Overton Hall is only a few minutes' walk from West Bournemouth Station, and, as already indicated, the electric cars pass the gates.

THE NATIONAL SANATORIUM FOR CONSUMPTION AND DISEASES OF THE CHEST, BOURNEMOUTH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—So much has been done during the last five years to bring the National Sanatorium structurally up to date that we must take exception to the statement of your Special Commissioner that "it cannot claim to rank high among modern sanatoria." (1) The wards and corridors are very well ventilated, the old windows being replaced by double casements and fanlights, the wards on the ground-floor having, in addition, openings into corridor, as described in your article in one ward only. (2) The whole of the sanitary arrangements have been rebuilt. (3) Electric light has been installed all over the building and shelters. (4) The dining-rooms each have four double casement windows. (5) The partition between the day-room and the corridor has been removed, thus admitting more light and free circulation of air throughout the building.

The grounds are three acres in extent. There is accommodation now for seventy-two patients. Plans for an additional extension have been revised and will provide for ten to twelve new beds. There are now six nurses working under the matron.

Although one cannot expect to alter an existing building so that it will have quite the same appearance as one of the modern sanatoria, yet the alterations carried out here have to a great extent brought the

institution into "accordance with modern principles of sanatorium construction."

I am, Sir, yours truly,

A. GEO. EYRE HARRIS, M.D.Dub.

[We are glad to insert the above statements, which certainly show that no pains have been spared to attain as high a standard as may be possible under existing conditions. Our Commissioner will reply in next issue.—ED.]

Transactions of Societies.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD DECEMBER 11TH.

MR. SYDNEY STEPHENSON, F.R.C.S., in the Chair.

DR. A. MONSON showed an

ABDOMINAL CASE FOR DIAGNOSIS.

The patient was a boy, æt. 9, who had suffered from an attack of nephritis, accompanied by general œdema, albuminuria, and tube casts. After recovery he was sent to a convalescent home, and there a lump was discovered in the left side of the abdomen, situated low down. The boy said he had been conscious of something movable there for six months. Dr. Monson found a mass in the left iliac fossa which was fixed, and a part above which was movable. He believed the movable portion of the tumour was a floating kidney, which might possibly have become twisted so as to develop the renal symptoms above described.

Dr. CAUTLEY thought the lump was more or less fixed, that the attack of nephritis was probably unconnected with it, and that the mass was possibly tuberculous.

Dr. PERCY LEWIS (Folkestone) recalled a similar tumour mass, leading to intestinal obstruction, which proved to be a dermoid cyst.

Dr. GUTHRIE thought there was a movable kidney on the left side, and that the swelling below was probably tuberculous.

Mr. ARNOLD LAWSON showed a case of

EXOPHTHALMIC GOÎTRE

in a girl, æt. 12. The physical signs were all well marked. The chief interest of the case lay in the extreme youth of the patient, very few cases of Graves' disease at such an early age having been recorded. No cause could be assigned for the onset of the disease. The child's health had been excellent previously, and there was no family history of insanity or nervous disease. The constitutional effect of the illness on the child was very slight, although the disease had been in progress for over twelve months.

Dr. ROBERT HUTCHISON referred to a case he had seen in a child of eight years, and asked if there were any affection of the pelvic organs, and if early menstruation had occurred. The association of pelvic disorder in women with Graves' disease was a subject more worthy of study.

Dr. SANSOM referred to the case of a child of twelve who developed this infection after an attack of influenza.

In reply Mr. LAWSON said he had not examined the pelvic organs, but the menses had not commenced. There was no definite neurotic element about the child.

Dr. E. P. BAUMANN showed a boy, æt. 7, suffering from mediastinitis. Last July he suffered from acute rheumatism, complicated by endocarditis and pericarditis. In September puffiness of the face and ascites developed. There was found to be a large liver and an enlarged heart. The abdomen had been tapped several times, but the evacuation of the fluid made no difference in the venous dilatation of the neck. Examination by the X-rays threw no further light on the case. In view of the history and the clinical symptoms, a diagnosis of adhesive mediastinitis had been made. The boy's general health was good.

CASE OF DISPLACEMENT OF THE THYROID.

Dr. GEORGE CARPENTER showed a girl, æt. 16, with a tumour at the root of the tongue, which was accidentally discovered. The mass was probably a dermoid in connection with the thyro-glossal duct. The thyroid gland could not be felt in the neck, and the possibility of the lingual swelling being a misplaced thyroid was suggested.

Mr. JAFFREY thought the swelling occupied the site of the thyro-lingual duct.

Dr. FRANK COLLIE said he had known the patient for four years, and until one and a half years ago there was no question of any swelling. At the latter time she began to menstruate, and two months later a prominence developed in the region of the chin, which might have been due to the effort to get a freer passage of air. Two well-known specialists in throat diseases had seen the case, and agreed that it was probably a case of displacement of the thyroid on to the dorsum of the tongue. As the child suffered no inconvenience, he advised that it should be left alone.

Dr. CARPENTER also showed a case of congenital heart disease, and a case of cirrhosis of the lung.

THE AFTER-EFFECTS OF POLYNEURITIS.

Dr. LEONARD GUTHRIE showed a boy, æt. 12, who seven years previously had suffered from a severe attack of polyneuritis of uncertain origin. At the end of three months he had completely recovered, save that the knee-jerks were absent, and there was a tendency to contraction of the tendo Achillis on both sides. He had been admitted into hospital during the present year suffering from a well-marked condition of talipes equino-varus, for which tenotomy had been performed, with improvement of the walking powers. At present he showed a condition of pes cavus on both sides, strongly resembling that of Friedreich's disease, but without ataxy. The knee-jerks were absent, the muscles of all the extremities were small, but there was no paralysis. He was somewhat deficient mentally. After excluding other possible causes of the condition, such as spastic paraplegia, Dr. Guthrie concluded that the case illustrated the after-effects of polyneuritis.

Dr. JAMES TAYLOR agreed with the diagnosis, and suggested that there had been six years ago some general toxic condition. This had not only affected the peripheral nerves, but also the anterior horns of the cord and the highest cerebral centres. This had caused the impaired mental condition which was now present.

Dr. FLETCHER BEACH thought that there was defective moral control, probably the result of the early illness.

Dr. GUTHRIE also showed a girl, æt. 11, with physical signs which he regarded as those of aortic valvular disease, with stenosis. The maximum of the intensity of the murmur was in the second left intercostal space.

Dr. THEODORE FISHER said that disease of the aortic valves, either congenital or acquired, was not so rare as was usually supposed. A variety of lesions affecting the aortic valves was found on post-mortem examination. Various diagnoses as to the cardiac condition were given by members, including mitral disease, aortic regurgitation with presystolic thrill and murmur (Flint's murmur), pulmonary valvular disease, and patent ductus arteriosus.

Mr. J. W. THOMSON WALKER showed a dermoid cyst which he had removed from the front of the sternum in a girl, æt. 5. Since infancy a small round swelling had been observed, which had increased to the size of a large horse-chestnut. It was easily dissected out. On microscopic examination, hair follicles, sebaceous glands, and sweat glands were easily recognised.

Mr. DOUGLAS DREW showed a specimen of tuberculous caries of the upper dorsal spine, with an abscess pressing on the bifurcation of the trachea. The patient was a child, æt. 5, who, while under treatment for spinal disease, developed some difficulty in breathing, which at times became rather urgent. One of these seizures proved fatal from asphyxia. The upper dorsal vertebræ were found to be extensively diseased, and there was a large thick-walled abscess pressing on the trachea and bronchi.

Dr. GEORGE CARPENTER showed a specimen of a lung removed from an infant, 5 months old. The lower

lobe of the left lung was cystic, the largest cyst being the size of a small orange. It was probably of congenital origin, and akin to the cysts found in the kidneys and spleen. During life the prominent feature was dextrocardia.

Mr. ALBERT CARLESS read a paper on some cases of "Lymphangeiomata," which was discussed by Mr. Douglas Drew and Mr. Thomson Walker.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT MANCHESTER, FRIDAY, DECEMBER 18TH, 1903.

DR. J. E. GEMMELL, President, in the Chair.

CARD SPECIMENS.

MR. STANMORE BISHOP.—A series of specimens of hydro- and pyo-salpinx, a fibroid uterus, proliferating papillomatous cysts of the ovary.

Dr. W. E. FOTHERGILL.—Ectopic gestation, pyonephrosis following movable kidney.

Dr. J. H. WILLETT.—Tubal mole in process of extrusion.

Dr. LLOYD ROBERTS.—Ovarian cyst with twisting of the pedicle.

Dr. W. WALTER.—Fibro-myomata of uterus.

Professor W. J. SINCLAIR (Manchester) showed glass drainage-tubes used in vaginal hysterectomy. He had devised these because he was not satisfied with ordinary rubber ones, which were apt to become choked by fibrous clot. The glass tube resembled a short narrow test tube with a very wide flange, and it was perforated by several rows of holes. It could be washed out with normal saline solution and kept clear of clot.

Dr. ARNOLD LEA (Manchester) said he had had personal experience of the tubes, and they had all the advantages claimed for them.

Dr. J. B. HELLIER (Leeds) related a case of

SEPTATE UTERUS AND VAGINA; LABOUR OBSTRUCTED BY THE VAGINAL SEPTUM.

She had had only one child, and when the medical attendant arrived to conduct the labour, he found both feet contained in a sort of pouch on the left side of the vagina. This pouch appeared to be closed below, and the feet were ultimately extracted from it and delivery completed, the perinæum, however, being lacerated. The latter was sutured, but did not heal, so the patient was sent to Dr. Hellier, who thus obtained the opportunity of examining the conditions under anæsthesia. He found a broad fundus uteri with a depression in its centre; a single os externum, within which was a well-marked septum dividing the cavity of the uterus into two halves of equal length; a well-formed vaginal septum of fleshy consistence, which was deficient above in front of the os. The two halves of the vagina were open above and below. The septum was excised.

Dr. BLAIR BELL (Liverpool) read notes of

AN UNUSUAL CASE OF ECTOPIC GESTATION.

The patient was a single young woman with a long history of "indigestion" and "bilious attacks." For several days she had had repeated attacks of severe abdominal pain, but persisted in going about as usual and in declining to see a doctor, as she attributed this pain to "indigestion." Ultimately Dr. Bell saw her, and found that menstruation had always been profuse, and that a supposed period which had continued for ten days (unusual for her) was just "going off." Rectal examination was negative, but there were rigidity and tenderness of the right iliac fossa. The pulse was slow and the temperature low. It was considered that there was probably appendicular trouble with impending gangrene or perforation, so laparotomy was performed. Much blood was found in the abdominal cavity and the cause of the illness revealed. The right pregnant tube was removed, leaving the ovary intact. The entire length of the vermiform appendix was adherent to the back of the cæcum, so it was freed and removed also. Dr. Bell remarked that had the appendix been normal he would have removed it in any case to prevent any chance of disclosures in the future. The patient recovered perfectly, and has since been free from "bilious attacks."

Dr. J. H. WILLETT (Liverpool) read a pathological report on the specimen removed by Dr. Blair Bell, and showed lantern slides of sections made from it. The remarkable point about it was the extreme and universal thinning the tube had undergone.

The PRESIDENT inquired if there was any acknowledged menstrual irregularity?

Dr. ARNOLD LEA asked whether there had been any indications of attacks of appendicitis in the past. Could the condition be attributed to adhesions round the appendix? Dr. Hellier commented on the advisability of removing a healthy appendix. Professor Sinclair favoured the view that an attack of appendicitis might predispose to tubal disease, and related a case in support of his statement. Dr Garner (Preston) and Dr. Fingland (Liverpool) having spoken, Dr. BELL replied. He said there was no evidence of the spread of inflammation from appendix to tube in this case. The two conditions were quite distinctly independent of one another.

Dr. W. K. WALLS (Manchester) detailed a case of "Severe metrorrhagia in a girl, æt. 14." Ergot proved valueless, so the uterus was curetted, the cervix being so patulous that it was scarcely necessary to use dilators. A very large number of long thick strips were removed. The condition was cured after this had been carried out.

Dr. LLOYD ROBERTS said that in such cases ergot was of little use, iron and purgatives being more beneficial. Local applications of iodine used to cure before curetting became fashionable, but the latter had been the best treatment in this case.

Professor W. J. SINCLAIR said that the pathology in such a case was mere guess-work, although it might perhaps have been possible to ascertain some possible ovarian change. Was the uterus smaller in size a few periods after the curetting, or larger? He suggested the possibility of some sexual element, and mentioned a case in which bleeding had ceased after marriage.

Dr. W. WALTER considered that the cause of the trouble had been in the uterus, as the curetting had cured the bleeding.

Dr. W. E. FOTHERGILL suggested some developmental error as a possible cause. He instanced the irregular profuse menstruation met with just after puberty, and said that Dr. Walls' case might be an exaggeration of an ordinary type of case. At puberty there occurred an increase in blood-vessels and muscular fibres. If the latter were defective or late in appearing hæmorrhage would occur, and ergot would not control it, because there were no muscular fibres for it to act upon. The same cause was in action at the menopause.

Dr. J. J. O'HAGAN (Garston) said that possibly a small fibroid which had escaped detection might have accounted for the bleeding. He had known this to be the case in an older girl.

The President and Dr. Hellier having spoken, Dr. WALLS said, in reply, that hæmophilia and a small fibroid had been excluded, and the sexual element had not been inquired into. The curettings were about an eighth of an inch in thickness, but the microscopical examination did not reveal any increase in the blood-vessels. At the same time he thought that Dr. Fothergill's explanation of why ergot failed in these cases would stand criticism.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DECEMBER 17TH, 1903.

RUSHTON PARKER, Esq., B.S., F.R.C.S., President, in the Chair.

MR. THELWALL THOMAS exhibited receptacles for dressings designed by him to facilitate the carrying out of aseptic surgery in private practice. The boxes

are rectangular, the lid placed underneath, and let in in such a way that when the box rests on a flattened surface dust cannot enter; the sides have perforated "hit and miss" slides. They fit into a large steam steriliser, and each box will hold the necessary dressings, bandages, sheets of sterilisable waterproof material covered with thick muslin, and two specially designed gowns. A dark mackintosh cloth case fits over the box for transportation.

The PRESIDENT said the boxes shown were by far the most convenient and suitable ones he had seen.

Dr. GORDON GULLAN showed a lad, æt. 18, suffering from morbus cæruleus. He was able to follow his trade as a watchmaker. There were signs of enlargement of the right heart, with obstruction of the pulmonary artery, and probably a patent ductus arteriosus.

Dr. Gullan also reported two cases of cretinism in youths, æt. 20, one patient being shown. Both were typical cases. One was improving under thyroid; the other had shown no improvement.

Dr. HUBERT ARMSTRONG referred to the risk of sudden death in congenital heart disease, and mentioned two cases in his own experience, one a baby, and the other a boy of twelve.

Mr. NIMMO WALKER showed a woman, æt. 49, with double optic atrophy and double third nerve paralysis. There was a history of "inflammation of the bowels" two years previously, with vomiting and headache, and the lesions were probably due to a basal syphilitic meningitis, implicating the affected nerves in the interpeduncular space and the chiasma. Mr. Walker said it was a rare case, and had only occurred once in 9,000 patients seen at St. Paul's Eye and Ear Hospital in the present year. Some power was returning under mercurial inunction and potassium iodide internally.

Mr. GEORGE G. HAMILTON read a paper upon

RAPID PARAPLEGIA,

and reported a case, which will be published in full later. In commenting upon the condition he thought discussion might usefully turn upon the following conditions:—Traumatic neurasthenia, meningitis, spinal hæmorrhage, Landry's paralysis, peripheral nerves, and toxic palsies. In this particular case the post-mortem revealed a hæmorrhagic myelitis.

Dr. E. E. GLYNN had examined the spinal cord and cerebro-spinal fluid, and had found no evidence of bacterial infection.

Dr. W. B. WARRINGTON said many cases of so-called acute myelitis were really due to softening of the cord following syphilitic arterial disease, but the differential diagnosis was difficult. He suggested that a syphilitic history, the spread of the symptoms from one limb to the other, with the Brown-Séquard features, might help, and quoted two cases in which this symptom-complex was present. Primary hæmorrhage into the cord was extremely rare. It was important to recognise a syphilitic origin for its guide to treatment.

Drs. T. R. Glynn, Raw, Carter, and Barr spoke, and Mr. HAMILTON replied.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD WEDNESDAY, DECEMBER 9TH, 1903.

Professor HENRY CORBY, M.D., in the Chair.

PROFESSOR CORBY read a paper on

SOME DISEASES OF THE PLACENTA CAUSING ABORTION,

dealing especially with fatty degeneration of the placenta, and the occurrence of apoplectic lobules or cysts, due to effusion of blood in the placental tissue. He showed a typical specimen of this latter condition.

A discussion on the paper followed.

Dr. D. J. O'CONNOR read a paper on

THE QUESTION OF BLOOD-LETTING IN ACUTE PULMONARY DISEASES,

in which he argued that the practice of venesection, though now entirely out of fashion, might be employed with advantage in many cases of this description, and said that some of the best authorities were now in favour of the revival of the practice in certain cardiac and pulmonary diseases.

A discussion took place on this paper also.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 2nd, 1904.

RENAL OPOTHERAPY.

AT the meeting of the Académie de Médecine, M. Tenault read a paper on the treatment of chronic albuminuria by opotherapy, in which he related the cases of three patients suffering from chronic Bright's disease, interstitial nephritis and cardiac albuminuria respectively, who were treated with macerated pork kidneys. The albuminuria disappeared completely, and the quantity of urine excreted became normal.

The administration of the remedy should not exceed ten days, after which it should be suspended for four or five days.

TINEA TONSURANS.

The treatment of this troublesome affection is varied and frequently exhausts all the microbicides known.

Professor Charmeil counsels as general treatment, outdoor exercise, sea air, tonics in the form of glycerophosphates, arsenic, cod-liver oil, &c. As local treatment, depilation of the patches three or four times in the course of the disease. As application, pure acetic acid painted on the part by a pencil made of a piece of cotton wool on a stick, and rubbed gently in followed by drying with a bit of soft cotton. A certain amount of inflammation bordering on vesication is the consequence, but in ten days the part resumes its normal appearance. Other agents may be tried, however, as liquid ammonia, croton oil, tincture of iodine, essence of winter green in ether (1 in 3). Twice a week the whole head is rubbed with:—

Proof spirit, ℥x.
Spirit of lavender, ℥iv.
Bichloride of mercury, grs. xii.
Tincture of cantharides, ℥iv.
Hydrate of chloral, ℥i.

PSORIASIS.

Professor Renault, of Paris, in his local treatment of psoriasis employs but one or other of the three following agents after the squamæ have been removed by baths:—Oil of cade, pyrogallic acid, and chrysophanic acid. The first preparation he mixes with glycerine and starch thus:—Cade oil, ℥i; glycerine, ℥iii; starch, ℥ii; to be rubbed night and morning. If this preparation has the advantage of being sure in its action and non-toxic, it has the inconvenience of provoking a certain amount of irritation and of smelling disagreeably. Pyrogallic acid is odourless, but produces black stains, and cannot be used except in circumscribed patches. The same might be said of chrysophanic acid, which, although very efficacious, presents certain disadvantages; it gives a violet colour to the teguments and yellow to the hair, and produces local erythema and sometimes bilateral conjunctivitis. Bearing all these points in view, preference should be given to oil of cade.

The internal treatment should be essentially arsenical. In some countries great confidence is given to large doses of iodide of potassium, but M. Renault does not see what use it can be in psoriasis.

THE site of twelve acres in South London, presented by the Hon. W. F. D. Smith, for the new buildings of King's College Hospital, has been supplemented by a gift of £1,000 from the firm of Messrs. W. H. Smith and Son, and the promise of a similar amount next year.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 2nd, 1904.

At the Medical Society Hr. Lassar spoke on

INOCULATION EXPERIMENTS ON ANTHROPOID APES WITH SYPHILITIC VIRUS.

He said that twenty years ago he had inoculated animals with syphilis, but his experiments, like those of others, had had negative results. Roux and Metschnikoff had more recently experimented with highly developed apes, and he himself had inoculated a chimpanzee four or five years of age, which had been healthy and lively in confinement. The patient from whom the virus had been taken had been inoculated whilst being tattooed on the arms, and at the time the material was taken had swelling of the glands and an amphora. The inoculation was done on October 22nd, and on several places in the skin. No local reaction took place. After a fortnight, however, infiltrations appeared over both eyebrows; these speedily broke down, and the part took on the appearance of a chancre. These sores showed scarcely any tendency to heal, and were even now almost unchanged. A little higher on the head, about the middle of the forehead, appeared what must be called a papula. Other phenomena appeared at a distance from the inoculation spots. Roundish patches, raised at the edge and depressed in the centre, appeared on the palms of the hands and soles of the feet and around the anus. At the same time the hair got light in patches as in the human subject.

The symptoms were beginning to appear less marked than at first. As such animals did not breed in captivity, the carrying out of such experiments was rendered more difficult. A second ape was inoculated from the first on December 1st, but the animal was already suffering from tubercle of the intestines. At the site of the inoculation a weakened form of infection could at most be determined.

At the Society of Charité Physicians Hr. Kraus, in showing a case of

CARCINOMA OF THE ŒSOPHAGUS,

described the recent methods of diagnosis in disease of the œsophagus and diverticula, and explained the various methods of Röntgen illumination, both in the direct and oblique directions, illumination by means of sounds and the bolus process, and showed illustrative plates. One photograph was of special interest, that of a case of diaphragmatic hernia where the shadow of a sound filled with mercury was seen curving below the diaphragm, and was observed to twist round several times in the stomach.

Hr. Rectezeh showed a case of

GLANDULAR TUBERCULOSIS

with an interesting history. The tumours, which were the size of the adult head and lay over the ribs, were of diagnostic interest. Pseudo-leukæmia, Kundrat's malignant lymphoma, and the tumour-like form of lymph gland tuberculosis were to be considered. The first-named disease could be excluded by the rapid course (development of the tumours in a few months), the condition of the blood (absence of relative lymphocytosis, presence of polynuclear leucocytosis at the time of relapsing feverish attacks), the lymphoma malignum of Kundrat, by the absence of excessive malignancy and of the characteristic histological form. Thus there remained only lymph gland tuberculosis, and in favour of this were hereditary taint, tuberculin reaction (very uncertain, however), the whole "habitus" of the patient, the richness of the pleural exudation in lymphocytes, and the histological characteristics. The prognosis as regarded life was unfavourable, as the great loss of fluid was of importance, quite independent of the pressure, which would lead to permanent injury to the heart and lungs. Treatment had to be limited to good nursing and timely removal of the fluid.

Hr. STEYRER related a case of

UNILATERAL POLYHYDRURIA.

The case, which was carefully observed, was that of a woman with bilateral pyelitis, in which catheterisation of the ureters was employed. At the moment of the introduction of the catheter into the left side there was an increase in the urine issuing from the right side up to double in the unit of time, which was the opposite of what occurred when the catheter was introduced on the right side and the urine from the left kidney measured.

The molecular concentration of the urine reckoned from the freezing depression was lowered by more than half, as compared with earlier samples. In a short time the original condition, both as to flow and degree of concentration, was restored. The interest of the case lay in this—that when one kidney was irritated (catheter) the other kidney responded with polyhydruria, something which had not yet been explained.

VIENNA, January 2nd, 1904.

EXPERIMENTS WITH NEW DRUGS.

ARISTOCHIN.

STRASS has published the results of the experiments conducted with new drugs at the Wieden Hospital. According to his report aristochin has been used in 15 cases where quinine was indicated with excellent results. Aristochin is a neutral carbonic ester salt of quinine, almost tasteless, and easily borne by the stomach, which agrees with the manufacturers' description.

The first case is an insurance agent, æt. 28, suffering from neuralgia nervi superorbitalis trigemini, as severe matutinal paroxysms. The dose ranges from 0·25 to 0·5 gramme, or 5·1 to 7·7 grs. In this case one gramme doses were given with speedy relief; no recurrence after five days' treatment.

It was used with excellent effect in dyspeptic phthisical cases where quinine could not be borne. It was equally serviceable in gastric disturbance, when chlorosis, anæmia, and cephalalgia were present. It is free from that annoying symptom, quinine deafness; neither has vertigo been observed, which is not uncommon to quinine.

Strass thinks, however, that aristochin has no special advantage over the sulphate of quinine beyond the taste and ringing in the ears. He quite believes Swoboda may have obtained excellent results with its use in children for whooping-cough, &c., &c.

ASPIRIN.

Aspirin was used in 40 cases. This is a salicylic salt with hydrogen atoms from the acetal group. It was used in articular rheumatism as well as muscular in the acute forms with beneficial results. Ischia and lumbago rheumatica were equally relieved, while pleuritis and pericarditis with a similar origin were greatly benefited. The dose ranges from 0·5 gramme to 1·0 gramme five or six times a day. He can discover no special advantage that aspirin has over the salicylate of soda, except the absence of the uncomfortable physiological effect, although this must be affirmed with caution, as he met with œdema of the face in a

female, æt. 19, who had been treated with 5 grammes of aspirin for acute articular rheumatism. A similar sequela is reported by Hirschberg. Others recognise red patches on the head, face, &c., but not on the trunk. The drug is contra-indicated in phthisical fever, as it favours hæmoptysis. On the other hand aspirin has been successfully used in gastro-enteritis and icterus catarrhalis of doubtful etiology.

HEDONAL.

Hedonal was used on 40 patients as an hypnotic which belongs to the series of urethane. The greatest number of cases were pulmonary and cardiac, and a few suffered from neuritis and neurasthenia. The dose is 1 gramme to 1½ gramme. The best effects are obtained in cases of agrypnia or pervigillium. The action of hedonal in cardiac diseases is intensified by the combination of strophanthus, codeia in phthisical, and bromideo in the neurasthenic cases. When given in chronic alcoholism or multiple neuritis with anæmia, it produced excitation and determined the blood to the head, which soon caused the patient to refuse the drug.

MESOTAN.

Mesotan is a clear, yellow, oily fluid, soluble in alcohol and ether, and readily absorbed by the skin. It can be detected in the urine a few hours after administration by the presence of salicylic acid and chloride of iron reaction. It is applied externally mixed with an equal quantity of olive oil with a brush twice or three times a day. It is indicated in all cases demanding salicylate treatment. It is efficacious in rheumatic pleuritis, &c., as well as acute articular disease. Ischias, lumbago, &c., &c., are equally relieved by producing an artificial hyperæmia on the surface, as fomentations, thermophores, or cupping glasses. Mesotan can be well recommended for this action, requiring no drug internally, unless a tonic such as the compound tincture of quinine. He has not found any injury to the kidneys, although it operates very favourably on the heart. Mesotan is useless in cases of arthritica urica and deiormans, as well as gonorrhea and neuritis. He had two cases followed by erythema and other purple rashes. Its use is principally confined to the rheumatic, and may be successful where aspirin fails. A few drops rubbed on to the chest of a phthisical patient at night will produce a flood of perspiration in a very short time—hence the injury. The drug should not be used constantly beyond eight or ten days.

THEOZIN.

Theozin, from theophylin, is a synthetic body of the xanthin series, and has been recommended as a diuretic. This was administered to 35 patients in dropsical conditions. Every practitioner knows how difficult it is to obtain the desired effect when a diuretic is wanted. As a rule every drug is tried in succession with the hope that the next will meet with more success than the preceding one; but, alas! with no better result. This was the disappointment that befel theozin in the first experiments. Further examination and selection of cases proved that it was efficacious as a diuretic and antihydropic, when no disturbance of the cardiac organ was present, or when the blood pressure was not abnormally low. When the cardiac apparatus was deficient or the arterial pressure low no advantage can be obtained with the drug. If the circulation be improved and the tension increased the diuresis will rapidly rise from 500 cubic centimetres of urine to an elimination of 1,500 or 3,000 cubic centimetres. Hence a short course of digitalis or strophanthus before commencing theozin will accomplish the desired effect. Again, the abstraction of the digitalis during the administration of theozin caused the quantity of urine to fall from 2,000 or 3,000 cubic centimetres to 1,000 cubic centimetres in one day; hence it is concluded that in all cases of compensatio cordis the blood pressure must also be considered before the drug is successful. In vitium cordis, theozin is equally useless. Gärtner's tonometer was used in every experiment, by which it was found that when it measured 70 or 80 millimetres of mercury theozin had no effect on the renal secretion. If four or five times this pressure could be maintained, the quantity of urine was correspondingly increased. With this object in view, Schliesinger has combined the dose of theozin (0·2 to 1·0 gramme) with an infusum herbæ adonis vernalis (5 in 150 strength), and obtained the exciting effect of the drug. Minkowski, labouring under the same difficulty, combined theozin with hedonal and obtained the exciting effect also. Of the two the infusum herbæ adonidis is the better. Schliesinger supports his application by quoting Bechterew's experiments with adonis vernalis, that it is an anticonvulsive. There are many cases where azurin or the acetate of potash will be equally beneficial in practice.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

APPENDICITIS.—Mr. MAYO COLLIER operated on a case of appendicitis with features of some interest. The patient was a young man, æt. 19, who during the last eighteen months had had five attacks of pain in the lower abdomen, accompanied by sickness, indigestion and fever. These attacks were diagnosed by Dr. Richardson, of Gosport, as appendicular; he requested Mr. Collier to admit the case into the North-West London Hospital and operate. On admission to hospital the condition of the patient was quite satisfactory, some two months having elapsed since the last attack. On examination of the abdomen, in the right iliac region, Mr. Collier said he could make out a distinct thickening of the appendix, which apparently was movable, and its surroundings were free from trouble. He decided to operate. He made an incision along the outer border of the rectus in the usual position. On opening the abdomen the appendix was easily found, freely movable, without adhesions, and with apparently a perfectly healthy peritoneal covering. There were several distinctly enlarged glands in the mesentery of the appendix, but these were freely movable, and of normal colour. The appendix itself was extremely interesting, in so far as it was absolutely stiff and rigid, resembling almost, as Mr. Collier pointed out, a miniature penis. It was thickened and hard close to the attachment of the caput cæcum coli. After dividing the mesentery of the appendix and removing the affected glands Mr. Collier made a transverse incision through the peritoneum covering the appendix about half an inch from the caput cæcum coli; having divided the peritoneum and muscular coat, he ligatured the appendix and removed it. After disinfecting the lumen of the stump with pure carbolic acid, he replaced the cuff of peritoneum, and sewed it with continuous sutures over the stump. The mesentery of the appendix was next brought together with a fine continuous suture of silk, and the abdomen closed. Mr. Collier said he preferred to close the abdomen by first uniting the peritoneum by interrupted sutures. The sheath of the rectus and sheath of the abdominal muscles were next united, and lastly silkworm-gut sutures were passed through, including skin, fibrous, and muscular tissue. Mr. Collier said the line of

incision adopted was more satisfacory than one more external, because it allowed free exploration and manipulation of the appendix and its surroundings, and was less liable to be followed by ventral hernia.

This case made an uninterrupted recovery without a single bad symptom.

WIRING FRACTURED PATELLA.—Mr. COLLIER operated immediately after on a case of fractured patella of four days' standing. He said that lately he had operated on quite a number of these cases with most satisfactory results, and he looked upon the operation as one of perfect safety, unless under most exceptional circumstances. The present patient, a young man, æt. 24, had tripped up in the street on a piece of orange peel, and on admission to hospital separation of the fragments was so slight that at first the fact of the fracture could not easily be ascertained. The joint was considerably distended, probably with blood. Mr. Collier made a longitudinal incision over the patella down to the tubercle of the tibia, and having drilled the broken fragments, brought them into position with a stout silver wire. The joint was opened by a longitudinal incision external to the patella, the blood evacuated, and the joint carefully cleaned with hot saline solution. Every possible precaution was taken before, during and after the operation to avoid sepsis. The parts were adjusted, and the patient removed to bed, after a splint had been applied.

The subsequent history of this case was unfortunately most disastrous. Forty-eight hours after the operation the edges of the wound and the stitches were swollen, red, and angry; the temperature rose to 102°, and the patient was evidently suffering. The stitches were removed and bloody pus issued from the wound. The joint was apparently free from infection. Twenty-four hours later, however, it was evident that the joint was affected, necessitating free opening up and drainage Things mended for a short time, but it was plain that fresh trouble was in store. The whole thigh became swollen and painful, as the planes of fascia between the muscles had become infected, necessitating a further extensive operation. Mr. Collier said that the only possible source of infection was the previous operation he had done for removal of the appendix, yet at this operation the peritoneum was apparently perfectly healthy, and no pus by any possibility could have gained admission to the instruments or hands of the operator, as none was present. The pathological condition of the appendix was a small healing ulcer with much thickening and engorgement of the lymphoid tissue of the process. He had been careful to avoid handling the removed appendix or stump. His assistant at the operation for appendicitis was not the same as the one for the next operation, yet by some means infection was conveyed from the apparently innocent peritoneal cavity to the cut surface of the knee-joint. He thought that everyone must regret the unfortunate result of this seemingly simple operation, and he considered that it would be as well for surgeons to be warned by the result of this case not to operate on a second patient immediately after operating for appendicitis.

PRINCESS HENRY OF BATTENBERG has headed a subscription list which has been started with the object of raising the £18,000 necessary for extensive reconstruction works and additions to the Royal Isle of Wight Infirmary and the County Hospital.

THE North-Eastern Hospital for Children, Hackney Road, has received a donation of £100 from Lord Amherst of Hackney in reduction of the deficit of £1,100 carried forward from 1903.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d per insertion. 0d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

"SALUS POPULI SUPREMA LEX"

WEDNESDAY, JANUARY 6, 1904.

THE THEATRE FIRE AT CHICAGO.

ON December 30th, a tragedy of appalling character was enacted at the Iroquois Theatre in Chicago. During a performance of "Bluebeard," when the audience was composed mainly of women and children, a fire broke out on the stage, and the asbestos curtain could not be lowered. The house was in darkness and a blind panic ensued, in the course of which many hundreds of persons met with their deaths. The exact number is even yet not definitely known, but there is reason to believe that the death roll will reach a total of six or seven hundred. By an irony of fate the building is of the most modern fireproof construction, and we are forced to the conclusion that the terrible fatality was due not to the fire itself, but to its secondary effects of panic and suffocation. At present the cause of the catastrophe is undergoing rigorous investigation. The city coroner is holding an inquiry. A clear indication of the nature of some of the issues that will be raised may be gathered from the published list of points to which the attention of the jury will be specially directed. They are briefly: (1) Were the steel doors locked when the outbreak occurred? (2) Were those doors opened promptly by the attendants? (3) Why was it impossible to lower the asbestos curtain? (4) Why was no provision made to prevent the lights in the flies from igniting the curtains? (5) Why were the doors shut and the people urged to remain seated? There appear to have been ample exit doors which were not available to the panic-stricken audience, for what reason remains to be disclosed. It is clearly of no use to insist upon safeguards against fire if they are not systematically supervised and tested. An asbestos curtain that cannot be lowered is worse than no fireproof curtain at all, since it furnishes a feeling of false security. It has been stated that the obstacle to the descent of the curtain was the wire on which the "Queen of the Aerial Ballet" flew out over the heads of the

audience. From various statements it appears that fire escapes were defective, control of extra fire exits non-existent owing to the absence or confusion of a special attendant, and other avoidable sources of danger present. The lesson to the American people is indeed a terrible one, and it is to be hoped, as it is to be believed, that this fearful holocaust will bring increased safety to future generations of American sightseers. The calamity, moreover, conveys its lessons to the whole civilised world. Among great disasters of the kind may be mentioned one at St. Petersburg in 1836, with a loss of 800 lives; in 1845 at Canton, China, 1670 lives; in 1846, Quebec, 200 lives; in 1872, Tientsin, 800 lives; 1876, Brooklyn, 400 lives; in 1883, Moscow, 300 lives; in 1883, Bervitzchew, 325 lives; in 1897, Quanton, 230 lives, with many smaller losses. The United Kingdom has hitherto escaped without any greater disaster than that of Exeter in 1887, when 127 lives were lost; others are Covent Garden in 1808, 23 lives; the Cobourg in 1858, 16 lives; the Hebrew Club in 1887, 17 lives; and Gateshead in 1881, 24 lives. For all this comparative immunity we should hesitate to endorse the complacent attitude of the Press in various parts of the country. We have little hesitation in stating our opinion that many of the theatres in the United Kingdom would, in the event of fire, become veritable death-traps. Even in the Metropolis, where the fire supervision of the London County Council of theatres and music-halls has been vigorous, much remains to be done. There are theatres in London at the present moment that are so structurally defective as to constitute a standing menace to the safety of the public. Only recently has the whole burden of responsibility in this matter been shifted on to the shoulders of the County Council. The result of that change was the closing of several well-known theatres, because they were unable to face the outlay deemed necessary by the County Council to render them reasonably safe. The inevitable conclusion is that until within a year or two these theatres were a danger to the public. There can be no doubt that the terrible catastrophe at Chicago will greatly strengthen the hands of the County Council and of kindred licensing bodies all over the United Kingdom in their structural control of places of public amusement. It would be interesting to learn in how many of our own theatres and music-halls at the present moment fireproof curtains are prevented from descending by the fixing of wires for the flight of "aerial queens." Nothing can be done by official by-laws to regulate panic, but at the same time the way of escape must be kept clear of obstacles and every means of prevention provided that can be devised by the art of man.

SANITARY REFORMS.

The decision of the Court of Appeal, delivered on the 21st ult., in the case of the King (Rural District Council of Ballycastle) against the Irish Local Government Board, is, we fear, calculated seriously to interfere with sanitary reforms throughout the country. The importance of the issue at stake brought the case into the Court of Appeal, and now, after eighteen months' litigation, the principle for which the Irish Local Government Board fought has been condemned unanimously by judges whose names command respect, so that the decision may be accepted as the correct interpretation, on the question before them, of the Public Health Act. Our readers are familiar with the fact that there are many districts throughout the country in which sanitary reforms are required, and that one of the first steps in that direction is an abundant supply of good water. In many, if not the majority, of such districts the valuation of the property is so small that a tax sufficient to bear the expense of the introduction of a water supply cannot be imposed which the inhabitants could pay without undue hardship. Under such circumstances the Local Government Board have been in the habit of extending the area of taxation until a valuation was reached that could be taxed without levying a too heavy rate on the people! The Board claimed that they had the right to put the charge anywhere they liked, short of the entire district, and that they alone had the right to determine that question. It was considered necessary by the sanitary authorities and the Local Government Board inspectors that the village of Cashendall, of some 400 inhabitants, should be provided with waterworks, but the Ballycastle Rural Council refused to take the necessary steps to carry out the work. As a result the Board, considering the work necessary, issued a sealed order in September, 1902, to the effect that the entire rural district, with the exception of Rathlin Island and the town of Ballycastle, be taxed as a contributing area. The council contended that the Board had no power under the Local Government Act to put a rate to cover special sanitary expenses on a larger district than would be included in the contributory area under the Public Health Act, namely, the place in which and for whose benefit the scheme was adopted. They supported this contention by proving that when on a previous occasion the Board had made similar expenses Union-at-large charges, they subsequently got an Act of Parliament validating the orders, and that this showed that the Board were themselves conscious that they had, in making general orders of the nature now complained of, exceeded their jurisdiction. The Lord Chancellor gave it as his opinion that "He could not see that Section 2 of the Public Health Act of 1900, which enacted that the Local Government Board might, with the consent of the Rural District Council, determine that the whole district should be the area of charge, had much bearing on the question there, but it indicated that in the opinion of the Legislature the Board had not power under the Act of 1878 to make the whole area of charge." Lord Justice Fitzgibbon, in concurring, said it was "perfectly clear that the Local Government Board order was one of excessive jurisdiction." Thus rural sanitary progress in Ireland is practically arrested until fresh legislative powers are conferred on the Local Government Board, for it is hopeless to appeal to rural authorities to enforce

sanitary measures the value of which they have never realised.

THE DRAFT BILL FOR THE REGISTRATION OF NURSES.

THERE is only one way out of the confusion that prevails in the nursing profession, where good and bad, desirable and undesirable, trained and untrained persons are inextricably mixed up. That way is by State registration. The nurses, actuated by pressure from within and from without their ranks, have gradually established a definite system of qualification, namely, a three years' course of training at a recognised general hospital, and it is essential that women who have obtained a certificate of efficiency after this period of probation should be readily distinguished from those who have not. It is due to them in virtue of their attainments, it is due to medical men who employ them, and it is due still more to the public whom they seek to serve. It is beyond dispute that many incompetent persons, some attached to institutions and some acting on their own account, found their principal claim to the title of "nurse" on the possession of a cap and apron, and though there is doubtless a sphere of usefulness for such persons in attendance on old people and some chronic cases, it is most important that in acute cases, where delicate manipulations and skilled observations have to be made, the medical practitioner should be able to rely on obtaining a competent assistant. For these reasons the State registration of nurses commands our ready sympathy. Now, in order to attain this object the Society for the State Registration of Nurses have drafted a Bill which they have put forward for discussion, and we think we shall be rendering them service by offering some criticisms on points that strike us. The first of these is that the Bill has not been drawn up, as it should have been, by an expert Parliamentary draughtsman. Men who devote their time to work of this kind know all the tricks of the trade, and they know how to guard against loopholes being left by which the provisions of an Act may be rendered nugatory. Now, had this been done, we feel sure that some attempt would have been made to define the word "nurse." We have all of us had to accept the word as we found it, and to the medical and nursing world the name conveys a specific meaning. To the public, however, this is not so. A nurse is a person who lives in the nursery and looks after the children; the person who looks after them when they are ill is a "hospital-nurse." We do not propose that this term should be adopted, but we suggest that either the word "nurse" should be defined and its scope limited, or that the words "of the sick" should be added in brackets. Another difficulty arises from the Midwives Act creating a sub-order of sick-attendants, and it is necessary that nothing in the Act should give a nurse a colourable commission to act as a midwife. We notice that an attempt is made to introduce the term "registered nurse" later in the Act, and that it is proposed (by implication) that the initials R.N. should be used after the name. Can it have struck the framers of the Act that these initials are already sacred to the Senior Service? We think not, or they would have known that every Service member in the House would oppose it. We think that there is much to be said for two distinctive initials being used to designate the nurses on the Register, but R.N. will not do. The next point that we would deal with is the constitution of the Council. Let them take warning from the condition of the General Medical Council and be chary as to how far they secure representation for privileged bodies. Why should not the seats be filled by representatives of the people who pay for its support—the nurses themselves? We see no earthly reason for securing seats to three past or present hospital matrons appointed by the Matrons' Council of Great Britain and Ireland. This Matrons' Council is a new body, and in ten years' time may not exist, or may be merged into some other society. Let the right to seats be as free as possible to those whom the nurses think will best voice their own views. There are several verbal alterations that it would take too long to deal with, but we must draw attention to the power that it is proposed to give the Council to strike a nurse's name off the Register (why "Roll" in one place and "Register" in another?) for disobeying the regulations of the Council *or other misconduct*. The italics are our own. This power is far too wide, and as it is possible that it may be exercised by a Committee of three persons it would open the door to much that might be most undesirable in the way of personal bias. The misconduct should be specified. We wish the Bill well in its aims and general scope, but there must be considerable pruning and trimming before it would be safe or wise to allow it to appear on the Statute Book.

Notes on Current Topics.

Patent Medicine.

A LECTURE of considerable interest and importance to the medical profession was recently delivered by Dr. Robert Hutchison, at the London Hospital, on the prevalence of, and the abuses arising from, the use of so-called patent medicines by the public. This is a subject to which THE MEDICAL PRESS AND CIRCULAR has frequently directed attention. It is, to say the least of it, a scandal that the patent laws should be so twisted away from their original purpose that any fraudulent-minded individual is enabled to pose before the public as an inventor and to raise some combination of drugs—perhaps harmless, or perhaps the reverse—to a level with the invention of practical and of scientific minds in the eyes of the general public. The essential of a patent of any kind—we use the word in its correct sense—are, first, that it shall be original, and secondly, that such a description of it shall be placed on record that a person of sufficient intelligence can, as soon as the law permits him to do so, reconstruct from the description filed the particular article patented. For some extraordinary

reason, it is quite apparent that neither of these conditions need be fulfilled by the patentee of a so-called patent medicine. There is nothing to oblige him to show that his nostrum is original, and, far worse, there are no attempts made to compel him to file a full specification of its contents. That these obligations might at times be allowed to go by default in the interests of humanity is possibly very proper—if a case of such a kind could arise—but that such exemptions should be permitted in order to facilitate imposture, when they are denied to the *bonâ fide* inventor, does not seem to be either good or fair policy Its results are obvious to every practising physician and to every pharmaceutical chemist. A shoal of harpies pick out each one his particular nostrum, give it its fascinating title, pay the necessary fees, and launch it on the sea of commerce with the possession of a Government stamp, and the implied recommendation to many simple folk that it is thereby vouched for and guaranteed by Government. As Dr. Hutchison says, persistent and audacious advertising precedes and follows the advent of the compound with the object of creating in the minds of the public an exaggerated dread of disease and an illogical idea of the value of the vaunted remedy. Every right-minded man condemns journals and newspapers who publish, for the sake of gain, immoral and filthy advertisements; when will they also see that for Government to directly aid the sale of "patent medicines" for revenue purposes—as is at present done—is a very similar procedure?

Action for Malpraxis.

It is not generally known that the right of a patient or his representatives to an action for malpraxis against an unskilful physician has been recognised as far back as the days of Ancient Greece and Rome. Yet we find one of the first recorded cases occurring at Ephesus, when a certain physician named Glaucus was condemned to death by the cross because, having left a patient in order to go to the theatre, the patient imprudently partook of food during his absence, and died. In Rome there were stringent laws punishing carelessness or ignorance on the part of the physician, but they seem not to have been rigorously enforced, for we find Pliny complaining that to a doctor alone is it permitted to slay with impunity. According to ancient Germanic law, a physician before attending a patient had to guarantee an indemnity in case he was not successful. If he wounded a free man to his hurt while bleeding him he had to pay the sum of one hundred and fifty golden ducats, while, if the patient should die, the physician became the property of the family, who could deal with him as they thought fit. In French law from the Middle Ages down one finds various references to the liability of medical men, and there are many records of suits for malpraxis which show that in the main the doctrines held were the same as those now in force. In England under the Stuarts severe measures were often used against quacks and nostrum-dealers, and in the reign of James I. the magistrates of the City of London were ordered to hale all empirics before the Censors of the Royal College of Physicians for examination. A little earlier than this we find a certain Arthur Dee punished for advertising medicines to cure all diseases, and one Foster for selling a powder to cure chlorosis, while a person named Hunt was put in the pillory for putting bills in the streets for the cure of diseases. The proprietors of various "pink pills" and "safe cures" have reason to congratulate themselves that they did not live two or three hundred years ago, though the public of to-day have not the same reason to be grateful.

Bacteria and Cold.

It has long been held that exposure to prolonged cold is fatal to most pathogenic bacteria, and in particular to the typhoid bacillus. While it was known that a short exposure even to intense cold, such as that of liquid air, was insufficient to do more than inhibit their growth, yet many observations had gone to show that when bacteria were exposed for days or weeks to a temperature below freezing point, they died. In an exhaustive examination of the ice supply of Boston made some years ago by Drs. Sedgwick and Winslow this view was borne out, and these investigators came to the conclusion that ice more than three weeks old was sanitarily as safe as well filtered water. Some recent epidemics have, however, shown facts startlingly at variance with the accepted views, and of great importance to public health, particularly in America, where the consumption of ice is much greater than here. In the case of the St. Lawrence epidemic which occurred twelve months ago, the outbreak started with the consumption of ice from a certain ice-house where it had been stored for eight months. The water supply and food were above suspicion, and the ice was made the chief object of investigation. Very simple culture experiments were sufficient to establish the presence of both typhoid and colon bacilli, showing unquestionably the presence of sewage contamination. Further inquiry elicited the fact that at the time the ice was forming the previous winter there had been a few cases of typhoid in its vicinity. There seems no reason to doubt, then, that whether it be unsuual or not typhoid bacillus has the power of resisting low temperature for many months.

The Religion of Poor-law Nurses.

Poverty knows no religion, as it spares no rank. Among the host of human wreckage to be found within the shelter of the Poor-law of the United Kingdom are representatives of every kind of religious belief and unbelief. This diversity of forms of worship is so characteristic of the national character that it has become recognised on the Continent in the proverb that "The British are a nation of many religions and one sauce." The inevitabie in this respect has been hitherto wisely accepted by the Local Government Board in their Poor-law administration. Officials have been selected regardless of their religious beliefs, and opportunities provided for bringing services of various kinds as far as possible within the reach of the Poor-law population, whether administrative

or pauper. In the course of time, however, boards of guardians are apt to forget the traditions and principles that have guided their predecessors. That appears to have been the case at Eccleshall, where the question of religious tests has been raised in an acute form as regards the Poor-law nurses. It appears that the superintendent of nurses declined to obey the order of the guardians to attend divine service on Sunday morning. Her refusal was simply a matter of conscience, as she had on several occasions attended the service voluntarily. The guardians after some heated discussion referred the matter to the Local Government Board. It would be inconceivable that any answer could be returned from the central authority other than that any Poor-law official is entitled to decline attendance at a religious service not in accordance with his own views.

Poisoning by Methyl Alcohol.

WE have noticed in many medical journals recently, particularly in our American exchanges, a number of cases of poisoning reported as due to Jamaica ginger. In fact, this apparently harmless article of diet has come to be regarded with so much suspicion that we understand there are at present several law-suits pending in which damages are claimed against ginger manufacturers for alleged poisoning. In every case reported the symptoms followed on the drinking of a spirituous essence of the ginger, but were of varying severity. In mild cases there were no further symptoms than a certain amount of gastro-enteritis, while in more severe cases there was partial loss of sight and even complete and permanent blindness, and in very severe cases blindness was soon followed by coma and death. About the same time, however, as these cases of alleged ginger-poisoning were occurring, there were a number of other cases of poisoning reported with exactly similar symptoms. For them different substances were blamed, lemon extract, essence of peppermint, columbian spirits, bay rum, and finally methyl alcohol. Dr. R. H. Main, of Berry, Illinois, who reports a case of his own and collates the references, (*a*) has not much trouble in showing that in all probability the common feature in all the cases was the presence of methyl alcohol, which is often substituted for methyl alcohol in the preparation of culinary and medicinal essences. The only reason that it has not long ago been tabooed is apparently the fact that its effects are very varying in different individuals. "Suppose," quotes Dr. Main from Dr. Casey Wood, "six men consume equal quantities of any liquor containing, say, eight ounces of methyl alcohol, one of them will probably die within forty-eight hours of marked intestinal and cerebral symptoms; one other will be very ill, but recovering, will become totally blind in a few weeks, while the other four will suffer as from a drunken orgie with ordinary alcohol." Taken in the small quantities used in cooking, methyl alcohol is probably innocuous, but taken as it frequently is in the so-called "dry towns"—*i.e.*, in Prohibition districts, in quantities from a drachm to an ounce or more, its toxicity is, as the above description shows, very considerable and dangerous.

(*a*) *American Medicine*, September 5th, 1903.

The Dangers of Coke Fires.

IN these days of progress it is, indeed, quite the exception to find a main road within the Metropolitan area which is not in the hands of some contractor or other. Here it is the electrification of a tram route, and there it is the repair or adjustment of one of the many systems of pipes with which the great city is literally honeycombed only a few feet below the surface. The lot of the many workers engaged upon these tasks varies, of necessity, with the exigencies of the weather. Cold and other hardships are comparatively easy to endure as long as the body is engaged in active work. It is otherwise, however, with those whose duties are to guard the works at night. They cannot perambulate the field of labour the whole night long, and, therefore, some provision must be made for their shelter and warmth. At best, this usually consists of a three-sided wooden erection in which, sentinel-fashion, the lonely night-watchman sits before a coke fire, and, as long as the fumes are not blown into his box, he is fairly comfortable; but the wind does not always blow from the same quarter all through the night, and then the whole concern has to be moved with much labour. At other times the shelter is made up of a wall of bricks covered by a tarpaulin, which is often devoid of any means of ventilation, so that the interior quickly becomes fouled by fire- or tobacco-smoke and the emanations from sundry oil-lamps. The recent death of one of these men shows that a distinct danger exists in the present means of accommodation. The medical evidence at the inquest was that the deceased was overcome by the fumes from the stove, and falling forwards in an unconscious state, had been burned. It should not be impossible to provide movable "sentinel-boxes" so that they could be turned in accordance with the direction of the wind, for, not unfrequently, they are so placed as to render any change in position a physical impossibility.

The Function of Maternal Milk.

To the student of comparative anatomy few things are more interesting than the manner in which the needs of the young growing organism are provided for. We are so accustomed to regard milk as the natural food for the young of the higher animals, including man, that its true function and properties in this respect are apt to be forgotten. A valuable paper upon the subject has recently been read by Dr. H. Dwight Chapin at the Pediatric Section of the New York Academy of Medicine, in which the idea is expressed that maternal milk, in addition to nourishing the offspring, actually assists in the development of the infantile stomach. In reviewing the various forms of the alimentary canal from the standpoint of comparative anatomy, Dr. Chapin finds that in the kangaroo a considerable change takes place in the digestive tract during the period of suckling. The distinctive

composition of colostrum, as compared with the milk which is later secreted, is well known, and this fluid has been credited with possessing certain properties by which the immature gastric mucous membrane is prepared for the stronger material to follow. It is suggested that maternal milk contains proteids, the function of which is to provide nutriment capable of easy absorption at a time when the stomach is not in a condition to undertake proper digestion. As the infant's digestive organs become further developed, longer intervals between the feedings are rendered necessary. The mutual adaptation of the mother's milk and the secretions of the child's gastro-intestinal tract is also striking. From these observations, Dr. Chapin concludes that a rigid adherence to any particular rule for infant feeding will only be fraught with disaster. The whole state of the infant's digestive powers must be taken carefully into consideration, and something more than a haphazard mixing of milk with some diluent is required.

Diphtheria Antitoxin in Private Practice.

THE use of antitoxin in the treatment of diphtheria is at the present day so well established that there is no longer any need to adduce statistical evidence in its favour. Nevertheless, the mortality rate is still so high, if judged from official figures, that one must question whether mere statistics give at all a favourable enough opinion of its merits. The average practitioner, indeed, is rarely convinced of the utility of a certain method of treatment by a mathematical comparison of mortality rates, for he is a practical man, and he judges from his own experience, and from what his neighbours tell him of theirs. It is fortunate that this was his method of forming an opinion in the case of diptheria antitoxin, for if he had proceeded otherwise, he would not have been so likely to come to a correct decision. Judging from official figures supplied by various health authorities, the mortality rate in diphtheria is still somewhat over ten per cent. In America, different States and cities give returns varying from seven to fourteen per cent. In Germany the figure stands still higher, between sixteen and seventeen. In England a fair average would be about fifteen per cent. With a view of comparing these official rates with the results in private practice, Dr. Zahorsky, of St. Louis, has just made inquiries (*a*) from twelve of the leading physicians in that city, whose practice lies chiefly among children. Among 1,610 cases of diphtheria attended by these gentlemen during the past five years, there have only been 24 deaths, giving a mortality percentage of 1·5. This contrasts so markedly with the total returns we have quoted that one cannot help questioning whether the antitoxin treatment is as widely adopted as we are wont to believe, and as it unquestionably deserves. Granting that the St. Louis physicians have an advantage over the average practitioner in that their practice lies probably among the better classes, and that therefore they see patients earlier in the disease, nevertheless the difference of results is still too large to be easily explained. The success of these twelve gentlemen, however, is very encouraging, and it should be the aim of every practitioner to assimilate his figures to theirs.

(*a*) *Medical News*, December 5th, 1903.

An Epidemic of Pseudo-Rabies.

WHAT at first sight appears to be a terrible outbreak of rabies has taken place at Madrid, there being no less than twenty persons reported to be suffering from hydrophobia. Among the number is a man who was bitten by his son, who had himself contracted the disease from the bite of a schoolfellow. No mention is made of one or several mad dogs, and on investigation of the circumstances it becomes evident that although the alleged outbreak owed its origin to one or two possibly genuine cases of hydrophobia, the other cases are in all probability of the nature of imitative hysteria or "hydrophobia by suggestion," especially in view of the benignity of the affection. It used to be believed—indeed, the belief is still very generally entertained by the non-medical—that fear may *per se* engender hydrophobia, and instances have been placed on record in which this pseudo-hydrophobia actually proved fatal. It is obvious that the supervention of grave symptoms in such cases must be due to complications, as, for instance, to meningitis or other acute cerebral disease. Morbid scare is very epidemic in its incidence, and in presence of a hydrophobic scare many persons of unstable nervous equilibrium forthwith develop symptoms which pass muster for hydrophobia just as every rise of temperature and every malaise is ascribed to influenza when that disease happens to occupy the minds of men. Now hydrophobia is usually considered to be so inevitably fatal a disease, once it admits of diagnosis, that the fact of recovery belies the diagnosis. The mental excitement and physical depression which, in certain subjects, follow the bite of a dog are eminently calculated to fan into activity any latent meningeal or cerebral weakness. At the same time, an error of diagnosis ought not to be possible in regard to the merely hysterical phenomena.

More Light.

TENNYSON'S infant crying for the light would have had his appetite surfeited had he lived in these days, for rays and radiating substances succeed one another with bewildering rapidity. The people who have so pertinaciously clung to belief in thought-transference must be greatly comforted when they read every six months of some new and unsuspected emanations from things organic and inorganic. The day of their justification seems to be at hand. The latest thing in rays again comes from France, M. Blondlot, of the University of Nancy, having discovered them proceeding from the human muscles and nerves. In compliment to the town that provides him with his chair he has called them the N-rays, and he finds that they can pass through black-paper, aluminium, and several other substances. If this discovery is confirmed by other

physicists and physiologists, a very extensive field will be opened up for further research, for an entirely new method of studying the action of the nervous system in health and disease will be available. "Functional" nervous diseases have been equally the puzzle and bane of physicians almost since medicine recognised a nervous system as existing, and one can have little doubt but that these are due to minute molecular changes in the neuron. If the N-rays given off by the nerves are found to throw any light on these conditions, one can only hope that M. Blondlot will receive the Nobel Prize next year, as Finsen and the Curies have this, for he will have helped to remove one of the greatest disabilities under which the science of medicine at present works.

A Pioneer Association.

THE twelfth annual meeting of the Liverpool Ladies' Sanitary Association reminds one that the excellent example set in the Northern city has not yet been followed by ladies elsewhere as it might have been. The objects of the association are to encourage and develop sanitary work, to rouse public interest in the necessity for preventing disease, and to raise the moral tone of the population by improving their surroundings. For these purposes the services of the ladies of the town are enlisted and organised, and the value of the unofficial aid thus rendered to the cause of public health cannot well be over-estimated. Apathy among the people themselves is almost a greater drag on sanitary progress than misdirected zeal, and an association of this kind combats both these social difficulties. The association trains health-lecturers and children's nurses, and itself delivers a number of free lectures on questions of health. The Chairman of the association is a clergyman and thus the co-operation of religion with sanitary reform is secured, to the great advantage of both. It is to organisations of this character that one must look, far more than to Acts of Parliament and by-laws of local authorities, to diffuse knowledge among, and gain the adherence of, the people themselves, who, after all, are the ones to be reached. Combinations of the ladies of all towns and large districts modelled on the lines of the Liverpool Ladies' Sanitary Association could work wonders in the slums and alleys, for does not the hand that rocks the cradle rule the world? The only objection to the association is its name. "Sanitary" always suggests "drains," and drains are objects of popular contempt and derision. Could not some more sympathetic title be devised?

The Plumbers' Company and Registration.

THE question of the registration of plumbers is fast assuming a position of importance in practical politics. It is one that concerns the public health in no small degree, inasmuch as a great deal of the sanitary comfort and safety of the citizen lies in the hands of the plumber who controls his water supply, his drains, and many details of his internal domestic architecture. The influential Plumbers' Company—an ancient London body—have for many years past worked steadily with a view of obtaining from Government compulsory powers of registration of all plumbers. During the past year they have presented a petition to Parliament in favour of the proposed registration signed by 3,500 master and operative plumbers. The wish to obtain good work from known and responsible workmen is laudable enough, but there are other things to be considered in the interests of the public. There is the question, for instance, whether the establishment of a combined monopoly controlled by the Plumbers' Company would not raise prices of plumbing work unduly. Then the reflection arises: why should not carpenters and cabinet-makers and a number of other skilled workmen be controlled in a similar manner? In short, the registration proposals of the Plumbers' Company involve issues of such general and special importance that we propose at an early date to discuss them somewhat fully.

Cures—Ancient and Modern.

THAT the appetite of the public for marvellous "cures" grows with feeding may be assumed from the unceasing supply of novelties of the kind that are "boomed" in the daily newspapers. One day we are assured tht a maniac suffering from violent dementia was "cured" after an hour's isolation in a blue room, and another grew peaceful after a day in a violet room. To restore reason to the degenerate brain of a "dement" is a task left to the omnipotent journalist, for it has long ago been abandoned as hopeless by the medical profession. An amusing instance of re-discovery of an old form of treatment has recently gone the rounds of the Press in the shape of the "hot water cure" for typhoid fever. A leading journal gravely writes that it is one of the latest "cures," and that it has recently been tried at the London Hospital. The reduction of febrile temperatures by the continuous bath has been before the profession for the last half-century or more. At one time the method was extensively used in the treatment of typhoid and scarlet fevers, and of hyperpyrexia generally. To the modern journalist nothing is sacred. He seems, however, to be deriving a good deal more "copy" from the hospitals than he is entitled to in the ordinary course of his occupation. The hospital authorities would do well to keep a tighter hand on the information conveyed to journalists.

A Case of Hellebore Poisoning.

A GOOD deal of scientific interest is attached to the case of an old army pensioner named Davis at Sackville College, East Grinstead. An inquest was held on December 22nd last by Mr. G. V. Benson, the East Sussex coroner, and resulted in a verdict of accidental death through poisoning by hellebore. Deceased was suffering from pains in the stomach and went to his room with the intention of taking some liquorice powder. Half an hour later—at seven in the evening—he returned saying he had taken hellebore in mistake for liquorice powder. He then went to a chemist, whose shop he reached about 7.30. He was advised

to go to a doctor, and walked away looking " as if nothing were the matter with him." Shortly afterwards he was found in a helpless condition in the road and taken home, where, after violent pain and convulsion, he died at a quarter past eight. Unfortunately medical aid was not available. In October last deceased bought the hellebore at a local chemist's for the purpose of making an ointment to allay an irritation of the skin. The hellebore, liquorice powder, and some Epsom salts were kept together in a tin. Black hellebore or Christmas rose is used by horticulturists as a vermifuge and insect killer. Although so deadly a poison it is not on the schedule, and the chemist who sold the drug acted in a praiseworthy manner in entering the sale in his poison book. His wisdom in selling the hellebore, however, may be called in question, as well as the casual way in which the old man was referred to a doctor on stating his mistake. Poisoning by hellebore is extremely rare, so that the data of the above case will be of value to toxicologists.

The Contagiousness of Alopecia Areata.

MANY disputes have arisen concerning the origin of that form of baldness known as alopecia areata, or the area Celsi. Though no actual specific micro-organism has been discovered in connection with the disease, yet there are many who firmly believe that it is a bacterial affection, and, now and then, cases are brought forward which seem to uphold the theory. Others, on the contrary, maintain that the cause lies in the nervous system, and that the fall of hair is due to trophic influences acting through the peripheral nerves. It is well known that a sudden and severe mental emotion may produce this form of alopecia with great rapidity, such as could not very well be supposed to result from the action of a germ. M. L. Jacquet, one of the champions of the trophic theory, not so very long ago traced the development of the disease to carious teeth, believing that the irritation thus set up produced a sort of reflex alopecia. The same observer has recently recorded (*a*) the results of one hundred separate attempts to inoculate the disease upon healthy scalps. The subjects experimented upon included five of his pupils at the Hôpital Saint-Antoine and himself, upon whom M. Sabouraud personally conducted the inoculation. The material derived from scraping the margins of the bald patches was inserted by means of a hollow needle directly into the hair-follicles of the normal scalps. In the case of M. Jacquet, he purposely abstained from all toilet of the scalp for forty-eight hours, in order to give the supposed parasite full chance of finding a suitable nidus for its growth. All the experiments were entirely negative. Though not, of course, absolutely conclusive evidence against the theory of contagion, these facts cannot be said to support it very strongly.

THE strong human note struck by Mr. Luke Fildes in his well-known painting of " The Doctor " renders that work of especial interest to the medical profession. The sale of engravings of the picture has been enormous, with the inevitable result that the English market has been swamped by a flood of copies " made in Germany." We have been asked to warn our readers against this unfair substitution. The effectual safeguard against any such fraudulent practice is to bear in mind that the genuine copyright engraving of Mr. Fildes' picture is published by Messrs. Thos. Agnew and Sons, of 39B, Old Bond Street, London, W.

(*a*) *La Presse Medicale*, December 12th, 1903.

PERSONAL.

MR. JOSEPH T. FRY has made a Christmas gift of £1,000 to the Bristol General Hospital.

EARL HOWE, as Chairman of the Birmingham Triennial Musical Festival, was able to hand over nearly £1,000 to the General Hospital of the town mentioned as the profits of the recent festival.

DR. CHANTEMESSE has been appointed Inspector-General of Sanitation in Paris, in succession to the late Professor Proust. Dr. Chantemesse, it need hardly be added, is a bacteriologist of note, who has made a special study of cholera and typhoid fever.

A SERIES of handsome presentations were made recently at the Velingwm County School to Dr. Glanville Morris, Medical Officer of the Maerdy Collieries District, by admiring friends and patients.

AT the next meeting of the Incorporated Society of Medical Officers of Health, to be held in London on Friday, January 8th, Dr. J. Spottiswoode Cameron will open a discussion on Sophistication of Foods.

HIS MAJESTY THE KING has graciously appointed to the Fourth Class of the Royal Victorian Order Mr. Harold Boulton, honorary treasurer of the Queen Victoria's Jubilee Institute for Nurses.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

BELFAST.

EQUIPMENT OF QUEEN'S COLLEGE.—A strongly-worded memorial has been sent to the Chief Secretary for Ireland by the Council of the Belfast Natural History and Philosophical Society, calling the attention of the Government to the urgent need of increasing the provision for scientific teaching and research in Queen's College, Belfast. They state their belief that the need of Belfast is greater than ever, and may be dealt with quite apart from the long-delayed settling of the general university question.

THE CONSUMPTION QUESTION.—At the monthly meeting of the Belfast Corporation on the 1st inst., a report was presented by the Medical Superintendent Officer of Health on the prevalence and proper treatment of consumption in the city. From 1893 to 1902 the deaths from consumption varied from 977 to 1,132 in the year, on the whole showing a tendency to decrease in proportion to the population, and being about one-seventh of the total number of deaths each year. The estimates of the total number of consumptives in the city at any one time vary from 2,000 to 4,000. The report goes on to recommend the provision of open-air shelters in the neighbourhood of the city for mild cases, and a sanatorium for more advanced cases. This latter, if built of brick, to accommodate 100 patients, would cost £25,000 to £30,000 to erect, and to maintain would cost £50 to £60 per bed per annum. Wooden buildings, however, could be erected in blocks,

each capable of holding twenty patients, at a cost of £1,000 each block, and the cost of such a sanatorium for 100 patients, with administrative block complete, would be about £8,000. The necessity for great care in the choice of a site is dwelt upon. Compulsory notification of cases is advocated. Since last May the Belfast Dispensary officers have voluntarily and gratuitously notified cases, 143 in all, and in every instance the house where the patient lived was visited by one of the female sanitary inspectors and advice and instruction given. The report will be considered in detail at a future meeting of the Corporation in committee.

HEALTH OF BELFAST.—The health of the city seems to have been remarkably good during the past year, the death-rate for 1903 being only 19·8 per 1,000, the lowest on record. From typhoid the death-rate was 3·8 per 1,000, the lowest since 1888, when it was 3·3. In 1898 it rose to 18·8. From zymotic diseases the death-rate was 2·2 per 1,000, the lowest for sixteen years, with the exception of 1900, when it was 2·1. Typhoid shows a marked decrease last month, but whooping-cough and scarlatina are both very prevalent. In the last four weeks there were notified 75 cases of scarlatina, 48 typhoid, 48 erysipelas, 23 diphtheria, 20 simple continued fever, 9 small-pox, 5 membranous croup, 4 puerperal fever, and 3 typhus.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—When I wrote to you the letter you were good enough to publish December 9th on Vivisection, the question of interest seemed to me to be to ascertain what evidence could be given by any of your readers of their own personal experience in vivisection as a source of useful practical knowledge. Most of us who take any interest in medical education, and in the value of vivisection, know pretty well what the great men of the past learnt from it. We do not want any references to this kind of evidence, one way or the other. We want an answer to the simple question, "What have you learnt from vivisection, you yourself, from your own experiments first, and from what you have seen others do next?"

We know too well how sentiment is often an antagonist to research and progress, whether it be religious sentiment or dread of pain, or any other of those peculiarities in the nature of human beings which we cannot dislike or despise, and which we must often admire and respect. Cruelty is a low, mean, despicable trait in a man's or woman's character, and we are justified in observing how we give it liberty to do harm.

I see no such trait in the character of the great physiologists and anatomists of the past; such men as William Harvey, the Hunters, and later Pasteur, Charcot, and some who have done much in the study of disease. Personally, I dislike and distrust vivisection as a method of research. The dissecting room and the post-mortem room have always appeared to me to be the most certain and satisfactory fields for laying the best foundation for good practical knowledge. To watch the capillaries of a frog's foot or a fish's tail is not cruel, or need not be, and it is certainly interesting, and if the anti-vivisectionists only ask for care that there is no pain or cruelty inflicted, we cannot think them wrong. But to go back to the question of interest, I have not found vivisection reliable, and I will give an instance of this. Many years ago when I had the direction of the post-mortem room and the teaching of pathology in one of our hospitals, my friend, the lecturer on physiology, brought into my room a rabbit that he had been lecturing on, to show how the division of the sympathetic on the left side affected the temperature of the ear, the condition of the left iris, and other peculiarities related in works on physiology. I thought the kindest thing to do was to have the poor creature killed, and I put it aside after proper cleaning in pure alcohol to dissect it. I was rather amused to find that so far as the sympathetic ganglion, which lies deep in the neck close to the pneumogastric and phrenic, was concerned, it had not been reached by the section made by my friend, and not even approached, and consequently I was rather led to think that there was not much reliance to be placed upon that kind of physiology, or upon those who believed in it.

It seems to me that if we disturb in the slightest degree the natural, harmonious, and most complicated relations of the parts of a living creature by even the slightest injury or influence, we cannot be certain of what we observe, particularly when the work we are doing is outside the simplest physical science. It was with interest that I tried to find out what Charcot learnt from vivisection compared with pathology. Disease has always seemed to me to be of infinitely greater value to physiology than any but pathologists can realise. When the lecturer on physiology at any of our schools is not a good pathologist and good anatomist, in my opinion he cannot be a good teacher of physiology.

Let us not misdirect the studies of our students, considering how short a time they have to learn what they ought during student life, from the practical, useful, and absolutely necessary knowledge they should acquire to fit them for the work they are preparing for.

I am, Sir, yours truly,
ROBERT LEE.

[The fallacy of non-division of the sympathetic ganglion in the experiment, assuming division to have been the intention of the experimenter, and further, that the objective signs mentioned were present, surely furnished data for revising former recorded experiments—and in that way justified the experiment, provided always that the fallacy came to the experimenter's knowledge.—ED.]

"CURES" FOR CONSUMPTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The editorial paragraph on the above-named subject in your issue of to-day, December 30th, serves to remind us that we have never had any final report from Colonel le Poer Trench, with regard to the investigation into the nature of the "Lacnanthes Cure," of which two or three years ago he made himself champion. In the interest of science, of the public, and perhaps as a contribution to the history of popular medical errors and delusions, it is important the story of this "cure" should be fully told; whilst in justice to the medical profession, against whom, as a body, wild charges of persecution for selfish ends were made by advocates of the "cure," it is desirable these charges should be substantiated or withdrawn.

I am, Sir, yours truly,
H. S.

December 30th, 1903.

[Our correspondent has drawn attention to a point of importance. The subject should not be permitted to lapse into the No-man's Land of the unknown and the uninvestigated, which already forms the abiding place of too many "curers" of grave and incurable disease.—ED.]

"A NEW TREATMENT FOR BOILS."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The idea of injecting one or more litres of oxygen gas subcutaneously for the cure of boils and carbuncles related by your French correspondent in THE MEDICAL PRESS AND CIRCULAR for December 16th is only an extension of the "oxygen treatment," and open to the same general objections of inconvenience and expense.

I have had considerable experience of the treatment of boils, in myself and others, and I can certify that if the boil be treated at the onset by removing the

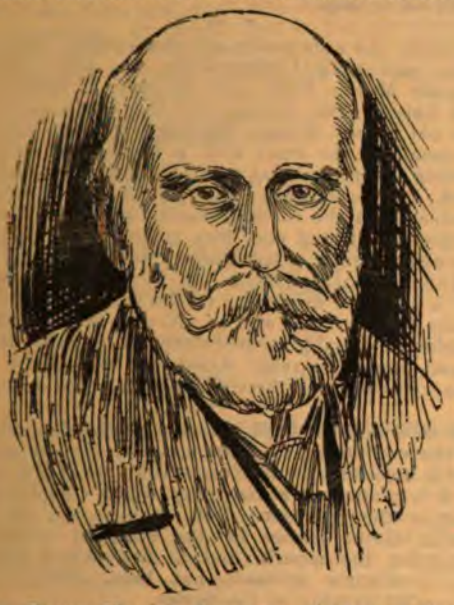
apex with the point of a scalpel, squeezing out the minute quantity of pus therein contained, and then cauterising the interior of the small cavity with pure carbolic acid, that boil will never go any further. I have never seen this treatment fail, and I have applied it in many dozens of instances.

I have remarked, however, that if the application of the acid be delayed until the boil has attained the dimensions, say, of a cherry, its success is less certain. Some practitioners evince a dislike to opening these troublesome formations, but from personal experience—acquired prior to my adopting the abortive method—I can testify to the comfort which free incisions, followed by free curetting of the sloughing tissues and the free application of the pure acid, affords. I convinced myself, moreover, that by such means the duration of the boil, whatever its dimensions, is materially curtailed. The method is so simple and so certain that I am surprised it is not more generally adopted.

I am, Sir, yours truly,

Mustapha-Supérieur, Algiers. ALFRED S. GUBB, M.D.

PRESENTATION TO A PERTHSHIRE SURGEON.



DR. DAVID HALKET STIRLING, of Perth, who has recently celebrated his jubilee as a member of the medical profession, was entertained by the Perthshire Branch of the British Medical Association and presented with his portrait, a striking likeness, painted by Mr. C. Sellar, R.S.W. A photograph of the picture has been prepared by Mr. Mercer—of the Raeburn Studio, Princes Street—for the subscribers, and will be acceptable to Dr. Stirling's many friends. The movement has been confined entirely to the medical profession. By the courtesy of the *Dundee Advertiser* we are enabled to produce the sketch of the presentation picture. Dr. Stirling graduated as M.D. of the University of Edinburgh. During a long and distinguished career he has filled numerous honourable positions both in a professional and in a civil capacity. The honour and affection testified to so cordially by his medical brethren are faithfully reflected by an unusually wide circle of friends and acquaintances in the world that is outside his purely professional life.

Obituary.

DR. CHARLES F. MOORE.

WE deeply regret to announce the death of one of the oldest, if not the oldest, practising member of the medical profession in Ireland. Charles F. Moore entered the medical profession in Dublin through the medium of the Apothecaries' Hall, in 1843. In 1844 he became a Licentiate of the Royal College of Surgeons and an M.D. of Glasgow University, and in 1865 he passed the necessary examinations for the Fellowship of the Royal College of Surgeons in Ireland. Dr. Moore has thus been a member of the medical profession for some sixty and odd years, and in spite of his age a fortnight ago was still discharging his duties as certifying factory surgeon for the Dublin district. The late Dr. Moore's life was a busy one. Early in his career he served as ship's surgeon, and for several years was a senior surgeon in the Peninsular and Oriental Steam Packet Compay's service. After he had given up a sea life, he settled in Dublin, where for many years he held the post of medical officer of health to the No. 3 South City Dispensary. In addition, he was a visiting physician to Cork Street Fever Hospital, medical inspector of seamen for the Port of Dublin, and certifying factory surgeon for the Irish Metropolitan District. Dr. Moore devoted much attention from the outstart of his career to sanitary science, and contributed several articles to the medical journals on subjects relating to the public health. During his time at sea he acquired much information regarding tropical epidemic diseases, and this knowledge materially assisted him in discharging his duties in Dublin in connection with the inspection of seamen, and widened his opinions on the importance of preventive medicines. Dr. Moore always took a keen interest in the work of the Public Health Section of the Royal Academy of Medicine in Ireland, of which section he was at one time President, and in the work of the Sanitary Association and the Society for the Prevention of Tuberculosis. In his private life Dr. Moore won the regard and affection of all with whom he came in contact, and many will learn with sorrow that he has passed away to join the numerous colleagues and friends whom he had seen precede him.

LIEUT.-COLONEL EDWARD RUSSELL CREE, R.A.M.C.

WITH regret we announce the death of Lieut.-Colonel Edward Russell Cree, R.A.M.C., on December 29th, of heart failure, at Wokingham. The son of the late Edward Hodges Cree, Inspector-General of Hospitals and Fleets, R.N., he joined the Army as a surgeon in 1880, becoming surgeon-major twelve years later, and lieutenant-colonel in 1900. Lieut.-Colonel Cree served in the Soudan campaign in 1885, and was present in the engagements at Hasheen and the Tofrek Zariba, and at the destruction of Temai, receiving the medal with two clasps and the Khedive's Star. In the South African War he again saw service in 1899 and 1900, and took part in the relief of Ladysmith, being mentioned in despatches. Lieut.-Colonel Cree was 45 years of age.

DR. ROBERT JAMES BLAIR-CUNYNGHAME.

By the death of Dr. Robert James Blair-Cunynghame, of Crouan, Perthshire, who died last week at Rothesay Place, Edinburgh, a prominent Scotchman has been lost to the profession. He was born in 1841, and was educated at the University of Edinburgh, and in London, Berlin, Prague, and Vienna. He took the M.D. degree at Edinburgh in 1862, when he was Gold Medallist in Forensic Medicine; was admitted a Fellow of the Royal College of Surgeons, Edinburgh, in 1866, and a member of the Royal College of Physicians, Edinburgh, in 1877. He was President of the Royal College of Surgeons, Edinburgh, in 1892, while he had also been President of the Royal Medical Society of Edinburgh, of which he was a member. Dr. Blair-Cunynghame was also a Fellow of the Royal Society of Edinburgh, and a member of several learned Societies in the Scottish capital.

Mount Vernon Hospital for Consumption.

DR. ARTHUR NEWSHOLME will deliver the Inaugural Address in connection with the Post-Graduate Lectures and Demonstrations at the Mount Vernon Hospital for Consumption and Diseases of the Chest, 7 Fitzroy Square, W., to-morrow (Thursday), at 5 p.m. The subject will be "Public Preventive Measures against Tuberculosis in Relation to the Medical Practitioner."

Literary Notes and Gossip.

THE *Sketch* in its current number has an illustrated article on New York's floating hospital for "slum" children, "Number One."

* * *

THE *Builder* for December has an interesting leader on "The Sanatorium Question," in which our point is emphasised that "as sanatoria are being built all over England, it is essential that the greatest care should be exercised in planning them on the most economical and effective lines."

* * *

WE are informed that both his Majesty the King and his Royal Highness the Duke of Connaught have been graciously pleased to accept copies of Captain St. Leger's "War Sketches in Colour," just published by Messrs. Adam and Charles Black.

* * *

THE list of medical men who have tried their hands at novel-writing is now of considerable length. The latest recruit is Major Greenwood, M.D., LL.B., who is announced as having a novel in hand. His book "The Law Relating to the Poor-law Medical Service" is now being advertised in the medical press. Messrs. Bailliere, Tindall and Cox are the publishers of it.

* * *

A VERY interesting historical MS. catalogue has been presented to the Library of Owens College by Mr. J. Joseph Jordan. It is the catalogue of the anatomical preparations in the museum of the Mount Street School of Medicine belonging to Joseph Jordan. Many of the specimens were mounted by his nephew, James Stephens. The number of specimens carefully described and catalogued is over 1,000. It is evident that even in the early days of medical studies in Manchester the Mount Street School was exceptionally well provided with museum specimens. Many of these are now in the Anatomical Museum of Owens College.

* * *

DR. ERNEST GRAHAM LITTLE'S article on "Health Resorts of South Africa" and Mr. Creswicke's "South Africa and its Future" are both peculiarly opportune at the present moment, and may be consulted by medical men with advantage.

* * *

THE forthcoming number of the *British Journal of Inebriety*, edited by Dr. T. N. Kelynack, the hon. secretary of the Society for the Study of Inebriety, will contain *in extenso* Professor G. Sims Woodhead's Lees and Raper Memorial Lecture on "Recent Researches on the Action of Alcohol in Health and Sickness."

* * *

THE *Ophthalmoscope* is one of the new special medical journals, of which this country now possesses a fair number, although by no means so well provided as Germany, the United States, and other foreign countries. Under the able editorship of Mr. Sydney Stephenson, the well known ophthalmic surgeon, the newcomer promises to become a veteran, at any rate, if careful editing can ensure success. A special feature of the *Ophthalmoscope* is the "Notes and Echoes," which give a delightful summary of current events of interest in the ophthalmic world. They are evidently written *currente calamo* by a pen of literary merit, although here and there we note a sign of haste. That drawback, however, seems inseparable from almost all forms of journalism nowadays.

* * *

THE two following paragraphs are culled from the *Ophthalmoscope*:—The limitations of modern surgery are well illustrated by the position of affairs with regard to so common and so disastrous a malady as trachoma. In spite of the enormous amount of painstaking research that has been bestowed upon that disease of recent years, it can hardly be said that we are any nearer the ultimate pathology of that particular morbid process than we were a generation ago. The main advances have been in prevention, and perhaps the greatest stride ahead is the striking and interesting fact that "granular lids" can be cured by exposure to focus-tubes—*alias* X-ray treatment—and to a "high frequency" brush discharge.

* * *

HERE in the United Kingdom the virtue of the scientific investigator is for the most part his sole reward. They manage that sort of thing better abroad—at least, so we gather from a recent official announcement by the Hungarian Minister of the Interior, of a prize of 100,000 marks for the best essay upon the pathology and treatment of trachoma. To be successful essays must show a tangible advance along one of the two indicated lines. The prize may be divided. Essays, which may be in any language, must be sent in by the end of 1904. A step of this kind might well be imitated by His Majesty's Government. Let us say, under the patronage of King Edward VII., half a dozen prizes of £2,000 each were offered for the best essays on scarlatina, comparative tuberculosis, trachoma, malignant tumour, rheumatism, and measles, would there not be a field of possibilities opened up of untold value to our fellow-countrymen of the present and of future generations, not to mention mankind at large?

* * *

AMONG the note-books and diaries that come round each year with Christmastide we may especially mention Messrs. Scott and Bowne's as being a neat and handy little volume for the waistcoat pocket. Our old friends, Messrs. Burroughs and Wellcome, are as usual to the front with a thoroughly up-to-date visiting list for general practice, and an appointment book for consultants. The amount of information condensed in the literary matter of these volumes is simply astonishing and does credit to the compilers. *Knowledge* sends a handsome crown octavo "Diary and Scientific Handbook for 1904." It contains a blank sheet for every day in the year, with the usual tables for accounts, and so on, and is prefaced by a number of valuable scientific articles. It is handsomely bound, and admirably fitted for the library table. It is well worth the three shillings at which it is sold.

* * *

A NEW and seemingly valuable prophylactic addition to the equipment of a fireman has been introduced and is illustrated in the current number of *The Tatler*. It is a protective water spray which completely envelopes the operator. With nippers on his nose, special smoke glasses for the eyes, an oxygen bag supplying the mouth, and a surrounding spray of water effective advance has been made towards successful fighting of the flames.

* * *

THE *Illustrated London News* in its last issue furnishes amusing illustrations of Dr. Lauterwasser's method of dealing with consumption by burying patients in shallow "graves," and sleeping out of doors on the grass. Even the "hut system" is to be superseded. The craze for novelty in the treatment of tuberculosis seems to justify any extravagance.

* * *

"PROPOSED Sterilisation of Certain Mental and Physical Degenerates" is the title of a work by Dr. R. R. Rentoul, which is being published by the Walter Scott Publishing Co., Newcastle and London.

* * *

A VALUABLE study of the so-called "plague" which devastated the metropolis in the seventeenth century appears in Sir Walter Besant's posthumous work, "London in the Time of the Stuarts," which Messrs. Adam and Charles Black have just issued.

The New Course of Post-Graduate Lectures.

THE new course of Post-Graduate lectures of the Mount Vernon Hospital for Consumption and Diseases of the Chest, 7, Fitzroy Square, W., will be opened by an address by Dr. Arthur Newsholme, on "Public Preventive Measures against Tuberculosis in Relation to the Medical Practitioner." The meeting is open to all interested in the subject, and the lecture and demonstrations are free to all medical practitioners and students of medicine.

Laboratory Notes.

"TABLOID" HYDRARGYRI PERCHLORIDI GR. 1-32, ET POTASSII IODIDI, GR. 2½.

MESSRS. BURROUGHS AND WELLCOME have added to their list of "tabloids" one that will be found especially convenient. As everyone knows, in cases requiring treatment by mercury perchloride and potassium iodide, it is usually necessary to continue the administration of the combination with regularity for some time. "Tabloid" Hydrarg. Perchlor. gr. 1-32 et Potassii Iodidi, gr. 2½ has therefore been introduced to provide a trustworthy means of carrying out the treatment when small doses are required. When larger doses are necessary, "Tabloid" Hydrarg. Perchlor. gr. 1-16 et Potassii Iodidi, gr. 5, which has been issued for some time past, may be prescribed.

FRY'S COCOA AND MILK.

THIS preparation by J. S. Fry and Sons, Bristol, is a highly nutritious compound of cocoa and sweetened milk, and forms a very convenient and concentrated food. It is free from the least trace of rancidity and after it had been kept open for a considerable time in the laboratory, we found that it had not undergone any decomposition whatever.

On analysis we have obtained the following results:

Moisture, 22.0;
Mineral matter, 2.0;
Albuminoids, 10.0;
Fat, 12.0;
Sugar, by difference, 54.0.

A careful search for poisonous metals proved their entire absence.

From these results it is plain that this preparation is a highly concentrated food of great value, which keeps well even when the tin has been open for a considerable length of time.

Medical News.

The New Appointments at Dr. Steevens' Hospital.

THE Board of Dr. Steevens' Hospital met on December 22nd, to fill the posts of visiting physician, gynæcologist, and house surgeon. The physiciancy was vacant owing to the regretted resignation of Dr. Henry C. Tweedy, due to ill-health. Dr. Tweedy had been connected with the hospital for many years, and his resignation was deeply regretted. The gynæcologistship was vacant by the election of Dr. Hastings Tweedy to the Mastership of the Rotunda Hospital, an appointment to which we have already referred in these columns. The election resulted in the appointment of Dr. T. P. C. Kirkpatrick, Assistant Physician to the post of physician; and of Dr. Henry Jellett, a former assistant master of the Rotunda Hospital, to the post of gynæcologist; and of Dr. Blackley to the post of house surgeon. At the same meeting Mr. R. L. Swan, F.R.C.S. was co-opted a Governor of the Hospital.

Epileptic Colony.

THE Asylums Committee of the London County Council recently reported that the epileptic colony on the Horton Estate, Epsom, provided accommodation for 266 male and 58 female patients. They had transferred from the other asylums all the male epileptics who were suitable cases for the colony and had a few vacancies remaining. These they proposed to use for the reception of private male patients, their experience in regard to the private accommodation elsewhere having convinced them that a moderate charge was much appreciated by a class of people who were unable to pay the high charges of private institutions. The rates to be charged would be 18s. 1d. and 21s. a week.

Death under Ether.

A MANCHESTER soldier, Francis Taylor, of Pollard Street, Ancoats, has died while under the influence of an anæsthetic, administered for the purpose of an operation. When he arrived home on furlough recently he was suffering from a swelling in the neck, apparently caused by a bad tooth. On the 17th inst. a doctor was called in, who found Taylor in a serious condition. It was necessary to do something at once, and ether was administered. At first the deceased man took the ether badly, but soon afterwards he quietened down. It was then thought advisable to draw a tooth, but before the instrument could be got into his mouth his breathing suddenly stopped. The Coroner's jury agreed that death was due to misadventure.

Memorial to the late Dr. John Manley.

ON December 18th a marble bust of the late Dr. John Manley, formerly medical officer for the borough of West Bromwich, and chairman of the Free Library Committee, which has been placed in the central reading room, High Street, as a permanent memorial of the services rendered to the town by him, was unveiled in the presence of a numerous company by Alderman H. Hartland, who, on behalf of the subscribers, handed it over to Councillor A. G. Furley (Mayor). Underneath the bust is the following inscription: "John Manley, Esq., J.P., member of the Free Library Committee from 1875 to 1902, and chairman of the above 1891 to 1902; 17 years medical officer of health for West Bromwich. A tribute of admiration and respect from a number of his personal friends. Born 1827, died January, 1902." The cost of the bust, which is the work of Mr. Hopkins, of West Bromwich School of Art, has been defrayed by subscriptions.

London School of Tropical Medicine.

OF the students of the above school who presented themselves for the examination at the end of the October-December, 1903, Session, the following have passed:—Dr. A. E. Horn (Colonial Service), Dr. A. H. Barclay (Foreign Office), Major Wilson, (R.A.M.C.), M.B., &c., Dr. W. J. Radford (Foreign Office), passed with distinction; Dr. D. Cowin (Colonial Service), Dr. J. E. Mitchell, Dr. S. G. Ranaday, Dr. C. H. Allan (Colonial Service), Dr. J. T. Cartaya, Dr. F. A. Baldwin (Colonial Service), Dr. T. F. G. Mayer (Colonial Service), Dr. F. C. Sutherland, and Dr. Guy Ruata.

More Small-pox in London.

IT was reported to the Public Health Committee of the Stepney Borough Council last Friday, that three cases of small-pox had broken out in Mile End since Christmas Day. Every precaution was being taken to prevent the spread of the disease. Mile End being so notoriously anti-vaccinationist a district, the occurrence there of small-pox is of more than ordinary significance.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Medical Sickness, Annuity and Life Assurance Society was held at 429, Strand, W.C., on December 18th. There were present Dr. de Havilland Hall (in the chair), Dr. St. Clair B. Shadwell, Mr. J. Brindley James, Dr. Fredk. S. Palmer, Dr. M. Greenwood, Dr. J. W. Hunt, Mr. H. P. Symonds, Mr. F. S. Edwards, Dr. F. J. Allan, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The accounts for the eleven months, ending in November last, show tnat the Society had in that period secured more new members than in the previous twelve months, and it seems clear from the steady increase in the number of applicants for membership that the advantages which the Society offers to members of the profession are becoming more widely known. The amount paid away in Sickness claims is less than in the corresponding period of last year, and there is every reason to hope that the result of the quinquennial valuation of the Society's business, now in progress, will show that an ample margin exists after providing for all liabilities. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial* and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

APPRECIATION.

A Subscriber at Sheffield in remitting his annual subscription this week writes:—"I always enjoy reading your journal in my brougham; it is not too big nor overloaded with a lot of theoretical rubbish. I greatly appreciate its crisp style."

A Glasgow correspondent writes by same post:—"I like your journal so much that I introduced it to my friend Dr.——, who said he would like to become a subscriber."

Such messages of appreciation are greatly esteemed and help to lubricate the wheels of medical journalism, preventing them from clogging.

N. T. B, Y.—Our correspondent is thanked for his suggestion, which shall be acted upon.

EXCELSIOR.—From inquiries which we have made into the matter, our answer must be in the negative.

WESTERN.—Yes.

SANATORIUMS OR SANATORIA.

MUCH difference of opinion exists as to the proper plural of the word sanatorium, some preferring a frankly English plural—sanatoriums—others voting for sanatoria. Since the word is of Latin extraction it may not be without interest to know that the secretary of the French Academy, the great authority in the matter of orthography, has decided in favour of the former, he having discovered a number of French words terminating in 'um' which form their plural by the addition of an 's.' Possibly this decision may assist us in deciding which form to adopt.

F.R.C.S.EDIN., writes:—"Can any one of your readers give me some information as to the prospects of starting general practice in Western Australia? Where could I find a description of the climate, and other details of the Colony?"

EMOLUMENT.

A Board-School girl, asked to define the term emolument, described it as "A soothing medicine"—nor, *pace*, the professor of materia medica, was she very wide of the mark.

W. B. R.—The so-called "acrodynic erythema," a term applied to the patchy red spots you describe on your patient's palms and soles is now usually ascribed to a toxic action on the ocrd. It is difficult to name any satisfactory therapeutic plan of treatment, but there are two modern methods, namely, hot-air baths and "high frequency" electrical currents, which certainly would be worthy of trial. Drugs have little influence upon the condition.

Dr. WALLWOOD.—No "characteristic organism of cancer" has yet been isolated. The bacteriology of cancer, so far, has proved negative

DR. AMRIK SINGH (Lafurwal) is thanked for his communication, which is reserved for future reference.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 6TH

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. R. H. Bell and Mr. J. D. Malcolm. Short Communications—Dr. V. Bonney—Pyometra in One Half of a Septate Uterus.—Dr. A. W. W. Lea—Abscess of the Uterus. Paper—Dr. H. R. Spencer—Fibro-myoma of the Intra-abdominal Portion of the Round Ligament of the Uterus.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. P. J. Freyer—Clinique. (Surgical.)

THURSDAY, JANUARY 7TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson. Clinique. (Surgical.)

FRIDAY, JANUARY 8TH.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9 Adelphi Terrace, Strand, W.C.).—7.30 p.m. Council Meeting. Paper—Dr. J. Spottiswoode-Cameron—The Sophistication of Foods.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.). -8.30 p.m Papers—Sir Dyce Duckworth and Prof. H. Marsh—A Case of Pneumococcal Peritonitis—Dr. F. Taylor—A Case of Pneumococcal Peritonitis.—Dr. S. Phillips—A Case of Fibroid Disease of the Pancreas with Calculi, accompanied by Jaundice and subsequently by Diabetes, Laparotomy, Relief of Symptoms, Death.

ROYAL ACADEMY OF MEDICINE IN IRELAND. Section of Obstetrics. Papers—Dr. Purefoy—Report of the Rotunda Hospital for the year 1902-03. Drs. Jellett and Earl—Sarcoma of the Vagina with notes on a case. Exhibits by card.—Dr. W. J. Smyly—Papillomatous ovaries.—The President 1. Pyo-salpinx (four specimens). 2. Large Intra-ligamentous Fibro-myoma. 3. Interesting Ovarian Cysts.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. A. Lawson—Clinique. (Eye.)

THURSDAY, JANUARY 14th.

At 20]Hanover Square, W., at 8 p.m. A paper will be read by Dr. Mendes de Leon, on "A hitherto not sufficiently recognised source of infection during operations." The President will deliver his Valedictory Address.

Appointments.

BUSH, JAMES PAUL, M.R.C.S., L.S.A., C.M.Glasg., Medical Officer to the Bristol Post-Office.

CORFIELD, CHARLES, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Bristol Dispensary.

FOLKER, H. H., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Hanley District of the county of Stafford.

GILFORD, SIDNEY, M.B., Ch.B.Edin., House Surgeon to the Paddington Green Children's Hospital.

HOLLAND, EARDLEY, M.R.C.S., L.R.C.P.Lond., House Physician to the Paddington Green Children's Hospital.

HOUSEMAN, EDWARD A., B.A., M.B., B.C.Cantab., Medical Officer to the East Indian Railway.

ISHERWOOD, F., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory Act for the Cockermouth District of the county of Cumberland.

LAMPORT, ETHEL FRANCES, M.D.Brux., L.S.A., Public Vaccinator for the Isle of Dogs district of Poplar.

MCNABB, H. HORSMAN, M.D.Vict., Assistant Honorary Surgeon to the Manchester Royal Eye Hospital.

MOORE, LEONARD A., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Bristol Dispensary.

STANLEY, JOHN DOUGLAS, M.D.Edin., M.R.C.P.Lond., Honorary Physician to the Birmingham Children's Hospital.

THOMPSON, WILLIAM FOOKES M.D., C.M.Edin., Medical Officer for the Northpetherwin District by the Launceston (Cornwall) Board of Guardians.

TURNER, H. N., M.B., B.S.Glasg., Certifying Surgeon under the Factory Act for the Castle Bytham District of the county of Lincoln.

WADE, HENRY, M.B., F.R.C.S.Edin., Conservator of the Museum of the Royal College of Surgeons, Edinburgh.

WALKER, J. D., M.B., M.S.Aberd., Certifying Surgeon under the Factory Act for the Shaftesbury District of the county of Dorset.

WILLIAMS, S. R., M.R.C.S., L.R.C.P., Clinical Assistant at the Chelsea Hospital for Women.

Vacancies.

Ancoats Hospital, Manchester.—Resident House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

City of London Lying-in Hospital, City Road, E.C.—Surgeon-Accoucheur. Salary £100 per annum. Applications to R. A. Owthwaite, Secretary.

Department of Medicine, Yorkshire College, Leeds.—Junior Demonstrator of Pathology. Salary £120 per annum. Applications to the Registrar.

Metropolitan Asylums Board.—Male Assistant Medical Officer. Salary £150 per annum, with rations, lodgings, attendance, and washing. Applications to the office of the Board, Embankment, E.C.

Royal Victoria Hospital, Bournemouth.—House Surgeon. Salary £110 per annum, with board and lodging. Applications to the Chairman of Committee.

St. Mary's Hospital Medical School, Paddington, W.—Demonstrator of Physiology. Salary £150 per annum. Applications to H. A. Caley, M.D., F.R.C.P., Dean.

Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £50 per annum, with board, lodging, and washing. Applications to the House Surgeon.

Tiverton, Devonshire, Infirmary and Dispensary.—House Surgeon and Dispenser. Salary £80 per annum, and all found. Applications to Arthur Fisher, Hon. Secretary.

Wolverhampton Eye Infirmary.—House Surgeon. Salary £70 per annum, with rooms, board, and washing. Applications to the Secretary.

Births.

EDMONDS.—On Dec. 28th, at Manor House, Inverleith Avenue, Streatham, S.W., the wife of C. J. Ernest Edmonds, L.R.C.P.Lond., M.R.C.S.Eng., of a daughter.

HARNEIS.—On Dec. 31st, at 186 Amhurst Road, the wife of T. W. Morcom Harneis, M.R.C.S., L.R.C.P., of a son.

JELLETT.—On Jan. 3rd, at 61 Lower Mount Street, Dublin, the wife of Henry Jellett, M.D., of a daughter.

Deaths.

BARTELS.—On Dec. 21st, at West Kensington, of acute bronchitis, Dr. Bartels, formerly of Cambridge and Clapham, aged 83.

ELLIOTT.—On Dec. 23rd, at 115 Ladbroke Grove, W., Mary Christian Elliott, widow of the late Captain John Bardoe Bowes Elliott, J.P., and daughter of the late Dr. James Corbet, J.P., aged 69.

HUNTER.—On Dec. 28th, at 146 Lavender Hill, Frederick Hunter, M.R.C.S., L.R.C.P., &c., the loving and beloved husband of Caroline Ida Hunter.

SUGDEN.—On Dec. 30th, at Buckfastleigh S. Devon, D'Arcy Sugden, M.R.C.S Eng., L.R.C.P.Lond., third son of the late William Sugden, of Bath.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

Original Communications.

THE HYGIENIC TREATMENT OF CONSUMPTION. (a)

By T. N. KELYNACK, M.D., M.R.C.P.,

Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood, London.

A RATIONAL conduct of the hygienic treatment of consumption must be based on a sound knowledge of the pathology of the affection and wide experience of its most varied symptomatology.

There seems a danger, at least in some quarters, of assuming that in the so-called "open-air" method we have discovered a "specific" treatment of consumption which, irrespective of accurate information regarding its pathology or satisfactory interpretation of clinical manifestations, may nevertheless secure arrest of the disease and perfect restoration to health.

It is most necessary that every effort should be made to prevent discredit being brought upon a system which offers the best-known means of satisfactorily coping with pulmonary tuberculosis.

The two chief principles underlying the hygienic management of consumptives are :—

1. The removal of the patient from the sphere of action of the causal influences of the disease.

2. The establishment of such conditions as will allow of the development of reparative processes and the evolution of the highest powers of resistance.

And to this end experience and experiment have abundantly testified that the following factors are of great importance :—1. A continuous open-air life under natural conditions. 2. Free exposure to sunlight. 3. Carefully regulated rest. 4. Graduated exercise. 5. Abundant dietary. 6. Strict compliance with all hygienic requirements. 7. Constant medical supervision.

THE EVOLUTION OF TUBERCULOSIS.

Before passing to consider the various ways in which the hygienic treatment of consumption is being carried on, particularly in this country at the present time, it may be desirable to consider for a moment the conditions which have led to the invasion of the human by the tubercle bacillus.

It would be as useless to romance as to the manner in which the first primitive man fell a victim to the attacking microbe as to attempt an explanation of the origin of this human parasite, but from a study of such glimpses of the life of prehistoric man as have been revealed by much patient and painstaking research we may at all events gain some idea of the slow development of environmental influences and the evolution of actual tissue conditions which have rendered man peculiarly prone to tuberculous invasion. It seems very probable that among civilised people under conditions such, for instance, as exist in this country and America that half the community have or have had some form of tuberculosis. (a)

Post-mortem investigations certainly clearly show that something like 30 per cent. of individuals present evidences of having been the subjects of a tuberculous infection. (b)

Primitive people, as far as can be ascertained, when living a free and nomadic life show but little susceptibility to tuberculosis. Wild animals rarely suffer. And even certain animals which are experimentally susceptible to tuberculosis only exceptionally contract it spontaneously.

On the other hand, natives subjected to so-called influences of civilisation are peculiarly prone to develop phthisis, and oftentimes show but feeble powers of resistance to a tuberculous invasion.

Domesticated animals, as is well known, manifest marked susceptibility. Captive monkeys are frequently affected, and the disease is widespread among cattle and fowl, and is met with also in pigs, dogs, cats, horses and sometimes sheep.

Primitive man, as far as we can ascertain, enjoyed with the free living animals a high degree of resistance to tuberculosis.

There is reason to believe that at least in most European countries the progress of Western civilisation has been accompanied until recent times by an increase in consumption. It is well to remember that the Greeks and Romans and Arabs practised the hygienic life to a greater extent than is possible for most of us at the present time, for they both by day and night were probably exposed to a more abundant supply of fresh air than is now possible in our country with its crowded cities and densely populated districts.

It is neither possible nor desirable to return to the habits and customs of primitive man, but it is at least reasonable to inquire if in the process of civilisation we have not departed from desirable, natural, and health-maintaining procedures.

Primitive man was no doubt much of a vagabond, but he was at all events mainly engaged in pursuits necessitating an open-air existence. He was freely exposed to the beneficial influences of sunlight and other natural forces. His exercise and rest were directed and governed chiefly by the exigencies of creative needs. He had to work for his food. It is certain he did not allow his sanitary requirements to be arranged by an unknown medical officer of health, neither did he consult his physician on the desirability of fashioning his life in accordance with hygienic principles.

I do not wish to be misunderstood. I do not advocate a return to barbarism, but we must all recognise, I think, in studying such a disease as consumption, the necessity of availing ourselves of the light which the teaching of evolution is capable of affording.

To sum up, therefore, we may say—Most healthy individuals possess vigorous powers of resistance to tuberculosis. The maintenance of a high standard of personal hygiene affords the best security

(a) Portion of a Lecture delivered in connection with the Post-Graduate Lectures in the Central Out-Patient Department of Mount Vernon Hospital, Fitzroy Square, London.

(a) Consult "Tuberculosis." By Norman Bridge, A.M., M.D. London, &c., 1903.

(b) Ransome, A., "Bodily Conditions Resisting Phthisis." *Medical Chronicle*, April, 1903.

against infection. The protective agencies of the body are manifold, but their efficiency can only be secured by systematic compliance with natural law. We do not, of course, deny the immense importance of an inherited or acquired susceptibility, but probably we are not going too far in suggesting that the perfectly healthy individual enjoys an almost absolute immunity to tuberculosis.

DETAILS OF SANATORIUM TREATMENT.

It is now generally admitted that the hygienic treatment of pulmonary tuberculosis can be most effectively carried out in a specially designed and definitely conducted institution. Hence the term "hygienic treatment" may well be replaced by the title of "sanatorium management," but unfortunately it is necessary to say the latter does not always altogether include the former.

I have recently visited a number of excellent sanatoria, and have been much struck by the wide differences in methods and procedures. Considerable divergence in practice exists, and great variation in the conduct of all important details is everywhere conspicuous. No doubt at a time when much in regard to so-called sanatorium treatment is in an experimental stage, a certain variety in practice is not only permissible, but even desirable, but it is of the greatest importance that in this very special line of medical work an open mind should be maintained, and a strict scientific spirit upheld, and all faddist and quackish narrowing of outlook avoided.

Almost of necessity most physicians engaged in sanatorium practice are more or less isolated, and to a great extent deprived of contact with medical centres. It seems to be most desirable that public sanatoria, at least, should not be left to the sole care and discretion of resident officers, but should always be furnished with a visiting staff. At the present time, when sanatoria are springing up all over the country, it would be well if some means could be found whereby greater co-operation and combination in scientific work, and comparison of clinical procedures and results, could be secured. A study of the reports of the various British sanatoria will furnish abundant evidence of the need for some such combine. (*a*)

In the carrying out of an effectual hygienic treatment of consumption among the poor, I believe some such comprehensive scheme as we are endeavouring to provide in the case of Mount Vernon Hospital is absolutely necessary.

1. A central out-patient department for the selection of suitable cases for admission to the hospital and sanatorium, the treatment of patients who cannot obtain admission to any suitable institution, and the periodical inspection of those who, having undergone sanatorium treatment, have returned home or recommenced work.

2. A hospital maintained on sanatorium lines, near the city, where acute cases may be readily admitted, and doubtful ones watched and thoroughly investigated.

3. A country sanatorium, where carefully selected cases may, under strict medical control, careful nursing, and perfect hygienic conditions, be directed to a practical recovery.

It is also very necessary that a suitable home for incurable cases should be included in such a scheme. For children, a special institution, preferably by the sea-side, is desirable. And for many consumptives it must be remembered that return to town life means almost inevitably reinfection or recrudescence of the slumbering disease. For such, a hygienically conducted colony seems the only solution.

In some cities it is possible to render real benefit by providing a home officer who visits bedridden cases and patients who, because of weakness or other disability, are unable to attend the out-patient department. By such service much suffering is relieved and friends can be educated regarding the best means of preventing the propagation of the disease. It is much to be desired that a larger number of nurses, especially those whose duty brings them into contact with the poor, should be trained in the details of the hygienic treatment of consumption.

It is not my purpose to dwell on the most important matter of the selection of cases for hygienic treatment, although the utter insufficiency of sanatorium accommodation for the poor in this country at the present time makes this subject one of pressing importance. I have discussed it elsewhere. (*a*)

Time will not allow me to dwell at length on the various factors in the hygienic treatment as now conducted in the best sanatoria. I can only touch on some of the more conspicuous features.

THE OPEN-AIR LIFE.

Free access to fresh air and sunlight forms the most essential factor. Such can be best attained by securing an out-of-door life. Generally speaking, climate is mainly of importance in so far as it allows of an unrestrained life in the open. Dr. R. W. Philip, as far back as 1898, (*b*) contended that phthisis may be treated with approximately equal success, or want of success, in all climates, according as the larger indications for treatment are fulfilled or overlooked.

Experience has fully justified his statement that, "It is a comforting doctrine, and economically reassuring, that the tuberculous patient of whatever country or race can be suitably treated not far from his own home."

The various reputed climatic factors have been much discussed. (*c*) Doubtless several are of considerable moment, but concisely summarised they are all mainly of importance in so far as they encourage the patient to live the open-air life.

REST AND EXERCISE.

The consideration of arrangements for rest and exercise must not be separated, as is so often the case. The right apportioning forms one of the most difficult and responsible of the duties of a medical man directing the hygienic treatment of a consumptive.

We are all acquainted with Hilton's wonderful classic on "The Therapeutic Influence of Rest, and the Diagnostic Value of Pain," and although much of its application is directed to surgical work, the principles there laid down are almost equally serviceable in the practice of medicine, and have particular bearing on the management of consumptives. Almost every case of pulmonary tuberculosis, at least until carefully studied in all its bearings, should be submitted to rest. It is a general rule, and I think a very good one in most institutions, to keep the patient altogether in bed for the first few days. Rest is not only valuable as a means of conserving energy, but also because it is capable of exercising a beneficial psychological action. Absolute rest in the recumbent position is of the utmost importance for all acute cases, for it gives the greatest possible measure of immobility to the thoracic wall over the affected portions of the lungs. Abundant sleep, it must be remembered, is one of the most natural means of securing perfect rest to mind and body.

But while local and general rest play an important part in securing the establishment of reparative processes, and when wisely directed go far to restore mental force and bodily vigour, I am convinced that judiciously selected and wisely applied exercise stands in the very forefront of natural agencies which may assist greatly in conducting many consumptives back to healthy life.

All exercise should only be undertaken under strict medical direction. Much harm is undoubtedly done by the unregulated wandering of patients in an early stage of the disease. The uncontrolled exercise indulged in by many incipient cases sent to convalescent homes not infrequently seriously aggravates the condition. The temperature is a valuable guide in con-

(*a*) See Series of Special Articles on "British Sanatoria for Consumption," THE MEDICAL PRESS AND CIRCULAR, July 8th 1903, *et. seq.*

sidering the qualitative and quantitative features of exercise.

Probably the safest, surest, and most scientific form of exercise for the convalescing consumptive is regulated walking.

The length, speed, and character of the walk must be carefully graduated by the physician, who must make a thorough individual study of each case. By carefully graduated walks much may be accomplished in the way of thoracic expansion.

Various forms of respiratory exercises have been advocated, but much judgment is necessary to avoid undesirable or actually prejudicial results unless the exercises be always conducted under medical supervision.

HYDROTHERAPEUTIC MEASURES.

Most jaded and weary workers have experienced the bracing and revivifying effects of a cold dip or tepid bath.

I need not stay to remind you of the physiological action of hydrotherapeutic measures on the cardio-vascular apparatus and cutaneous functions.

But what is undoubtedly one of the most useful hygienic measures in health should not be discarded in such a pathological state as pulmonary tuberculosis. Of course, the form of bathing must be made to fit the case.

In some of the newer sanatoria elaborate arrangements have been made for various forms of spray and douche baths.

I believe a judicious application of hydrotherapeutic measures is likely to prove of much benefit in the management of phthisical cases.

Electric baths are useful mainly for their general tonic action.

DIETARY.

Wide differences of opinion still exist in regard to the number of the meals, character of the food, and manner of its preparation and presentation, best suited to the needs of the consumptive.

In this country forced feeding is fortunately not carried out in such drastic fashion as has been tolerated abroad. It is, however, necessary that the diet should be abundant and highly nutritious.

In some sanatoria in this country the medical officer personally superintends the distribution of all food. The food given is in some institutions carefully weighed and all partaken of charted.

It must be remembered that mere increase in weight alone is not necessarily a favourable indication.

In not a few instances where rapid addition to the bodily weight is made, it is speedily lost on the patient leaving the sanatorium.

Much of the difficulty of adequately dealing with many of the cases which attend as out-patients arises from the fact that they are insufficiently or improperly fed.

In some towns and cities the plan followed by the Edinburgh Victoria Hospital might well be adopted. "Visitant" patients are admitted as "day boarders," and enjoy the *régime*, dietary, and other benefits of the institution throughout the day, returning home to sleep. Some such arrangement might go far to minimise the suffering now resulting from the enormous pressure on some sanatoria, where cases have frequently to wait for five or six months before admission is possible.

THE INSUFFICIENCY OF SANATORIA FOR THE CONSUMPTIVE.

Much difficulty is now being experienced in providing means for the application of efficient hygienic measures in the treatment of the consumptive poor. It has been recently estimated by Dr. Shirley Murphy that in the administrative County of London over 7,500 persons die from phthisis annually; and Dr. Alfred Hillier has calculated that the hospital and infirmary expenditure for consumptive patients in London alone probably exceeds £100,000 a year.

The common but pernicious system which prevails of requiring an introduction by a subscriber's letter is little short of inhuman and altogether unscientific.

The insufficiency of sanatoria makes it necessary to keep patients seeking aid and yet requiring immediate attention waiting for five months or more, which means that valuable time and strength are lost just at that period when the greatest assistance might be rendered.

The case of the indigent consumptive was probably never more pitiable. High hopes for relief are being raised only too frequently to be quenched by the unfortunate condition of circumstances which might and should be altered.

It is not for me to enter now into a discussion on this very wide and difficult question of ways and means for the adequate provision of hygienic necessities for the treatment of the consumptive poor. It is, however, becoming abundantly clear that collective public action must be taken, for only by securing efficient treatment of the indigent consumptive can we hope to secure means for protecting all sorts and conditions of men and women from joining the ranks of the tuberculous sufferers.

The revelation of the gospel of hygiene has pointed out a way whereby many of the ills to which it was supposed flesh was heir may be escaped; and medical science has now conclusively shown that such hygienic measures may also furnish means for the arrest of disease, and, at least for the consumptive, a means of relief has been secured in what we are now accustomed to term sanatorium treatment. It only remains for us to apply our knowledge in accordance with the principles of scientific medicine and the dictates of a sound common sense.

NOTES ON A CASE OF PERFORATION IN TYPHOID FEVER.

By HENRY C. DRURY, M.D., F.R.C.P.I.,

Physician to Sir Patrick Dun's Hospital, Visiting Physician to Cork Street Fever Hospital, &c.,

AND

WILLIAM TAYLOR, M.B., F.R.C.S.I.,

Surgeon to the Meath Hospital and Co. Dublin Infirmary; Surgeon to Cork Street Fever Hospital, &c.

J. H., æt. 21, was admitted to Cork Street Fever Hospital on August 4th, 1903. He was an ambulatory case of typhoid fever, and, in consequence, we were unable to find out how long he had been ill, but from his own account we considered it was about his twelfth day of fever. In reality he had probably been ill three weeks or more.

He appeared to be quite a mild case, and when seen the morning after admission presented absolutely no bad symptom. Though a thin, spare subject his aspect was good. The abdomen was flat, the tongue moist and not very dirty. There were a few rhonchi in the lungs, the heart was sound, the bowels moving moderately, and the appearance of the motions satisfactory. His temperature was moderate, varying between 101·2° and 101·8° morning to evening; the pulse quiet, between 84 and 96. There was, therefore, no cause for alarm in his condition. However, the next morning—the second after admission—at 7.45 a.m., he complained of a severe pain in the abdomen. Dr. Sandes, one of the assistant resident medical officers of the hospital, saw him; the pulse was then quiet. I must acknowledge the splendid way in which Dr. Sandes looked after and managed the case throughout, for as the resident medical officer was away for his holidays, Dr. Sandes had the entire responsibility. At 9 o'clock, pain continuing and increasing, he was given ¼ gr. morphia hypodermically; the pulse was still quiet—under 100. At about 12 o'clock, when I saw him, it had risen to 120; he had a drawn, anxious look, the abdomen was full and slightly distended; it was very tender on pressure, tympanitic, but liver dulness present. It was apparent that perforation had taken place, and Mr. Wm. Taylor, the surgeon to the hospital, was asked to

intervene. By the time Mr. Taylor could be got, and was able to be at the hospital, it was 3.30 o'clock. Everything being in readiness, the operation was commenced, seven and a half hours after the occurrence of perforation, but by this time the patient's condition had greatly changed for the worse, and the pulse-rate had risen to 150 or over.

MR. TAYLOR'S ACCOUNT OF THE OPERATION.

When seen by me at 3.30 p.m. the condition was most unpromising. The pulse was 150 to the minute; small, thready and irregular. The facies was typical of a peritoneal catastrophe. The respirations were over fifty a minute. The abdomen was distended, motionless, rigid and tender all over. Though his condition was most unfavourable for operation, I considered myself morally bound to give him whatever chance surgery offered. The skin of the abdomen was quickly cleansed and the abdomen freely opened, under light ether anæsthesia, through the right rectus muscle. The intestines were allowed to prolapse into warm towels. The perforation, which was a small one, was easily found about fifteen to twenty inches from the ilio-cæcal junction. The opening was closed by enfolding it with a purse-string suture, over which a continuous Lembert suture of fine silk was placed. A second ulcer which seemed just about to perforate, some twelve or fourteen inches higher up, was also enfolded with a purse-string suture. While I was dealing with the intestine, my assistant, Dr. Sandes, was washing out the abdominal cavity with warm saline solution. Having then got the intestines free of the septic fibrin with which they were covered, and the general peritoneal cavity as thoroughly cleaned as the condition of the patient permitted, the intestines were returned, and the edges of the wound approximated by through-and-through sutures of silkworm-gut. Several pints of warm saline solution were left in the abdominal cavity. The operation from start to finish occupied about twenty-one minutes, and the patient was returned to bed with a pulse of much the same rate as before we started.

DR. DRURY'S ACCOUNT CONTINUED.

Subsequently, great interest attaches to the struggle to keep the patient alive, and the very highest credit is due to Dr Sandes and the nurses, by whose unremitting attention, day and night, success in this endeavour was attained. The measures used were nutrient enemata, saline enemata, hypodermic injections of morphia, strychnine and digitalin. The heart, which was flickering at the rate of 150, was thus kept going, and by the fourth day after the operation it had gradually strengthened in force and diminished in frequency to 100.

Owing to his enfeebled and febrile condition, together with the effect of the ether administered for anæsthesia, the lungs became greatly filled up with bronchitic fluid, and there were moist *râles* all over the chest. It was therefore necessary, in spite of the operation, to keep him constantly moved from one side to the other. His fever still continued at high range, but his general condition steadily though gradually improved. The lungs slowly cleared, the heart became stronger and less frequent in action, and at the end of a week after the operation the temperature reached and remained at normal—*i.e.*, nine days after admission, or seven days after operation.

On the removal of the stitches from the abdominal wound, which had apparently closed all right, it was found there was an abscess in the deeper parts of the incision, due, no doubt, to its infection by the fæcal material which had escaped from the perforated bowel. The whole wound then suppurated and sloughed. By Dr. Sandes' constant attention this was got into a healthy condition and brought together without having infected the general peritoneal cavity. This suppuration was accompanied by a mild fever of hectic type, which came on about a week after the enteric fever had ended, and which lasted for another week. In spite of this, he convalesced steadily, but lest this fever should have any connection with his enteric, we were careful not to take any liberties with his diet, so it was not till this fever had ended—and fifteen days after what we considered as the enteric fever was over—that he was given some solid food in the shape of bread crumb. This agreed well, and very cautiously other additions were made, but nothing stronger than a lightly boiled egg had been given up to the beginning of September. It will be remembered he was admitted on August 4th.

On the evening of September 2nd, twenty-eight days after operation, he complained of pain in the abdomen. Nothing abnormal could be found except some tenderness all over the retracted abdomen. The pulse and temperature remained unchanged, and the bowels had moved twice naturally; there was slight emesis with retching, and the breathing was costal.

The next day pain was still complained of, but nothing fresh was made out, except that the abdomen was slightly fuller, and the bowels had not moved.

On the third day the abdomen was decidedly fuller, there was still dull continuous pain. One drachm of castor oil produced a very small motion, but there was no other relief.

On the fourth day there was still pain, the patient again looked wretchedly ill; the abdomen was manifestly distended. Up to this the pulse and temperature had remained normal, but now, though the temperature still remained normal, the pulse had risen to 116. The bowels had not moved. Mr. Taylor was again asked to see him, and while present an enema was given which was returned unchanged. He at once resolved to open the abdomen again, and endeavour to undo the cause of obstruction.

FURTHER NOTES BY MR. TAYLOR.

Second operation, 4½ weeks after suturing perforations.—When seen by me he presented all the appearance of acute intestinal obstruction. He was then vomiting, and complained of severe spasms of pain; the expression was anxious, the abdomen generally distended, and constipation was then absolute. An enema produced no effect. The abdomen was again opened, when the intestines were found extensively matted to each other and to the abdominal wall. With considerable difficulty, on account of the density of the adhesions, a separation was effected. The obstruction was evidently due to sharp angulation, the result of adhesions, as no distinct band was found producing constriction at any point. Two very distended coils were evacuated of their contents, and the abdominal wound again closed. The time occupied was about forty minutes. Unfortunately the poor fellow never rallied, and sank about ten or twelve hours later.

This most unfortunate result is much to be deplored, for the operation Mr. Taylor performed during the course of the fever was really successful; it prolonged the patient's life for four and a half weeks, and having been undertaken during the course of the fever, such a result is rare.

The post-mortem showed that the obstruction was in no sense due to the sutures in the gut. These completely closed the perforation, and there was no leakage. In fact, the only evidence we could get of the site of perforation was the presence of the silk sutures. Healing over the two sutured areas was perfect. Where precisely the obstruction occurred could not be seen, as the adhesions had been broken down at the second operation. But inside the bowel a most instructive and one of the most important observations from a physician's point of view was made, namely, that there were numerous large ulcers still present—in the processs of healing, it is true, but not by any means healed. They were variable in size, some large and surrounded by a raised margin. A very few appeared to have healed, but the majority were still open. That is, we found open, healing ulcers, more than three weeks after the enteric temperature had reached the normal level; and the appearance of these ulcers was such as to lead us to conclude that it would have required at least another week or fortnight to complete their repair. In other words, the ulcers would not have healed till four or five weeks had elapsed from the termination of the fever.

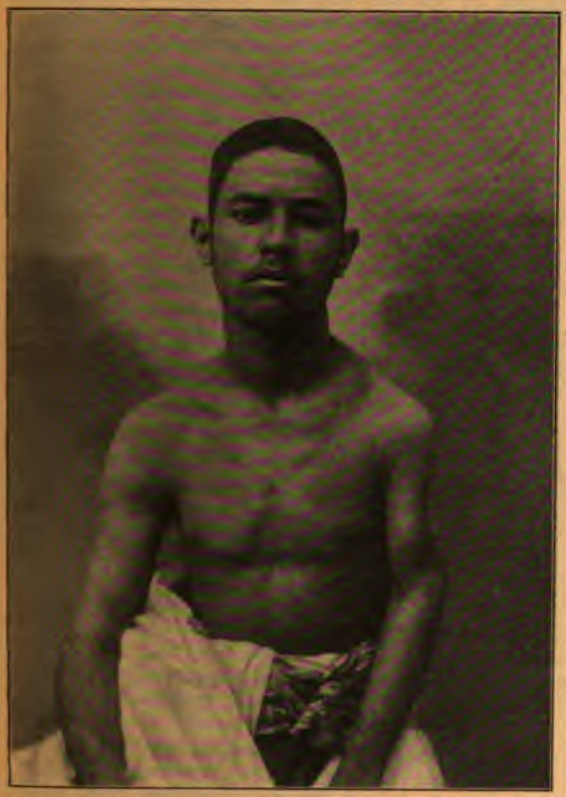
AN UNUSUAL CASE OF
PSEUDARTHROSIS

Under the care of PROFESSOR RAY, M.D.,
Surgeon to the Civil Hospital, Algiers; Professor of Medicine in the University of Algiers.

[SPECIALLY REPORTED FOR THE "MEDICAL PRESS AND CIRCULAR" BY MR. A. CABANES, HOUSE SURGEON.]

THIS case is of some interest in view of the history and the fact of its being a case of infantile pseudarthrosis, this lesion being comparatively rare in childhood, especially in respect of the upper limb.

The patient is an Arab, æt. 18, who was admitted on October 18th, 1903, with the following history:—When two years of age he met with an accident which left him with a fracture of the left humerus. As he was far removed from civilisation the injury was attended to by the tribal bone-setter who fixed



the limb by means of a plate of leather, softened by soaking in oil. This was moulded to the upper arm and reinforced by four wooden splints, which were maintained in position by four bands, twisted tourniquet-fashion. The bone-setter visited the patient twice a week and, as union was delayed, he twisted the apparatus on each occasion, more and more tightly. At the expiration of about two months of this rigorous treatment the skin over the fractured bone became gangrenous. On the outer side of the arm the tissues broke down, creating a solution of continuity through which three fragments of bone were eliminated. The first measured about three inches in length and the two others, one two, and the other one and a half inches, in length.

At this stage the "medicine man" thought it advisable to remove the apparatus, and the wound, which discharged pus freely, ultimately healed in some forty days.

Last October he was admitted to the hospital with a fractured clavicle. This injury presented no particular interest, but the condition of the arm on the injured side attracted attention. The photograph shows the condition of the limb when he contracted the muscles, causing displacement of the unconsolidated fragments. The upper arm hung flail-like, it was markedly atrophied, the muscles were much thinner, and it was somewhat shorter than the right arm. The bone was plainly broken right across, and underneath the skin could be felt (the muscles being in a state of contraction) a marked projection formed by the pulling forwards and slightly inwards of the two broken ends of the humerus. The site of the fracture was exactly at the junction of the lower fourth with the upper three-fourths of the bone.

The skiagram shows that the thickness of the upper fragment has undergone considerable diminu-

tion for a distance of some four inches above the fracture. The lower fragment appears to be of normal size. The loss of substance on the part of the upper portion of the bone is no doubt due to the elimination of the three sequestra mentioned above, rather than to any actual atrophy.

On examination, one could feel very distinctly a strong fibrous band connecting the two ends, very resistent in spite of its suppleness. The triceps is well formed but the biceps is under-developed. Contraction of these muscles tends to bring the elbow nearer to the shoulder, and at the same time there is a slight curving of the arm, with the concavity forwards. As far as one could make out there were no adhesions between the periosteum and the neighbouring muscles, and the atrophied condition of the tissues rendered it possible to delineate the parts very easily. There was no

reason to suspect any interposition of muscle between the fragments.

The patient absolutely refused to allow anything to be done with the view of restoring the continuity of the bone, and, having regard to the tenuity of the upper fragment of bone, it is doubtful whether surgical intervention would have given a satisfactory result. He stated, moreover, that he was able to carry about his basket of trinkets (he is a pedlar) on this arm without pain or difficulty, and could, when necessary, lift comparatively heavy weights with that arm.

The case appears to me to be of interest, seeing that it is one of pseudarthrosis happening in infancy, a rare occurrence, since the statistics compiled by D'Arcy Power, an English surgeon, only comprise nine cases in which the lesion involved the humerus.

With respect to the causation of the lesion it is clear enough—*viz.*, undue pressure applied directly over the seat of the fracture, the presence of detached fragments of bone, which, by their displacement, probably in a transverse direction, tended to prevent proper coaptation and exerted dangerous pressure from within outwards on the neighbouring tissues, ultimately causing a limited area of necrosis through which they escaped.

The production of the pseudarthrosis necessarily interferes very considerably with the functional utility of the elbow. When the triceps and biceps are contracted to their maximum extent the angle formed by the two fragments of the humerus is approximately equal to the articular flexion, and when thus contracted the elbow-joint, which is brought much nearer the shoulder, merely serves to maintain the forearm in a direction parallel to that of the upper arm, and it is in this position that the patient is enabled to make use of his maximum muscular power.

The case is almost on all fours with that mentioned by Schwertzel, it being possible to bend the elbow to a right angle without causing the patient any pain; it would have been an interesting experience to endeavour to bring the fragments into close apposition, but the success of our intervention would depend in great measure upon whether the diminution in size of the upper fragment was due to the loss of bone tissue in the shape of the eliminated sequestra or whether, on the other hand, it was due to an atrophic process consequent upon interference with the vascular supply. Had the patient allowed us to operate I should have thought it desirable to effect grafts of bone in order to compensate, as far as might be, the actual loss of a tissue.

THE TREATMENT OF VARIOUS FORMS OF CUTANEOUS DISEASE BY THE X-RAYS AND LIGHT. (*a*)

By ALLAN JAMIESON, M.D., F.R.C.P.Ed.,
Physician for Diseases of the Skin, the Royal Infirmary, Edinburgh.

THE author first drew attention to the fact that when structurally intact the epidermis was highly impermeable, while if diseased and therefore porous, it might absorb unduly remedies applied to it. Hitherto our means of acting on the deeper parts of the skin had either been caustics or agents which occasioned irritation in the first instance. Some of the latter, according to Unna, might act by influencing metosis. Of recent years science had placed at our disposal various agencies, such as the X-rays, Finsen light, radium, and high frequency currents, which act on the tissue elements in and beneath the epidermis; the present paper deals with the first two only. His earlier work with the X-rays had been greatly hampered by the spring interrupter used, and it was only on the introduction of the mercurial interrupter that he had had favourable results. In using X-rays the treatment required to be carefully supervised, and the exposures suspended on the slightest sign of reaction showing itself. It was of great importance to screen healthy parts from the effects of the rays, as they caused baldness, the hair, however, growing again after the treatment was stopped. The best distance at which to place the tube was from four to six inches; he usually gave six exposures of five minutes on four days of the week. A moderate degree of reaction was not harmful, as it showed that the rays were taking effect, but it was generally, on the whole, wiser to interrupt the treatment as soon as any reaction manifested itself. He had seen burns occur in lupus, rodent ulcer, and favus, but not in mycosis fungoides.

Lupus.—It was sometimes advisable to supplement the X-ray treatment of lupus by painting with pure carbolic, especially when progress seemed rather slow. In some cases reaction occurred almost at once; in others it might be delayed for weeks. Hard tubes were generally less active; soft tubes, with a three-inch spark, were more effective, and not more likely to cause burns. He had noticed that the weather had considerable influence on the occurrence of reaction, which was most likely to take place, and to to be of severe type, on cold, raw days. Possibly other meteorological conditions might affect it also, just as one sometimes saw simultaneous rises of a number of temperatures in a hospital ward under certain climatic conditions; but apart from cold, he could not say what these were. In eighteen months he had treated 133 cases of lupus, 30 of favus, 21 of rodent ulcer, 12 of sycosis, and 2 of mycosis fungoides. Some of the lupus cases were partially, and other exclusively, healed by light, the rest by X-rays alone. He could not give statistics of cure, as nearly all were out-patients, and many discontinued attendance, but he could certainly say that all who persevered received material benefit. In lupus all the methods of treatment hitherto in vogue had had the disadvantage that while the centre of the patch healed, the disease spread at the periphery. Under X-rays this was not the case; where nodules reappeared they often did so in the centre of the patch. In lupus the soil had to be reckoned with, and cases in which the skin was soft, pale and tender, in persons of strumous constitution, were likely to react early, and did not offer so good a chance of cure. But even in these the treatment at least reduced the size of the lupus patch, and allowed of other means being more effectually employed. Dr. Jamieson then raised the question whether the treatment could induce tubercle to break out in other organs, instancing the case of a patient who, after having undergone a course of X-rays for lupus, developed tuberculous peritonitis, and

(*a*) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, on January 8th, 1904. For discussion see page 36.

after a second series of exposures, an abscess near the hip. He concluded that there seemed no reason to suppose that the sequence was other than accidental. The Finsen light acted best in small patches or nodules situated over bony eminences, which permitted of the part being blanched. The process was slower, less effective, and caused no burns. The lamp he used worked at ten amperes, but by increasing to eighteen amperes he had got better results. He had tried applying adrenalin previous to using the Finsen light, but did not think the results justified the extra expense.

Rodent ulcers were uniformly benefited, the hard margins receding and healthy epithelium advancing over the ulcer. The less the bones and periosteum were exposed the better were the results. In other forms of cancer the effects were not so good, and he had seen epitheliomata progressing while the rays were being used. Bad cases of rodent ulcer were the better for a preliminary scraping and treatment with chromic acid before being subjected to X-rays. The permanency of cure in any given case was doubtful, and relapse often took place after apparent healing.

Sycosis.—Only intractable cases had been treated, and in all the hair fell out, and the pustules disappeared. Unless all the disease was got rid of relapse was very likely to take place.

In *favus* the result of the rays was to remove all the hair and leave a smooth polished surface, on which healthy hair again grew. An aggregate exposure of an hour or more was required for this. There was no great tendency to reaction in this disease.

In *mycosis fungoides* the X-rays constituted the sole means of arrest known. The case which he had published some eighteen months ago still continued well, but some nodules had recently developed on parts of the skin which had never been subjected to X-rays. As to the mode of action of the rays in cutaneous diseases, it was not due to any bactericidal effect. Though sycosis could be cured, it was only by removing the hair and destroying the nidus on which the staphylococci grew, the vitality of the organisms themselves being scarcely diminished. In favus, too, the rays were merely an effective epilating agent. Possibly they promoted metosis, and in malignant cases it seemed that they recalled aberrant cells to the normal; how so, was quite unknown.

THE PATHOLOGY OF CHRONIC ALCOHOLISM. (a)

By WILLIAM FORD ROBERTSON, M.D.,
Pathologist to the Scottish Asylums Board.

THE author said he proposed to consider the inimical action of alcohol, firstly, upon the individual, and secondly, upon the race. The essential idea involved in a scientific conception of the nature of disease was that of a vital process occurring in response to a harmful stimulus. Disease might be defined as a chemico-vital reaction to an inimical force which had broken through the first line of defence of the organism. Alcohol, when brought in contact with the living body, readily passed the first line of defence and was capable of acting as an inimical force. After having briefly recalled the main facts regarding the general or physiological action of alcohol, he referred to the experimental and other observations, which showed that alcohol could have an extremely injurious effect upon the early stages of development. The experimental investigations of various workers had also clearly demonstrated that chronic alcohol poisoning had a very harmful action upon the defensive mechanism of the body, or upon immunity. This was a fact of great importance, and it served to strengthen the conviction that many had long had that the lesions which occurred in cases of chronic alcoholism in the human subject owed their severity and multiplicity to various forms of bacterial toxæmia. He believed that those secondary toxæmias were really the chief cause of the pathological changes in these cases. In addition to the weakening of the general immunity, there was an impairment of the local defences, especially in the upper portion of the alimentary tract, by the direct action of the alcohol. The chronic catarrhal changes, at first due to the action of the alcohol, became intensified by bacterial action, and a condition of chronic toxic infection from the alimentary tract was gradually established. Consequently the individual gradually developed various other disorders, located in accordance with his powers of resistance and various accidental circumstances. After referring to the special forms of chronic alcoholism, he briefly enumerated some of the more important morbid changes that occurred, and showed a number of illustrative lantern slides. He especially directed attention to the severe chronic catarrhal changes that could always be shown to be present in the alimentary tract.

Coming next to the inimical action of alcohol upon the race, he asserted the right of pathology to deal with the question. Pathology dealt with abnormal phenomena of cell-life. Mainly through the magnificent embryological work of Dr. J. Beard, the processes concerned with phylogenetic evolution had recently been brought into harmony with the cellular doctrine. Abnormal phenomena of phylogenetic evolution, as well as those of ontogenetic evolution, therefore, now fell within the province of pathology. He thought that the truth regarding the effect of widespread alcohol poisoning upon the race had not yet been grasped. The subject was really a part of the general question of the biological significance of disease, and as such he wished to consider it. In the results of Dr. Beard's work they had the foundations for a purely biological pathology which had hitherto been only a desideratum. He shortly stated the main facts that Dr. Beard had elucidated regarding the continuity of the germ-cells and the place and time of origin of the embryo. Dr. Beard had also shown that the mode of metazoan development was really that of an antithetic alternation of generations, and that there was thus one primitive mode of reproduction for the whole of organic nature. He pointed out some of the important corollaries of this new doctrine of development, and showed that it did not confirm Weismann's hypothesis, as some seemed to imagine, but rendered it superfluous and proved it to be in many respects at variance with the facts. They were now enabled to separate entirely the line of phylogenetic evolution from ontogenetic evolution. Offspring

(a) Abstract of Paper read before the Society for the Study of Inebriety, January 12th, 1904.

inherited nothing from their parents. The distinction between inborn and acquired character was really an artificial and useless one, and existing definitions could be shown to be erroneous. He next discussed the causes of genetic variation in the light of the facts of modern embryology and of evidence drawn from other sources. He contended that the generally accepted view that conjugation of germ-cells is a cause of genetic variation was entirely unproven, and probably erroneous; and that the real cause of such variation was the action of a changed, and especially an inimical, environment upon the germ-cells. He referred to the remarkable observations of De Vries upon the mutations of *Œnothera Lamarckiana*, and contended that these mutations were typical of what occurred in animals under the influence of new or inimical environmental conditions. Some of the mutations of this plant were adapted to their new environment, others were not. If organisms were perfectly adapted to their environment there would be no disease. This state was approximated to by many of the lower animal forms and plants living in natural conditions; when brought into a new environment they quickly manifested lack of adaptation to it. Their effort was towards adaptation to the new conditions, and this they attempted to achieve, firstly, by somatic variation, and secondly, by genetic variation. Some of the descendants were better adapted to the new conditions, but this advance was only achieved at the cost of the production of other individuals who were less adapted. These were more liable to succumb under the action of the inimical forces in their environment. This principle was exemplified in the fate of some of the mutations of *Œnothera Lamarckiana*. Imperfect adaptation to environment entailed somatic and genetic variation, and an increased incidence of disease in a certain proportion of the descendants. He maintained that in this country alcohol was at the present moment one of the most potent causes of genetic variation, as it was unquestionably of somatic variation, and that the incidence of diseases dependent upon defective resisting power on the part of the individual was thereby enormously increased. If these views were in accord with the facts, it was plainly the duty of a nation to do everything in its power to remove from its environment every inimical condition to which there was imperfect adaptation. He entirely dissented from the doctrines of the Read school in regard to the importance of "alcohol and disease" as causes of human evolution.

Clinical Notes.

POISONING BY BLACK HELLEBORE.

By JOHN C. THOROWGOOD, M.D., F.R.C.P.

INTEREST attaches to the black hellebore as being the first recorded purgative. Melampus, 1400 years B.C., is said by its use to have cured the daughters of Prætus of madness.

As an emmenagogue and purgative the tincture of hellebore has often been used in past years, and this tincture found a place in the last issue of the London "Pharmacopœia," the dose being 30 to 60 minims.

Morgagni has recorded a case where half a drachm of the extract was taken, causing death in sixteen hours. The patient, a man, æt. 50, had been under treatment for melancholia, and on departure from the hospital he took half a drachm of extract of hellebore. Active purgation with vomiting and abdominal pain came on somewhat later; he then laid down for a few hours and died quietly.

The post-mortem showed some amount of inflammation of stomach and intestine, the spleen was large and very soft, and the gall-bladder full of green bile.

The fatal result was attributed to the patient not having drunk freely of whey, a precaution it was customary to advise for all who took the hellebore. There is also a record of two persons who took hellebore root in cyder by the advice of a quack. Three-quarters of an hour after taking this dose violent symptoms came on without exciting suspicion as to the cause, so that one man took a second dose of the cyder; vomiting, delirium, convulsions and death soon followed. The post-mortem, sixteen hours after death, showed the lungs engorged with blood and the mucous membrane of the stomach and intestines blackish and almost in a state of gangrene.

These cases were communicated many years ago by M. Ferary to the Société Médicale d'Emulation at Paris.

BRITISH SANATORIA FOR CONSUMPTION.—XXVIII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

MUNDESLEY SANATORIUM, NORFOLK.

THE Mundesley district of Norfolk, as many a visitor knows, is peculiarly attractive in summer time. The climate is then well suited to the needs of many a tuberculous invalid. There is much sunshine, but little rainfall, a clear and dry atmosphere, and air that is well characterised as bracing. In the winter and spring it must be admitted there are drawbacks, but experience seems to show that at all times of the year a wisely directed medical supervision may secure beneficial results.

The Mundesley Sanatorium was specially designed for the treatment of consumptive cases, and opened at the end of 1899 under the care of Dr. Burton-Fanning and his cousin, Mr. W. J. Fanning, the former as visiting physician, the latter being resident medical officer. Recently the institution has passed into the hands of Dr. Noel D. Bardswell, who acts as resident physician, while Mr. J. E. Champman assists as clinical pathologist.

The sanatorium is situated about a mile from the sea and a similar distance from the railway station, in a somewhat isolated position. It is built on the southern slope of a sparsely fir-clad ridge which runs east and west, and is protected to some extent from the prevailing winds on the north, north-east, and north-west.

On the south the outlook is over rather uninteresting and slightly undulating agricultural country. On the east side lie the Mundesley golf links.

The soil is of sand, which extends to a depth of 180 ft., when chalk is reached.

The building is of wood, but is attractive and comfortable. The patients are accommodated on the south side of the ground and first floors. Some of the servants' quarters are in attics. The dining and drawing-rooms are on the ground-floor. The corridors, 8 ft. wide, are covered with linoleum, and run the whole length of the building. The chief entrance is at the east end. The patients' rooms are well appointed. Heating is effected by radiators, which, however, do not seem very satisfactory. Some of the rooms have open fireplaces. Lighting is by electricity. A verandah extends along the whole of the front of the building.

The grounds are thirty acres in extent and contain various conveniently placed and well-designed shelters.

As far as we could gather, the general management and daily routine were in accordance with modern requirements. Considerable attention is paid to dietetics.

A bungalow near the main building accommodates several patients.

At the time of our visit a very simple form of shelter accommodated two cases of working-class patients, who, in return for free treatment, were submitting to

careful investigations respecting dietetic procedures. Some interesting experiments were proceeding on the influence of a vegetarian diet in the maintenance of nutrition in the phthisical.

Very careful clinical records are kept of every case, and much valuable scientific data is being collected.

The patients are allowed opportunities for carefully regulated exercise, but we were surprised to find that golf was not interdicted.

An attempt was recently made to deal with cases belonging to the working-class in a separate building at Mundesley at the remarkably low rate of 17s. a week; but we were informed that the experiment did not prove a success and has been abandoned.

The terms at the Mundesley Sanatorium are five guineas a week, inclusive of everything except personal laundry, stimulants, extra nursing, and special invalid diets. Mundesley is a terminus of the Great Eastern and Midland and Great Northern Joint Railways. Carriages by arrangement will meet patients on their arrival.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question raised by Dr. Eyre Harris in your last issue, as to the possibility of modifying the old-fashioned hospitals for chest diseases and ancient institutions for the treatment of pulmonary tuberculosis to meet the strict requirements of sanatorium life as now understood, is one of great importance and should be faced in all its bearings by those responsible for the conduct of these establishments. It has been my duty to point out in the articles on the various British sanatoria for consumption which I have contributed to your pages that these are of "all sorts and conditions," some suffering from structural deficiencies, while others lack in efficient management. It is very doubtful if it is not false economy to attempt extensive alteration of the ancient to fit the fashion of the modern. Certainly in the case of many of our hospitals no amount of alteration will enable these institutions to supply what are now considered as hygienic necessities. I am still of opinion that the Committee of Management of the National Sanatorium at Bournemouth should consider whether, instead of providing such further additions as are contemplated on the present very limited site, it would not be wisest to recognise that no amount of alteration can modernise an establishment founded as far back as 1855; steps should be taken to provide an establishment where the "open-air" method can be applied in their entirety in accordance with the best knowledge of the day.

As I was careful to point out, many valuable improvements have been carried out at the National Sanatorium at Bournemouth, and splendid attempts are now being made to secure a high standard of efficiency, but I must continue to hold to my former opinion as expressed by Dr. Harris himself, that "one cannot expect to alter an existing building so that it will have quite the same appearance as one of the modern sanatoria."

I am, Sir, yours truly,
SPECIAL MEDICAL COMMISSIONER.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JANUARY 8TH, 1904.

DR. FREDERICK TAYLOR, President, in the Chair.

SIR DYCE DUCKWORTH and Professor HOWARD MARSH read notes of a case of

PNEUMOCOCCAL PERITONITIS.

The patient, a woman, æt. 27, was seized with headache, generalised pains and a rigor on February 26th, 1903. The temperature was found to be 104·2 on the following day, and symptoms of general peritonitis followed. Widal's reaction was negative, and a large, polynuclear leucocytosis was present. On March 2nd, Mr. Marsh and Mr. Bowlby saw the case, and a diagnosis of typhlitis with some general peritonitis was made. Mr. Marsh operated, and signs of inflammation were seen in the peritoneum and large intestine. The appendix was found to be constricted at the base, dilated, and full of mucus above; it was ligatured and removed. There was some thin, turbid, and dark-coloured fluid in the peritoneal cavity, but no adhesions were found, nor was there any evidence of the perforation of a viscus. A culture of the fluid showed pure specimens of the pneumococcus, the presence of which was confirmed by an inoculation test. Three days later hiccough and abdominal pain supervened, and 10 c.c. of No. 1 antipneumococcic serum were injected. On March 6th, the injection was repeated. Signs of fluid at the left base appeared, and on March 20th pus was found on exploration, resection of part of the ninth rib being performed the next day, when twelve ounces of sour-smelling pus were evacuated. The further progress of the case, though slow, was uneventful. The sudden onset and rapid and grave development of the peritonitis closely corresponded with what is observed in pneumoccoccic inflammations elsewhere.

The PRESIDENT also communicated a case of

PNEUMOCOCCAL PERITONITIS

in a girl, æt. 8, who was admitted under his care into Guy's Hospital on November 19th, 1903. On the 10th, abdominal pain set in, followed by a rigor, and two days later signs of pneumonia developed. On admission, the abdomen was distended and tender, moving very little on respiration, while physical signs of consolidation at both bases behind were present. Some herpetic vesicles were seen at the base of the nose. Mr. Lucas performed laparotomy, and a quantity of odourless pus together with masses of lymph was removed. The cavity was irrigated with hot saline solution and drained. The pneumonia on the right side cleared up, but on the left side physical signs of empyema manifested themselves, and on the 27th six ounces of pus were withdrawn, resection of a portion of rib being performed four days later, when more pus was evacuated. Cultivations taken by Dr. Eyre from the peritoneal pus gave a pure growth of the pneumococcus; those taken from a second collection in the left iliac fossa, which was incised on December 11th, a growth of pneumococcus associated with the staphylococcus aureus. Cultivations from the pus aspirated from the chest were sterile, but under the microscope showed badly staining diplococci, and empty capsules, characteristic of a pneumococcic empyema. The child was making good progress. Dr. Taylor discussed the question of the seat of primary infection which, he thought, was shown by the sequence of events to be the lung, and the peritonitis and empyema he considered were secondary.

Mr. STANLEY BOYD referred to the case of a woman, æt. 26, whom he had operated upon for symptoms of peritonitis, three pints of odourless pus being evacuated from which pure cultures of the pneumococcus were obtained. The abdomen was distended in a peculiar fashion and moved with surprising ease. No information was forthcoming at the time of operation as to the primary origin of the disease.

Dr. J. H. BRYANT alluded to three cases of pneumococcic peritonitis which he had published in 1901, in which the primary point of infection was the peritoneum. He considered that an alimentary origin was not at all improbable, especially as the pneumococcus might be found in the throats of healthy individuals. He called attention to the fact that abdominal pain was frequently complained of in pneumococcal pneumonia, and he thought that the adhesions sometimes found post-mortem between the lung and the diaphragm might account for this.

Dr. J. FAWCETT stated that in 182 fatal cases of lobar pneumonia occurring in Guy's Hospital during the last five years, in which autopsies had been made, five only showed any evidence of infection of the peritoneum, and this was very slight. The conclusion to be derived was that in pneumococcal peritonitis the infection was generally primary in the peritoneum.

Dr. W. LANGDON-BROWN referred to a case of pneumococcal empyema in a girl, æt. 10, in whom signs of fluid appeared in the abdomen and right knee-joint. The abdomen was not opened, as the condition cleared up. He considered that this was probably a case of

pneumococcal peritonitis which got well without surgical interference.

Mr. C. H. GOLDING-BIRD said that although a tuberculous appendicitis was known, yet pneumococcal appendicitis was not, as yet, recognised. He thought that there were many points in Mr. Marsh's case which might justify the latter description.

Dr. J. EYRE felt sure that if bacteriological examinations were made more frequently than they were the pneumococcus would be more often found. He called attention to one curious property possessed by the pus from these cases, namely, its tendency to auto-sedimentation, the upper layers soon becoming clear. He thought that such a simple test might be found of assistance at the time of operation. He also pleaded for the importance of performing animal inoculation experiments as a confirmatory test for the presence of the organism.

Dr. HERBERT FRENCH read notes of a case under the care of Mr. Newton Pitt, in which he had performed the autopsy. Acute peritonitis with consolidation of one base were found. He thought that the cases might be divided into two groups, one where the infection is directly into the peritoneum, and another in which the organisms get into the blood and so disseminate themselves.

Sir DYCE DUCKWORTH, in replying, said that he thought that pneumococcal peritonitis might exist in varying degrees of virulence. The improvement in his case after the use of the serum was certainly *post*, if not *propter, hoc*.

Professor MARSH replied that he was unable to state whether the case was one of primary appendicitis. He thought that to the list of conditions which may imitate appendicitis pneumococcic peritonitis must be added.

The PRESIDENT, in replying, said that the presence of an extra-peritoneal abscess containing pneumococci in association with another organism was an interesting feature in his case.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JANUARY 8TH, 1904.

MR. JOHN CHIENE, President, in the Chair.

DR. WM. ALLAN JAMIESON read a paper on—

THE TREATMENT OF SKIN DISEASES BY X-RAYS, &C.,

an abstract of which will be found on page 32.

Dr. NORMAN WALKER, in the discussion that followed, said it was very important to consider each case on its own merits, especially as to the duration of the sittings. For example, in a working-man it was better to give a long exposure in one or two sittings; a burn resulted, but the cure was not interfered with, and the patient could go on with his work while the burn was healing. In this method telangiectases were often produced in the scar, but this was of minor importance, as they could be easily treated by electrolysis later if desired. Again, in patients who could not attend daily over long periods, and who at the same time did not wish to have burns, ten-minute exposures at intervals of ten or twelve days might be tried, and a cure could ultimately be attained in this way. In rodent ulcer, if the case were seen early, it was always a question whether excision should not be preferred to X-rays; he thought it should. It was always difficult to say when treatment should be stopped, as after apparent cure relapse was often seen. When once a rodent ulcer had attacked the cartilages the outlook was not nearly so good. As to other skin diseases on which the X-rays had been tried, they might be divided into those in which there was reason for supposing that the treatment would succeed, and those in which its use had been found accidentally. In hypertrichosis he considered that the margin between permanent destruction of the hair follicles and sloughing of the skin was too small for safety, and that therefore the treatment was not to be recommended. In favus, which he looked upon as practically incurable by other means, the method was the best at our disposal. In ringworm he did not advise it, unless there was some especial reason for hurrying on a cure. In these diseases and in sycosis it acted solely because of its efficient epilatory action. He had used X-rays in the treatment of an extensive case of warts of the scalp with great benefit; the growths, which numbered about 200, disappeared after seven or eight sittings. In psoriasis, though the lesion was improved, the results on the whole were not so good. He had not tried it in eczema, nor did he propose doing so. A word of caution as to tubes bursting was needful; they should be wrapped in gauze to minimise the risk of glass splinters flying about. There was no evidence that X-ray treatment caused dissemination of tuberculosis; in Wilde's series of eighty cases of lupus two died of phthisis, probably quite an accidental proportion. His experience rather was that the general health of the patients improved under treatment. Dr. Wilde, of Manchester, was able to compare all methods of treatment, and found that with X-rays he had 75 per cent. of cures, with Finsen light 74 per cent., and with the London Hospital lamp 24 per cent. Dr. Walker did not therefore think it was justifiable to replace their small lamp by the expensive Finsen one, seeing that the results were not better than with the X-rays. He strongly urged that to save all methods of electrical treatment from falling into disrepute they should be kept in the hands of scientific physicians and not exploited by quacks, companies and electrical institutes. Not less strongly did he assert that despite the brilliant results got in malignant disease, all such cases should be treated surgically if they were got early, and X-rays looked upon as a secondary resource only.

Dr. DAWSON TURNER gave statistics of the cases he had treated during the past six months. Of twenty-three of rodent ulcer, seven were cured, twelve improved, and four died. Of forty-two of lupus, eighteen were cured and twenty-four improved; of three of cancer of the cervix, two were improved and one died; of thirty-five of tuberculous glands, twenty were cured, twelve improved, and three not improved; of six of tuberculous joints, one was cured, three improved, and two not improved; of twelve of epithelioma of mouth, four were improved, eight not improved; three cases of sarcoma were improved; of nineteen of scirrhus of the breast eight were improved, eleven not improved. Sarcoma yielded much more readily than carcinoma; an extensive fibro-sarcoma of the frontal bone, which had mechanically caused complete blindness for four years, had diminished so greatly as no longer to interfere with vision in eleven sittings. An ulcerated scirrhus had healed, and remained so for a year. As to voltage, it must be high enough to carry the current through the tube; the more amperes got through the better. The length of exposure varied inversely as the square of the distance of the tube. For superficial lesions a soft tube should be used, for deeper ones a hard tube. He thought that there was some reason to fear metastasis in malignant disease, as he had seen a scirrhus develop in a healthy mamma after a scirrhus in the other breast had been healed by X-rays.

Dr. FRASER (Dundee) thought that the more aberrant the tissue cells were the greater was the effect of the rays. Their bactericidal action was less important; they altered the nutrition of the cells in some way and laid them more open to other treatment. Soft tubes caused more irritation than hard ones, their effects being redness, swelling, loosening of hairs, pigmentation, blistering, and sloughing. The factors influencing the results were the strength of the current, the hardness of the tube, the distance, the duration of exposure, the state of the skin, and the individual reaction; he had not noticed that weather had any effect. In lupus and rodent ulcer the abnormal cells were destroyed, the growth of healthy fibrous tissue stimulated, and the natural epithelium favourably influenced. In favus his results had been good. In scirrhus, large rodent ulcers, and sarcoma he had noted a marked analgesic action even where no healing

took place. In lupus erythematosus his results were very good, the scars being soft and not contracting. Telangiectases were common.

Dr. GREIG (Dundee) alluded to the success he had attained in treating mycosis fungoides by X-rays, and Dr. F. GARDINER to their applicability to hypertrichosis, in which, he thought, the margin of safety was larger than Dr. Norman Walker had represented it to be.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, NOVEMBER 27TH, 1903.

The President, DR. A. SMITH, in the Chair.

DR. SMYLY showed an interesting fibro-cyst of the uterus and a sarcomatous tumour which occurred at the seat of operation six years after an ovariotomy.

The PRESIDENT showed a specimen of tubal pregnancy strangulated by torsion of the pedicle.

Dr. GLENN proposed, and Dr. KIDD seconded, that the best thanks of the Section be accorded to the outgoing President (Dr. Smyly).

The PRESIDENT then read his address on

THE EFFECT OF THE MIDWIVES' ACT OF 1902 ON IRISH TRAINING INSTITUTIONS AND NURSES,

a full report of which appeared in our issue for December 9th. In the discussion of the address which followed, Dr. TWEEDY proposed a vote of thanks to the President for his able address. "I wish also to convey my congratulations to him," he said, "for the high position in which he has been placed as head of the Obstetrical Section of the Royal Academy of Ireland by a unanimous vote. In reference to the Midwives' Registration Act, I fear that our profession cannot be held blameless for the present condition of affairs. When it became apparent to everyone that rightly or wrongly the English public intended to have the Bill as it at present stands, there was no unanimity of opinion among our professional brethren here. Dr. Smyly alone, so far as I know, held consistent views, and urged the importance of having Ireland included in the benefit of the Act. It was not until the Bill had almost become a law that those in authority in the Rotunda aroused themselves to obtain certain privileges for the chartered hospitals of Dublin. These privileges, I understand, only extend to the year 1905, and, such as they are, we share them in common with every 'handy woman' in England. After 1905, women who wish to practise midwifery in England will have to pass a State examination; before presenting themselves for this certain conditions will have to be fulfilled, which render it impossible for Irish nurses to enter for it. The Rotunda is the largest hospital of its kind in the three Kingdoms; 170 women have crossed the water to enter it as nurses within the past five years; that in itself is sufficient proof of the value attached to our certificates. Yet this miserable rule of having to attend a woman for ten days after confinement absolutely makes it impossible for our nurses to qualify. It is a fact of common knowledge that the lying-in women in the Rotunda only spend eight days in the institution; and, consequently, the 'handy woman,' in the English villages, who has muddled through her twenty conductions, and has tended for ten days in each case, will be adjudged more worthy to present herself for examination than our nurses. If we agree on some common course of action we shall surely succeed in getting the Privy Council to alter the rules that at present exist; and I hope that before we leave this evening some resolution will be adopted that will be the means of removing the injustice that so nearly threatens us."

Dr. KIDD, in proposing "That in the opinion of the Obstetric Section of the Royal Academy of Medicine in Ireland, any woman holding the nursing certificate of the Irish Chartered maternity hospitals shall be deemed to have complied with the rules of the Central Midwives' Board regulating the course of training of 'pupil midwives,' and shall be eligible to present herself for the examination of the Central Midwives Board," said: "After the very able address we have heard from our President my task is an extremely easy and pleasant one. In this resolution which you have just heard, I think there is nothing contentious to a member of the Obstetric Section of the Royal Academy of Medicine. Professor Smith pointed out very clearly the difference which exists between the training of midwives here in Ireland and that which, under the terms of the Act, would entitle the ordinary midwife in England to present herself for examination by the Central Midwives' Board. Dr. Tweedy mentioned that eight days was the recognised number of days spent by a patient in the maternity of the Rotunda Hospital; I believe that nine days is the number at the Coombe; but any person who has had experience knows the extreme difficulty there is in keeping that class of patient in hospital, even for so short a time. With regard to the allocating of twenty conductions to each nurse, I think that instead of doubling the size of our hospitals we would have to double the number of births. Dr. Tweedy has pointed out that no less than 170 midwives who were trained in the Rotunda hospital during the last five years went over to practise in England. I think that if this point were brought prominently forward it is the one and sole proof needed to show the estimation in which the diploma of the Rotunda Hospital is held in England. With regard to the clause which gives us two or three years' grace, it really reduces the nurses who have received the certificate of the Rotunda or the Coombe to the level of the 'handy women' in England. I think that if this resolution be adopted, and if pressure be brought to bear on the Privy Council to alter the rules so as to allow the admission of our trained nurses to the examinations of the Central Midwives' Board, we should succeed in getting justice done to the chartered hospitals of Dublin."

Dr. JELLETT, in seconding Dr. Kidd's resolution, said "that he would like to point out that the present difficulty of the Dublin hospitals was brought about not by the provisions of the Midwives' Act, but by the regulations of the Central Midwives' Board sanctioned by the Privy Council; and that it was, therefore, possible to overcome it, as these regulations could be changed. There was not the least occasion for the Dublin hospitals to lose heart. If the proper stand were made, the changes were sure to be effected. The present regulations practically prohibit the training of nurses in Ireland for English districts. Now there are two ways out of the present difficulty open to the Irish hospitals. They can claim either that their examinations are recognised as equivalent to the examination of the Central Midwives' Board, or that, in the terms of the resolution, the certificates of the Irish hospitals shall be taken by the Central Midwives' Board as evidence of sufficient training, though this would seem to be self-evident to anyone. It was interesting to note the attitude of the promoters of the different Bills towards the Irish hospitals in the past and at present. (The speaker then read some correspondence which passed between the College of Physicians and the promoters of the Midwives' Bills of 1900 and 1902.) When the Bill of 1900 was before Parliament, Mr. Heywood Johnston expressed a willingness to accept an amendment recognising the examinations of the Irish hospitals as equivalent to the examination of the Central Midwives' Board. When the Bill of 1902 came forward, he refused to accept such an amendment, but at the same time disclaimed any hostility to the Irish hospitals, and stated that in his opinion the Bill would not injure them. Now that the Bill is law, the first act of a Board largely controlled by the promoters of the Bill is to draw up rules which effectually exclude Irish nurses. He had written to Dr. Sinclair, a member of the Board, and asked him what would be the position of an Irish nurse who applied to be admitted to the examination of the Board, and said:—"I have been a pupil midwife for

six months at one of the Dublin Incorporated hospitals. During that time I have attended a regular course of instruction; I have watched some 300 to 400 deliveries; I have personally assisted at some 20 to 30; I have personally conducted some three or four; I have watched some 600 to 800 women during their puerperium; and I have personally nursed some 20 to 30. I have passed the examination of the hospital.' Dr. Sinclair, in reply, had stated that the Board had said that it was bound by the Privy Council rules, but that he considered that the Irish hospitals had a substantial grievance which called for removal. What were they going to do? The resolution of the Academy must be backed unanimously by the hospitals, by the Royal Colleges, and by extraneous opinion, and then it could not fail. The Central Midwives' Board was undoubtedly a powerful body, but when it went too far it could be pulled up by the Privy Council as had been done before. Of the present regulations some were good and some were bad; and it was a curious fact that, as was commonly hinted, almost all the good regulations were recommended by a minority of the Board, were refused by the majority, and were finally forced on the majority by the Privy Council. In other words the majority report was, to a very large extent, rejected by the Privy Council, and if the Privy Council had compelled the Central Board to change their regulations once, it could make them do so again. But to succeed there must be absolute unanimity between the Dublin hospitals. The worst enemies of these hospitals could not accuse them of over zeal in their own behalf in the past."

Dr. SMYLY: "The resolution I have to propose is one of great importance to our country and profession, and, therefore, should arouse the most intense feelings of patriotism and professional *esprit de corps*. It is that this Midwives' Act should be extended to Ireland. For many years I have felt it to be a very desirable Act both for England and Ireland, and at first I worked with some energy for its passing; but when I found that Ireland was excluded from the Act, and that we were excluded from all the benefits of it, it seemed to me that we should suffer a double wrong—we not only get nothing ourselves, but we are deprived of our present privileges. I think this Act would be of benefit to us in three ways. First, to poor lying-in women in Ireland. It has been said to me often that we did not want the Midwives' Act over here when we have a Poor-law that provides midwifery for necessitous women. I give my opinion—it has been formed from some experience among the poor of Dublin and elsewhere, and not founded on statistics, so it may clash with and be different from the opinion of other people. But it is my opinion that in the poorer parts the lying-in women are not attended by trained nurses, but by ignorant women who have no training whatever, and are popularly known as 'handy women.' I am sure we can all remember instances in which injuries have been done by these women. No women will be allowed to practise midwifery again without certificate—that is, in England. If the Bill extended to Ireland the effect would be that these poor women would be attended by trained nurses. However superficial such training might be, she would at least have learnt the use of antiseptics, the methods of cleanliness, the prevention of puerperal fever, &c., and she would know when to send for a doctor. If under the Midwives' Act a nurse meet with a case of malpresentation, hæmorrhage, and so on, and she does not send for a doctor, she is liable to have her name erased from the midwives' roll. If guilty of drunkenness, or immorality, she would be liable to punishment. How does this Bill affect the medical profession? The midwives have to send for a doctor if anything is going wrong, and this entails a lot of work for doctors which they might otherwise not have got. And as midwives are compelled by Act under the County Councils to send for the doctor, I believe the people who compel the sending for the doctor will have to pay him; but this is not quite clear. The third reason why the extension would be beneficial to us is that of the great training schools here. If we fail in our appeal to the Central Board and to the Privy Council, we shall be in an unfortunate condition, and the Rotunda will receive a very great blow. If we had united to get the Act extended to this country, we should have had our representatives on the Central Board, and their rules would not have passed in their present form. As this resolution appeals generally to the profession in Ireland, I propose that a copy of it, if passed, be sent to the authorities of the Irish Medical Association."

Dr. HORNE said "we had to go back some twelve or fourteen years since this Bill was proposed, and ask who were its promoters. Not the medical profession, but a lay society and Mr. Heywood Johnston. The Obstetric Section of the Royal Academy of Medicine had the Bill under discussion. When it came before us it was said it did not affect us at all; it was a Bill for England and Wales. We thought our poor people in this country well nursed indeed, for we had the Coombe and the Rotunda Hospitals, which were sending out nurses all over the country. A second attempt was made to carry the Bill, but it was still resisted by the profession, as against their rights. A third time, it becomes law. It is because it is law that I feel justified in saying that it should be extended to Ireland. However, there may be some difficulties about its extension to Ireland. Dr. Smyly has mentioned one very important point. How will the medical men receive it? How will the County Councils, if they find they have to pay the costs? I do not think that a trained nurse will go, say, to the Arran Isles for a salary of £15 a year. However, the meeting very properly decided that the resolution ought to go before the Irish Medical Association in order that the profession may give their opinion on it. I wrote the other day to the secretary of the Midwives' Board, asking for explanations, first as to the nurses' certificates in training, and those to come afterwards. I got a reply stating that my letter would be laid before the Board in due course. There is no necessity for action until they say they cannot receive our certificates. If they do not, I think this Bill ought to be extended to Ireland, but with very decided amendments. I think that in centres like Dublin and Belfast the right should be reserved for nurses to train just as at the present time, for it is only in big clinical centres that attendance should be recognised, and certificates given."

The resolution was put to the meeting and unanimously adopted.

Dr. STEPHENS proposed that the resolution of Dr. Kidd, which was seconded by Dr. Jellett, *re* the chartered hospitals, should be sent to the Central Midwives' Board, and to the Privy Council. On account of some remarks of Drs. Tweedy and Jellett, he would like to state that his Board had been willing to co-operate with Rotunda Hospital, and had sent a communication to the Board of that hospital which had not received any reply. He added that his Board would be only too happy to act with the other hospitals, for it was only by united action they could hope to prosecute their claim successfully. He was there on behalf of his Board to join in any resolution they might adopt, and he was heartily in agreement with the opinions of the meeting.

Dr. BARRY seconded the resolution, and thought it was one that should be accepted without hesitation, for it was no more than justice that they should have good nurses not only here but across the water. The united action of the hospitals would be bound to get them what they wanted, not as a favour but as a right.

The resolution was adopted and the Section adjourned.

SOCIETY FOR THE STUDY OF INEBRIETY.

MEETING HELD IN THE ROOMS OF THE MEDICAL SOCIETY OF LONDON. Tuesday, January 12th, 1904.

H. CAMPBELL, M.D., F.R.C.P., President, in the Chair.

W. FORD ROBERTSON, M.D., Pathologist to the Scottish Asylums, opened a discussion on "The Pathology of Chronic Alcoholism," and illustrated his paper (an abstract of which will be found on page 33) by lantern slides.

NORTH-EAST LONDON CLINICAL SOCIETY.

A MEETING of this Society was held at the Tottenham Hospital on January 7th, at 4 p.m., the President, Dr. J. Hunt, being in the Chair. Dr. A. J. Whiting showed (1) a case of angio-neurotic œdema in a female patient, æt. 19. Areas of spastic œdema had developed themselves over different parts of the body, including the pharnyx. The affection was in no way dependent upon any error in diet. The treatment of the case evoked considerable discussion, many members expressing the view that some derangement of the gastro-intestinal canal would, in all probability, play an important part in the production of the disease, while others maintained that the disorder had its origin in a vasomotor neurosis. (2) A case of lymphadenoma in a boy, æt. 14. The bilateral glandular swellings in the neck at one time obstructed the respiration. He had materially improved under the administration of arsenic and cod-liver oil. Dr. R. Murray Leslie, under whose care the boy was at one time as an in-patient, considered that the condition was both clinically and pathologically distinct from tuberculosis, with which it was often confounded, and that its mode of spread more resembled that of the sarcomata. Dr. Norman Meachen showed a case of lichen planus in a married woman, æt. 31, illustrating the lichenoid transformation of scratch-marks. Her condition was improving rapidly under the administration of arsenic internally and the local application of a creolin lotion.

PARIS, January 10th, 1904.

OPOTHERAPY IN RENAL DISEASE.

As mentioned last week, M. Renaut, of Lyons, made a communication at the Académie de Médicine on the application of the treatment of renal opotherapy to albuminuria, and on account of its importance we give a more detailed *résumé*.

This treatment, he said, applied to patients suffering from renal insufficiency, constitutes the most active and the most efficacious of all proposed up to the present moment. Better than any other known means, it opens the kidney, practically annulled by uræmic œdema; it acts rapidly and surely, exercising intense diuretic effects; when sufficiently prolonged, it brings the urinary secretion to its normal quantity and maintains it there. The method has the advantage over most others in the fact that it surely reduces the albumin emitted by an insufficient kidney and restores to the latter its full activity.

It can even cause the albumin to disappear for long periods, giving a chance, by the prolonged functional rest, to favour the restoring of the renal epithelium. It is also a first class antitoxic method, and one which is in no way destroyed by its passage through the digestive tract, a very important point.

As to its mode of administration Professor Renaut minces every day, one, two, or three pork kidneys. Pounded in a mortar, a pint of salt water is added. After four hours the water is decanted and drunk by the patient in three or four doses in twenty-four hours. The treatment is followed for ten days and a rest of four or five days is ordered, after which the treatment is recommenced.

We have here, concluded M. Renaut, a therapeutic method which should be currently employed at the beginning of all cases of nephritis, without, however, renouncing the other means known and put into practice.

M. Dieulafoy confirmed the report of his colleague by saying that he had warded off more than once acute uræmic attacks by the ingestion of raw kidneys, while Professor Cassaet, of Bordeaux, employed with complete success the same treatment (daily ingestion of raw kidneys) in a case of suppuration of the kidney from renal calculus.

ANTITHERMICS IN TYPHOID FEVER.

As everyone knows, the treatment of typhoid fever has varied according to the experience of the practitioner. While some give every confidence to quinine, others prefer antipyrine, and still others pyramidon, which they say possesses none of the inconveniences of the two former. Naturally those antithermics receive only their full application where cold baths are not or cannot be accepted by the patient. To the above list a new agent has just been added which, if reports are true, would seem to give particular satisfaction. Cryogenine, according to M. Hortoles, of the Montpellier Academie de Médicine, possesses real advantages, especially in the treatment of typhoid fever in children.

In spite of baths and quinine associated with antipyrine, the temperature in a case which he was attending rose persistently for ten days. Given in the dose of ten grains every four hours the temperature fell each time one and a half degrees, and during the whole period of the malady cryogenine was constant in its effects. A short time after its administration the patient perspired freely, but no intolerance of the drug was noticed.

SYPHILIS IN THE INFANT.

According to M. Schwab, injections of biniodide of mercury in a watery solution are superior to all the other classical methods, and the hypodermic treatment should take the place in the treatment of infantile syphilis. Without danger it seems particularly efficacious, rapid, and certain. The average dose should be from one to two milligrammes given each day for ten or fifteen days, and then suspended for a similar number of days when a new series of ten injections should be made.

His formula is as follows:—

Biniodide of mercury, 0·05
Iodide of sodium, 0·05
Distilled water, 10 gr. (cubic centimetre).

This solution contains 5 millig. of mercury per cubic centimetre (Pravaz syringe); 4 divisions of the syringe representing 1 millig. should be injected into the lumbar region. It is generally recommended to make the injection into the muscles, but the subcutaneous cellular tissue presents no inconvenience.

The same aqueous solution of biniodide of mercury is very efficacious in syphilis of the adult, but, of course, in much larger doses, 6 to 8 centigrammes every five days.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 9th, 1904.

AT the Society für innere Medizin Hr. A. Loewy gave an address on

THE ACTIONS OF HIGH AND SEA CLIMATES ON THE ORGANISM.

Although the action of the former had frequently been the subject of investigation during recent years, that of sea climates had never been properly estimated. The speaker, along with Dr. Franz Müller, had carried out investigations on the climates of Westerland and Sylt as to the effect on tissue change in three individuals, and the report embraced the results then obtained, and also the results of his earlier investigations on high climates.

A high climate acted stimulatingly, it increased the

activity of the heart, the respiration, and tissue change. Even when the body was at rest the pulse-rate was higher than at the sea level, as also the frequency of respiration and the volume of inspired air. With muscular exertion, also, all these processes were at higher values than on lower levels. These increases were higher according to the height and especially in proportion to the excitability of the individual, but they were also of a transient nature: they fell after some days or weeks —they did not depend on the rarity of the higher air. Other factors must also be taken into consideration—intense isolation, rapid movements of air and temperature. In contrast to this, however, was the action of a high climate on blood formation, which was permanent, that is, acting as long as residence in the high climate lasted, and dependent directly on the rarefaction of the air. An actual stimulation of blood formation must be conceded, for the increase in the total hæmoglobin constituents could be confirmed by the speaker, and it could be determined that the medulla of bones of animals of high altitudes was richer in blood cells than the marrow of similar animals on the lower planes, and represented red marrow as compared with the fatty marrow of the latter animals.

As regarded two of the individuals experimented on, it was shown that the sea climate also stimulated tissue changes, one much more than the other, but for a shorter time, the other less but more lastingly. The third person showed no increase. The increase began even on the second day of residence, and before there could be any direct effect.

It was worthy of note that in the case of the speaker, both high and sea climates increased tissue changes, but with Müller the high climates had no distinct effect. There were therefore individual differences in regard to such action.

The stimulating effects of sea and high climates must be looked upon as specific actions, as the individual factors, the total of which caused them, but which could not be caused by any of them individually.

In any case sea and high climates were by no means indifferent curative agents; they stimulated and should be employed with caution when conditions of excitement were already present. Individualisation was to be desired, as they did not act on all individuals alike, rather one would be more active in one case and another in another. For any regular rules to be laid down in this respect, however, further investigations were necessary.

At the Medical Society Hr. Holländer spoke on the

TREATMENT OF PRIMARY SORES,

the communication being a preliminary one. He spoke on the endeavours that had been made to prevent the outbreak of syphilis by cutting out or destruction of the primary sore. Only rarely had any result been seen from it. Moreover, one could not always say from the character of the sore that it was not a simple ulcer. For this reason statistics were comparatively worthless, and only such were of value as were based on a large series of cases.

In the belief that contactless hot air cauterisation effected a decidedly deeper action than Paquelin or the hot iron, he had employed hot air cauterisation in 59 cases of primary sore. Of the number 15 became syphilitic, 44 were spared, 22 of these had remained well over a year, 12 more than 6 months, 3 acquired a re-infection.

If one had cauterised a sore with hot air and tried to scrape off some of the slough with the sharp spoon, nothing came away. If the sore were a soft ulcer, however, a bleeding wound would be left from the curetting. This differential sign the speaker looked upon as positively typical, and he included only those cases that had the characteristic hard surface. He believed that by this method a larger number of cases could be saved from general infection than in any other way.

Austria.

VIENNA, January 9th, 1904.

SENSATIONAL PARALYSIS.

URBANTSCHITSCH read an exhaustive paper to the Gesellschaft der Aerzte on the subject of perverted sensation and its remote effects through the reflex system on the motor nerves. To illustrate his subject he quoted cases of catarrh, polypi, and simple thickening of the middle ear producing paresis and even paralysis of an entire motor region. The sensation of calculating weight is not an uncommon occurrence in aural disease. A finer disturbance is frequently observed in the arm while writing, and the tongue in speech. He gave fifty examples of the former from tamponing; in eleven cases the paralyses were greatly aggravated by laying the middle ear space quite open, and then applying the tampon. Writing and speaking were the tests regularly applied in carrying out these observations. In one of these cases the patient became utterly unable to write at all, although a good penman when in health. As soon as the tampon was withdrawn, speech and power of writing would return. Out of the fifty cases experimented on with the tampon pressure, thirteen were affected in speech as the earliest manifestation, and particularly in attempting to pronounce the letter "s," and in this respect the condition very much resembles aphasia.

The motor reflex may also be associated in the most deceptive manner as apoplectic attacks, which will certainly increase the attendant's alarm. Proper attention to the ear will immediately relieve the excitement, which, he considers, fully testifies to the reflex functional character of the disorder.

From these facts he reasoned that the same results were obtained from similar influences on the mucous membrane of the nose, mouth, &c., which need not be confined to the motor sphere, but may be passed on to the damage of other sensations, such as taste, smell, temperature, &c. He found that cocainising the mucous membrane before applying the tampon abolished the consequent disturbance, another fact which proved to his mind that the morbid changes were of a reflex nature.

ETIOLOGY OF EMPHYSEMA.

Golubow, of Moscow, in describing the history of a case of emphysema arising from an aneurysm of the aorta said that in this case chronic tracheitis followed, with a consequent emphysema of the lung. The true etiology, however, of this disease was due to a congenital anomaly in the cartilages of the ribs. If the number attached to the sternum were reduced to three or four, leaving seven or six of the ribs attached by cartilaginous union at the lower part of the chest, the lung thus protected would in all probability be emphysematous.

PROSTATE GLAND.

Englisch again presented an exhaustive monograph on urologic pathology, in which his results differ somewhat from other authors, in acting upon the supposed valves at the neck of the bladder, or rather the folds in the bladder itself, which, according to Fritsch, was caused by an atrophy in the muscular wall of this viscus. Englisch divides these so-called valves into two classes: First, a small prostate

being deeply embedded and dwarfed in its growth; and second, a prostate which has degenerated organically while its position is normal. He gives a history of 1,747 cases which he has examined, and among them found 190 dwarfed glands. In his tabular arrangement, the pathological anatomy is divided into two groups: first, where the valve does not involve any portion of the tissue of the prostate itself, but is simply taken up by a fold of mucous membrane, which he designates "valvula mucosa," or where the mucous membrane and a ring of fibrous tissue is taken up to form what he calls "valvula muscularis." The second group comprises a valvular arrangement formed out of the substance of the prostate itself, which he names "valvula musculo-glandularis." The symptomatology of the small prostate resembles in every detail that of the enlarged prostate, particularly in adults after puberty, where enuresis is the most troublesome symptom we have to deal with. For this morbid condition he recommends the "injections epidurales" of Kathelin, which he has found act in a speedy and effectual manner. He has not met with that success that many other authors record of relieving enuresis by removing the patient to hospital. He has found in several cases, however, that many of them have been relieved by the sectio alta operation and destroying the pseudo-valve. Others have succeeded in the same manner by the sectio perinealis. In cases of atrophy of the prostate arising from senile cachexia or inflammation, he gives very little to encourage the hope of any successful treatment. The cause of the atrophy should be relieved as much as possible by removing all foreign matter, and frequently catheterising to prevent complications arising in the bladder and kidneys.

The Operating Theatres.

GUY'S HOSPITAL.

OPERATION FOR HOUR-GLASS CONSTRICTION OF THE STOMACH.—Mr. ARBUTHNOT LANE operated on a case of constriction of the stomach at some distance from the pyloric orifice, so that the stomach was divided into two parts of unequal size, that forming the cardiac being much larger than that forming the pyloric portion. The patient, a woman, æt. 50, had suffered from symptoms of gastric discomfort for many years, and within the last few years she had been troubled also with vomiting. She had restricted her diet and lost flesh very considerably. Her stomach walls could be felt distinctly, and in the situation of the constriction a hard cicatricial mass could be felt which was attached to the under surface of the liver in the position of the gall-bladder; indeed, this mass had previously been regarded as a contracted gall-bladder which had become adherent to the stomach and had produced the gastric symptoms of which she complained. The front of the stomach was exposed by a vertical incision through the anterior abdominal wall; the stomach was then seen constricted in the manner already described. The constriction was due to the healing of a gastric ulcer whose base had also become attached to the under surface of the liver and gall-bladder. As far as could be judged by the appearance of the cicatrix the ulcer had been a simple one, and there was nothing to suggest any cancerous infection. The aperture of communication between the two portions of the stomach was very small indeed, and only permitted the introduction through it of a slate pencil. A vertical transverse incision was made through the stricture and through the wall of the stomach on either side, so that a large aperture of communication was established between the two portions of the stomach. The edges of the incision were brought together in such a manner as to restore the functions of the stomach completely. Mr. Lane said this case illustrated the difficulty of differentiating between an inflamed gall-bladder attaching and interfering with the lumen and functions of the stomach, and a primary ulceration of the stomach which becomes attached to the gall-bladder and interferes with its function, while it also materially affects the form, utility and function of the stomach. Such conditions, he thought, could be differentiated from one another only by a careful inquiry into the history of the patient and by the skilful employment of one's fingers. The progress made by the patient was excellent. She lost her pain, nausea and sickness, and rapidly put on flesh.

PANCREATIC CYST.—The same surgeon operated upon a case of pancreatic cyst in a woman, æt. about 35. The patient had suffered from a lump in her abdomen for between two and three years. It had interfered very much with her comfort, preventing her from wearing her corsets, producing indigestion and constipation, both of which had required much treatment for their alleviation. At one time she consulted a physician, who informed her that the lump in the left side of her abdomen was produced by the accumulation of fæcal matter in her large bowel, and advised massage and various manipulations, which he himself undertook to apply; in doing this he used much force. She felt the lump subside suddenly during the process, when she was informed she was cured. The so-called cure was followed by much abdominal pain, nausea and tenderness, which lasted for several days. As she did not pass the masses of hard fæces which she was led to suppose had produced the lump, and as the process of cure was followed by so much discomfort, she did not consult that physician again. The lump very soon returned in the same situation and became bigger than it had been before. The large bulk of the tumour was situated on the left of the middle line, extending upwards under the stomach and ribs, backwards into the loin, downwards below the level of the umbilicus, while it projected across the middle line of the abdomen to the right about two fingers' breadth. The lower part of the kidney could be felt on its posterior surface, and the cyst and kidney appeared to be intimately united. A distinct thrill could be felt in the cyst. An incision was made along the outer margin of the erector spinæ, the kidney was displaced inwards, and an incision was made into the bulging cyst in this situation. The contents of the cyst were evacuated and a drainage-tube introduced and fixed in position. From the history of the case it seemed very probable, Mr. Lane said, that the cyst wall had been ruptured in the process of manipulation, and that the fluid had been diffused through the general peritoneal cavity and gradually absorbed. The contents of the cyst which were evacuated at the time of the operation in no way differed from those which are usually present. The diagnosis, he pointed out, lay between pancreatic cyst and hydronephrosis, which involved the pelvis of the kidney only, and left the secreting substance of the organ unaltered.

WE have received the following from the Colonial Office:—"Disquieting reports having appeared in the Press as to an outbreak of yellow fever in Jamaica, the Governor of that Colony has telegraphed that since the death of an officer from this disease, which he reported on November 19th last, no case has occurred, and that the state of health in the island is most satisfactory."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 13, 1904.

PHARMACOPŒIA REVISION.

ONE of the important events of the past year was the publication by the Pharmacopœia Committee of the General Medical Council of a "Digest of Researches and Criticisms," prepared for them by William Chattaway, F.I.C., Superintendent of the Society of Apothecaries. The "Digest," as some of our readers are doubtless aware, covers the various researches and criticisms that have appeared between the years 1899 and 1902. Most of the quotations are taken from the *Pharmaceutical Journal*, the *Chemist and Druggist*, the *British and Colonial Druggist*, and the *American Journal of Pharmacy*. Another source of information is the valuable series of investigations recently carried out in the Research Laboratories of the Pharmaceutical Society at the instance of the General Medical Council. In this case, however, full details are not supplied, as they had already been reported direct to the Council. The "Digest" comprises some seventy closely-printed pages of weighty matter, and so far as we have examined it, contains brief yet adequate accounts of almost every criticism or research bearing on the varied collection of substances contained in the "Pharmacopœia." The importance of this work to the medical profession can hardly be over-estimated, when we take into consideration the fact that the whole of its progressiveness must depend ultimately on the proper appreciation of fresh facts. On this point Mr. Chattaway says: "I think it is clear that of the large number of researches published many new facts may be taken as fairly well established, and available for use in a new edition of the 'British Pharmacopœia.' On the other hand, it is equally clear that there are many cases where revision and confirmation are desirable before new processes can be regarded as sufficiently well established to warrant their official recognition." This comment, wide though it be, will, we feel confident, be found fully justified on a careful perusal of the "Digest," in which the criticisms dealing with the botany of the "Pharmacopœia" are but few, as might have been expected, seeing that such well-equipped experts as Mr. E. Morell Holmes and Sir William Thiselton-Dyer were engaged in advising the Council on these points. The "Digest" contains suggestions by many well-known pharmacists for improvements in the manufacture of many valuable preparations, as well as for the improvement of methods of assay and tests for impurities. It forms, again, a handy compendium of reference to the pharmaceutical progress during the past three years, and from that point of view should be of considerable use to pharmacists generally. We understand that it is obtainable by post from the offices of the General Medical Council for a merely nominal sum. It seems a pity that a more durable style of binding was not adopted, as the copy which we have received is bound in a thin paper cover which would hardly survive even a moderate amount of use. We congratulate the compiler of the "Digest," Mr. C. G. Moor, on the manner in which he has carried out his task, and believe that the facts he has collected will prove of great value to the Pharmacopœia Committee when they have before them the important question of preparing a new edition of our national text-book of pharmacological lore. It is an open secret that the "Digest" contains many references to his standard work on the "Purity of Foods and Drugs."

THE CONSUMPTIVE AT HOME.

WHILE the immense value of the sanatorium and other forms of open-air treatment for consumption is daily becoming more fully recognised, it must be remembered that, as yet, these methods are available only for a comparatively small proportion of the total number of cases of the disease. We have not yet arrived at the time when municipal sanatoria will be provided for the poorer class of consumptives inhabiting their respective boroughs, but there are indications that this is the direction in which the therapeutic progress in pulmonary phthisis will ultimately be made. In the meantime, it is obvious that the immense majority of tuberculous patients must be treated in their own homes, under circumstances which must often militate considerably against restoration of the lung-tissue. It is little to be wondered at, sometimes, that such patients, seeing the impossibility of carrying out the directions of the physician with regard to the hygienic arrangement of the bedroom, the necessity for suitable and sufficient nourishment, and other details in the management of their cases, are apt to lose heart in themselves and, what is equally bad, confidence in their medical attendant, and relax the very precautions they had at first promised faithfully to observe. How is it possible to treat tuberculosis efficiently under conditions of extreme poverty, gross overcrowding, or bad sanitary conditions? The problem, indeed, seems hard to solve, and yet a good deal may be accomplished by the dissemination of knowledge respecting the need for the

disinfection of sputa, properly lighted and ventilated rooms, and strict cleanliness. Professor William Osler has recently called attention to this important aspect of the tuberculosis question, and has laid stress upon three essential points in the treatment of the consumptive at home. In the first place, the necessity for an earlier recognition of the disease is urged, and, provided that the patient will only seek medical advice before definite pulmonary symptoms have supervened, it should not be difficult after a thorough systematic physical examination to enlist the intelligence of the patient himself in his condition and invite his co-operation in battling with the tendency to the disease, and in overcoming the first onslaught of the tubercle bacillus. When physical signs have appeared, Professor Osler pleads for a more "masterful management" of the early cases. It is here that real practical difficulties arise, for, however willing and anxious the patient may be to subdue the affection, neither he nor his friends may show much disposition to upset the arrangements of the home by providing freer ventilation than that to which they were formerly accustomed. Once the patient's confidence is gained—and this is a most important point—the hope of recovery will, in the majority of cases, prove a sufficient stimulus by which he may overcome objections and other temporary obstacles in the way of the successful carrying out of the plan of treatment. Another *sine quâ non* in the home-cure of consumption is persistence, without which any system of therapeutics will fail. In only too many instances is it seen that the good effect wrought by treatment is undone at night by sleeping in stuffy and overcrowded rooms. Intermittence, whether nightly or at longer intervals, must be rigorously guarded against, and this more especially if any signs of improvement are manifest. If due regard be paid to these essentials in the home-treatment of tuberculosis, the lot of the consumptive who, from lack of accommodation or means, is deprived of the advantages of sanatorium life should be rendered more endurable and his outlook somewhat brighter.

SCIENTIFIC AND MEDICAL EDUCATION.

IT is natural that there should be considerable disagreement on the question of the proper place of scientific training in the curriculum of a medical student. There are certain sciences which by general consent must form a part of any proper course of medical education, and others whose standing in that connection is more or less debatable. In the first class must be placed such branches of study as anatomy, physiology, and pathology, whose main truths form the basis of any rational art of surgery or medicine. In the second, one may mention what are often called the preliminary medical sciences, such as biology, botany, and physics. No question regarding the professional course has caused so much difficulty as that of the importance to be attached to these subjects, and the General Medical Council, by its dealings with the Royal Colleges, has allowed it to appear that considerable individuality of action by the different licensing bodies will be tolerated. With this subject, however, it is not our intention to deal just now, but rather with the position in the medical curriculum of what we may call the essential medical sciences, and, in particular, anatomy and physiology. This matter has recently been considerably discussed in medical circles, and especially in the Universities of Dublin and Edinburgh. It appears that in both these schools it is now the custom for students to begin their attendance at hospital in the same winter as they begin to dissect and to attend lectures in physiology. In both places, as might be expected, hostile criticism is heard. It will be remembered that in his opening address to the Yorkshire College Medical Department, Professor Schäfer held up the Edinburgh School as the drunken helot to modern medical Sparta—the example of how things ought not to be done. Instead of starting the study of medicine at the same time as he starts that of physiology and anatomy, Dr. Schäfer thinks that the student should complete his study of the latter subjects before the former is begun, and he emphasises the crudeness which necessarily results from attempting both branches together. We think that there is often a tendency to over-estimate the educational value of a purely scientific training, and, in consequence, to neglect the humaner studies, and, indeed, we agree with one of Professor Schäfer's severest critics that "there is no more narrow-minded man than he whose education has been exclusively scientific. The years before the medical curriculum is commenced should, therefore, in an ideal course, be devoted to the broadening of the mind by extra-scientific studies, and especially by the study of such subjects as philosophy." Nevertheless, we think that Professor Schäfer's main contention is right, and that any attempt to learn medical and surgical practice without a proper grounding in anatomy and physiology must result, if it results in anything but the accumulation of an undigested mass of useless facts, in the crudest empiricism. The student who has never dissected can learn nothing from watching a surgical operation, or from hearing a clinique on, let us say, pneumonia. To him, the lung, the bronchi, the alveoli, and the pleura are only names, and quite meaningless. Even the most painstaking teacher cannot stop to explain every technical term he uses, and in the actual condition of affairs at Dublin and Edinburgh to-day he would not only have to do this, but to spend his time in elementary explanations of the simplest anatomical and physiological facts, if the first-year student is to learn anything from his teaching. The result at present is that the average student soon finds he is not learning anything of value and he gets into the habit of neglecting hospital attendance, or, on the other hand, if the wards interest him, he neglects his dissecting. The cessation of attending hospital would be in itself innocuous, were it not that the habit thus formed is likely to persist during the later years of the student's course, when hospital

work should be the one important thing. We fear it is impossible to prevent some overlapping of the work in the wards and in the dissecting-room, but at least one winter should be kept free from hospital interruption. At the same time we think it only fair to Dublin and Edinburgh to point out that there is much to be learnt from an early experience—what was described in Albert Smith's days as "walking the hospitals." In that way there is an everyday acquaintance to be acquired with the features of disease that is often wanting in the highly qualified and theoretically perfect product of modern medical education. It seems not improbable that the pendulum has swung too far in the direction of theoretical as against practical education.

Notes on Current Topics.

Historical Medical Exhibition.

AN exhibition of a novel and attractive kind is announced to take place shortly in London. It is nothing less than a comprehensive historical exhibition of rare and curious objects relating to medicine, chemistry, pharmacy, and the allied sciences bearing upon "the science and art of healing throughout the ages." Messrs. Burroughs Wellcome and Company have organised this most interesting project as an appropriate means of celebrating the lapse of a quarter of a century since the foundation of their firm. They announce that the exhibition will be strictly professional and scientific in character, and they ask the co-operation of medical men throughout the United Kingdom. It is with great pleasure that we draw the attention of our readers to the matter, and we cordially invite them to intimate either to the Editor of THE MEDICAL PRESS AND CIRCULAR or to Messrs. Burroughs Wellcome and Company direct their willingness to loan any objects of interest, such as interesting old books, manuscripts, ancient medical relics, surgical instruments, or, in short, anything rare and curious appertaining to things medical. In the rush and hurry of modern professional life it is well to be reminded that we of to-day depend to no small extent for our knowledge upon the evolution of a buried past. A survey of history, moreover, enforces the lesson that the underlying principles of medicine and surgery are eternal, however much the surface eddies of form and fashion may change.

Koch's Birthday.

THE sixtieth anniversary of the birthday of the discoverer of the tubercle bacillus is being celebrated in Germany by the issue of a festival number of the *Deutsche medizinische Wochenschrift*, to which many of the leading pathologists of this country and the Continent are contributing articles. The public celebration will have to be postponed, as the protagonist himself is away in Rhodesia, working for the second time at rinderpest for the Colonial Government, and even on his return, with a characteristic dislike of fuss and pomp, he has insisted that only past and present assistants shall be present at the gathering. It is interesting now that the great savant's name is again to the fore to note that there are indications that he has modified the opinion that startled the world so much when he enunciated it at the Tuberculosis Congress three years ago. Till then it had been actively assumed that human and bovine tuberculosis were both due to the same species of tubercle bacillus, and many important regulations had been founded on that assumption. When Koch, himself the sponsor of the tubercle bacillus, announced that the diseases were due to different organisms, the ground under the feet of hygienists seemed to be cut away. It is not too much to say that in no country except Germany has this view been accepted, and all subsequent work in this country, especially Professor Hamilton's, has tended to negative Koch's dictum. A book on the prevention of consumption just published has been revised and criticised by Koch, who, although not the author of the work, has thus made himself responsible for the opinions expressed in it. The section dealing with the communicability of bovine tuberculosis to man discusses the question very fully, and concludes that the question is still *sub judice*, and not, as one had hitherto supposed, *une chose jugée*—from Koch's point of view. For those of us who admire the great work that he has done for bacteriology, but who were not prepared to follow him in his latest developments, this modification of Koch's view will be very acceptable.

Massage of the Heart.

THE sensational feat accomplished by Mr. Arbuthnot Lane in restoring animation by massage of the heart in a patient who had apparently died during an operation for appendicitis performed under ether is still fresh in the minds of those who read of it. Several Continental surgeons have attempted massage of the heart under similar circumstances; they have generally opened the thorax and pericardium and squeezed the heart with the hand. None of these have been successful, and Batelli, who has tried the same manœuvre on dogs, has not had encouraging results, for all his animals died within a few days, even if their immediate resuscitation was accomplished. Boucart has been making further experiments on dogs, but his method is to massage the heart, not directly through a wound in the chest, but mediately through a laparotomy incision. The animals were anæsthetised with chloroform till syncope occurred; then tracheotomy was performed, and artificial respiration begun. A median incision was promptly made through the abdominal walls, the hand introduced and slipped up over the stomach, and the heart defined through the relaxed diaphragm. The fingers then seized the heart and gentle rhythmical compression was made till spontaneous contractions of the organ itself were felt to be setting in. The heart was apt to slip up into the chest during the manipulations, and when this occurred care

had to be exercised not to squeeze the bronchi and interfere with respiration. Boucart's results were decidedly encouraging, for of four dogs on which he experimented one recovered completely after having been dead apparently for ten minutes. Another recovered, but died the next day from œdema of the lungs, due probably to liquid chloroform being inhaled by mistake; a third regained cardiac motion, but respiratory movements did not follow; and a fourth died through the heart compressing the bronchi, during inversion of the animal. Considering the number of deaths annually from chloroform syncope, and the poverty of our resources in treating patients thus intoxicated, sub-diaphragmatic heart massage, heroic though it sound, may be of distinct service as a last resource.

Bed Books.

AN interesting discussion is now proceeding in a contemporary on the merits and perils of reading in bed. It is a matter on which a medical adviser is not infrequently consulted. As with most matters concerned with individual needs much discretion and a wise discrimination is necessary before judicious direction can be safely given. Bed books are often bad books, but to condemn a habit before studying all the conditions which have given rise to its establishment, and the various circumstances under which it is conducted, is both unwise and unscientific. To many, reading in bed comes as a solace and comfort after the turmoils of the day, and in the land of fiction many a weary, worried struggler finds rest and restoration. But to not a few the nocturnal novel is pernicious and capable of working much damage. Wisely selected reading may serve as a pleasing soporific and desirable sedative, but a reckless trespass into certain types of so-called literature is productive of nothing but evil. The secret of success in this, as in so many other matters, must depend upon our knowledge of action and re-action. The man who is not absolutely "fit" both in mind and in body had better consult his physician if he wishes either to commence or to continue reading in bed.

The Curse of Corsets.

DRESS is the charity which covereth multiple grievous deficiencies in the feminine form that mere man in his ignorance once designated divine. We do not venture on such a statement as the result of our own experience or experiment. It is the verdict of Dr. Arabella Kenealy, clearly drafted in the serious pages of this month's *Nineteenth Century*. All minds are now being directed to a scientific study of influences making for racial deterioration. The "lady medical" finds that decadence originates in "the curse of corsets." "The average woman, clothed as fashion clothes her, presents, I confess, an exterior pleasing to our artificial and acquired tastes. Unclothed—alas! She is that to make the physiologist and artist weep." The average physiologist, as far as we are acquainted with him, is not given to excessive lachrymal secretion, and even the fashionable ladies' physician does not usually display tearful tendencies. We can only imagine that Dr. Kenealy is referring to physiologists and artists of her own sex, and, concerning such, ignorance is doubtless bliss. We fear but little good will result from such extravagant presentations as that to which we have felt it desirable to draw attention. The abuse of the corset is only too prevalent, and in the initiation of many morbid conditions it probably plays an important part, and certainly often does much to hamper physical development. But in spite of the lachrymation of female physiologists, it is well to remember that both experience and experiment afford evidence that a wise use of corsets is sometimes advantageous. Tight-lacing stands condemned on all counts, but there are sound physiological reasons for the rational adoption of some form of thoracico-abdominal support.

Camps for the Tuberculous.

THE New York Board of Health has given a good example in regard to the provision of accommodation for the out-door treatment of the victims of tuberculosis. A tract of land, of ample dimensions, at a reasonable distance from the City and other inhabited places, and at a certain altitude, has been selected and on it are to be erected a number of tents, furnished with the strictly necessary furniture and even something more. It is contemplated that each tent will accommodate two or three persons, but single tents will be available for persons in a position to pay a small additional sum. We have over and over again insisted on the fact that this plan is the only one that will enable us to bring the open-air treatment within reach of the tuberculous masses. The costly institutions which have so far been the rage are filled for the most part with persons whose claims to admission consist merely in their pitiable condition—those, in fact, for whom the open-air or any other treatment can do little or nothing. These tents can be fitted up for about £25 each, and are easily moved as occasion may require. There is no reason, not even that of expense, why every district, rural as well as urban, should not have its open-air camp. If the expense be kept down, such a camp might even be made to cover its cost of maintenance. Officialism appears to be wedded to bricks and mortar, but the system will have to be modified under penalty of the method of treatment falling into discredit.

Dunbar's Antitoxin in Hay Fever.

WHEN Professor Dunbar intimated that he believed this distressing complaint was due, not, as had been previously supposed, to the mechanical irritation of pollen from plants, but to an actual toxin resident in the pollen-grains, it was hoped that the antitoxic serum he presented as the result of his experiments would inaugurate a new era in the treatment of this refractory disease. The early trials of the serum in this country by Sir Felix Semon were decidedly hopeful. Fuller

trials did not bear out the most sanguine expectations formed, but now that the results of last summer's experiments with the serum on both sides of the Atlantic have been published there is good reason for the belief that a distinctly hopeful direction has been taken by Dunbar's departure. Dr. McBride in Scotland has reported several cases which gave similar results to those of Dunbar and Semon, and the suggestion is that all are not successful because the various particles causing the catarrh act by virtue of different toxins. If this be so it is not to be expected that the same antitoxin will be successful in each. Dr. McCoy, in the *New York Medical Journal*, publishes fifteen cases treated with satisfactory results, six of them being detailed in full. McCoy treated his cases by applying the serum with a pipette to the conjunctival mucous membrane and to the nasal passages. Quite small doses, one to four drops, were instilled several times a day and the effect was immediate and complete. The diagnosis was fully established before commencing the treatment, and none but patients who suffered periodically were selected for trial. It is to be hoped that larger quantities of the serum may be available before next spring so that by extension of the experiments some definite decision may be arrived at.

"Homocea, Limited."

IT is evident that our much-advertised friend, "Homocea," however much it may have succeeded in "touching the spot," has not succeeded in at the same time touching the almighty dollar in quite the manner expected by its proprietors and shareholders. The history of the company—"Homocea, Limited"—is a curious one. In 1897 it purchased the patents and trade marks of "Homocea" for the sum of £141,000, a sum which, according to the company's counsel, was "a great deal too high." In 1897, the company paid a dividend on their preference shares, but since then have paid no dividend of any kind. The sole present assets of the company are the aforesaid trade marks and patents, and the goodwill of the business, and as these do not appear to be at the present time very negotiable articles, the wisdom of reducing the capital from a quarter of a million to £60,000 has become evident. Accordingly, the company in December last presented a petition for the sanction of the Court to the proposed reduction. The learned judge had apparently no difficulty in deciding that the above-mentioned assets do not represent value for a quarter of a million, and sanctioned the reduction. We cannot say that we view the tribulations of such companies with sympathetic eyes, nor should we greatly grieve if other similar companies followed a like course. The "Homocea" shareholders must have known when they purchased shares that the business by which they hoped to earn a dividend was one which throve on the credulity of the times, and if they find that that credulity leads people into another shop than theirs they cannot complain. We notice that there is at present an arrear of dividend to the preference shareholders amounting to over £19,000, and if these unfortunate people ever see their money we shall be much surprised. They, at any rate, received one dividend, the ordinary shareholders never received any.

A Forgotten Physician.

IT is seldom remembered that the originator of the "Higher Criticism" of the Hebrew Scriptures, and thereafter of "Higher Criticism" in general, was a professor of medicine. Jean Astruc, a man of much distinction in his time, was born in 1684, and eventually held chairs at Toulouse, at Montpellier, and at Paris. He was a man of wide learning, both in the medical sciences and in letters, and as a teacher he had a European reputation. A voluminous writer, his most important book in the sight of his contemporaries, was entitled "*De morbis venereis libri sex*," which enjoyed great vogue and was translated into English. The apparently inconspicuous book, but for which Astruc would long ago have been forgotten, is a small monograph which was probably regarded by its author as a mere bagatelle. The "*Conjectures sur les mémoires qui ont servis à Moïse pour écrire la Genèse*" is an epoch-making work in the history of literary criticism, and is so merely by the clue which served Astruc to distinguish one author from another. In certain passages in the Book of Genesis, and particularly in the account of the Creation in the first two chapters, the Deity is described as *Elohim*, while in others the word *Johveh* is used. The transition from one passage to the other is always abrupt, and Astruc pointed out the strong probability that they were written by different hands. It is beyond our sphere to discuss questions of literary criticism, but it is interesting to note that the sole originator of what is rightly called scientific criticism was himself a medical man, and a scientific writer of no small repute. At the same time it is passing curious that the pioneer in such a subject should have been, not a scholar, but a specialist in venereal disease.

Compressed-Air Illness.

THE affection which goes by the name of caisson-disease is, like divers' paralysis, seen in workers under conditions of greatly increased atmospheric pressure. The most characteristic symptoms are those of dyspnœa, vertigo, pains in the joints, cramps, and a rapid pulse. The venous blood obtained by venesection has been observed to be arterial in colour. But, since these morbid phenomena invariably appear when the men return to the ordinary pressure of the air,—*i.e.*, after decompression, the disease might, with propriety, be known by the name of decompressed-air illness. The pathology of the condition was thought, at one time, to be due to mechanical congestion of the central nervous system, and especially of the spinal cord. This theory has been disproved by Paul Bert, and, more recently, by Drs. Leonard Hill and J. J. R. Macleod (*a*). These observers have found that no change in the mean

(*a*) *Journal of Hygiene*. October, 1903.

blood pressure occurred during compression of air in a chloralised rabbit, nor in a frog's web or a bat's wing. The conclusions arrived at by modern research are that caisson-sickness is due to the escape of bubbles of gas from the blood vessels and body-tissues on decompression. The gases of the atmosphere, having been absorbed into the blood, are again given up when the pressure under which they have been dissolved is withdrawn. The tissues under these circumstances may be compared to an open soda-water bottle in a state of effervescence. The different symptoms produced depend upon the varying localities of these air-emboli. It is found that young men generally escape the disease on account of the elasticity of their tissues and greater facilities for collateral circulation. Drs. Hill and Macleod consider that the length of the period of decompression is one of the most important factors in preventing this troublesome malady. They believe that by working in short shifts of not longer than four hours and by allowing sufficient time, about two hours, for decompression, the disease may be avoided altogether.

Poisoning by Honey.

FROM a case narrated in the *Guy's Hospital Gazette*, it would appear that honey is not always the delectable article which it is supposed to be. Shortly after partaking of some fresh country honey a lady was affected with urticarial symptoms, the larynx becoming œdematous and the respirations hurried. Fortunately, the condition cleared up after a prompt purgative. From time to time there have been reported instances of severe poisoning from the consumption of honey, the fact of which was known to and described by Xenophon, who relates how that certain Greek soldiers were seized with vomiting and sickness after partaking freely of the honey gathered in the neighbourhood of Trebizonde. In a paper read by Dr. J. C. Thresh (*a*) before the Pharmaceutical Society, some information was given with regard to the nature of the poison. According to Dr. Stockman, of Glasgow, who examined an ethereal extract of this honey physiologically, the active substance was stated to be "a narcotic poison, acting very markedly on the respiratory centre." In other cases, gelsemium has been found impregnating the honey, the consumption of which has given rise to all the symptoms of poisoning by that drug, such as giddiness, cardiac weakness, and temporary amaurosis. Death has even occurred under these circumstances, though, happily, such an event is extremely rare. Severe pruritus has also been observed to follow the eating of honey culminating in the outbreak of an erythematous or urticarial eruption. The obvious explanation of these untoward manifestations is that the particular sample of honey has been gathered by the bee from a poisonous flowering plant, for, notwithstanding the gaudiness of the bloom and its richness in the syrupy liquid, the melliferous insect can hardly be expected, even by M. Maeterlinck, to possess sufficient powers of discrimination always to abstain from gathering its spoil from such sources. Only rarely, however, does it err in this respect.

(*a*) *Brit. Med. Journ.*, ii., 1887, p. 1,168.

The Significance of Albumoses.

THE nature, plurality, and separation of the intermediate substances between the albumins, on the one hand, and the peptones, on the other, form no small corollary to the chapter in the physiology of digestion. When one or more of these bodies appears in the urine there is an added interest attaching to it from the clinical standpoint. That variety known as the albumose of Bence-Jones, first described by that observer in 1848, and possessing the characteristic heat-reaction, is now definitely associated with a rare affection of the bone-marrow which bears the name of myelopathic albumosuria (Bradshaw). The albumosuria described by Professor Teissier, of Lyons, a year ago, is met with especially in severe forms of chronic nephritis, and this kind of albumose is soluble in nitric acid. In addition to these two varieties, M. Piéry (*a*), of Lyons, has recently described a third, the clinical significance of which is less definite, as it is seen in very diverse pathological conditions. It can be recognised by a special test, that of Jacquemet, which consists of first getting rid of any albumin which may be present by acidification, boiling, and filtration, and then, when cool, of mixing the urine with one-third of its volume of sulphuric ether. This is shaken, and the tube is then left for a quarter of an hour in the vertical position, when, if this form of albumose be present, a gelatiniform clot, like a plug, will appear upon the surface of the liquid. This "ether-albumose" is found in the urine of many normal individuals, and also in most of the infectious diseases, as well as in chronic nephritis. Seeing that this body is present under such varied conditions, its true pathological significance has yet to be determined.

The Surgery of Typhoid Perforation.

ELSEWHERE in our columns (page 29) we publish an account of a most interesting report of operation for perforation of the bowel in enteric fever. The case is both suggestive and instructive in the highest degree. The patient, a youth of twenty-one years, was admitted to the Cork Street Fever Hospital in Dublin, under Dr. H. C. Drury, suffering from a mild attack of enteric fever, apparently of twelve days' duration, but in all probability the disease had been going on for three weeks or more. One morning he complained of severe pain in the abdomen, and it was evident that perforation of the bowel had taken place. Seven and a half hours after the occurrence of that accident he was operated upon by Mr. William Taylor. At that time the patient was in a state of collapse, and apparently dying. A small perforated ulcer was sutured, another ulcer on the point of ulceration also sewn up, the intestines cleansed, and the wound closed. On the fourth day after operation the pulse had dropped from

(*a*) *Lyon Medicale* October 11th, 1903.

150 to 100. At the end of seven days, temperature had dropped to normal. Twenty-eight days after operation pain commenced and the patient gradually grew worse, with constipation, so that next day a second operation was performed. Extensive adhesions were found, and the gut was bent at a sharp angle. The patient gradually sank after the second operation. The results of this case are brilliant and encouraging, for clearly the patient recovered from the original operation performed for relief of typhoid perforation under the most desperate and unfavourable circumstances that could well be conceived.

Fæcal Accumulation.

MOST physicians of experience have, at one time or another, been astonished at the degree of fæcal accumulation which may occur without the patient paying any attention to the condition. In some cases, most commonly in chlorotic young women, the patient denies that there has been any constipation, and can hardly be persuaded that there is a mass of fæces in the intestine. On suitable treatment, however, she is very often startled at the discovery of the enormous masses which were in reality present. Few cases of fæcal accumulation can, however, parallel that recently recorded in one of our contemporaries. The patient, an elderly man, showed such swelling of the abdomen that the girth was increased from a normal thirty-two by no less than twenty inches, and the percussion note over the entire belly was dull. The constitutional symptoms were severe—high temperature, pulse-rate, rigors. Nevertheless, defæcation had taken place regularly once or twice a day. After treatment by enemata and castor oil, the temperature and pulse-rate diminished, and in the course of a week as many as 171 large stools were passed. As in most such cases, all symptoms of auto-intoxication disappeared when the intestine was thoroughly cleared of its contents.

A National Laboratory of Hygiene.

THOSE of us who are continually pressing for more open and liberal State recognition of scientific research and investigation of health problems will feel our mouths water when we read of the beautiful National Laboratory of Hygiene which is being built at Washington, and is now nearly completed. This laboratory was provided for by a special Act of Congress, and will be under the Department of the United States Public Health and Marine Hospital Service. It will be directly controlled by an advisory board, consisting of the Director of the Laboratory, five members appointed by the Surgeon-General of the Public Health and Marine Hospital Service, and three specialists nominated by the Army, Navy, and Bureau of Animal Industry. Hygiene, though the prime object of the laboratory, will not be exclusively dealt with, for there are to be departments for making investigations in pathology and pharmacology, as well as in chemistry and bacteriology. Each of these departments is to be under the management of a chief who has special knowledge and skill in the work that the department investigates, but he is always to keep in view the bearing of the researches on public health problems. The results arrived at are to be published periodically in bulletins, and these should contain material of the greatest value and importance, as under such direction systematic, as opposed to sporadic, effort can be organised and moulded to the same ends. One of the principal duties of the laboratory will be to manufacture anti-diphtheritic serum of guaranteed efficacy, and the direction will be responsible for the supervision of the antitoxic sera produced by private firms. In America many firms produce low-grade and unreliable sera—a curse we are fortunately free from in this country—and great discredit is brought on serum-therapy thereby. In the future this unsatisfactory condition of things will be impossible. Are we, who have a Prime Minister who openly sympathises with our own professional aspirations, to be the last nation to have State-supported research laboratories ?

Extract of Meat and Yeast.

A LURID light was shed on some brands of meat extract at Liverpool Police Court. David Pearson, trading as the Anglo-American Food Company, was summoned for selling extract of beef containing about half its weight of yeast extract. Mr. Trubshaw (who prosecuted on behalf of the Liverpool Corporation) said there was a label on the bottle intimating that the contents were extract of beef, consisting solely of the juice of the finest beef ; but upon an analysis the sample was found to contain half its weight in yeast extract, a substance imported from Germany. Defendant was fined £5 and £10 10s. costs. This conviction is of special interest to THE MEDICAL PRESS AND CIRCULAR, as the fraudulent substitution of yeast for meat extract was first pointed out in the columns of this journal.

THE South African Medical Congress has initiated a movement for the formation of an association for the prevention of consumption and other forms of tuberculosis. The opinion has been expressed in Natal that consumptives in an advanced stage of the disease should be prevented from entering South Africa, and it is stated that twenty years ago consumption was practically unknown in that country, but has now become a serious danger to the community. Protection of the kind suggested merits serious consideration.

THE Court of Governors of Christ's Hospital on Wednesday approved unanimously the recommendations of the Site Committee in favour of disposing of the remaining part of the site to the Government for the purpose of the Post Office. This decision means that Christ's Hospital will receive £23,000 a year in perpetuity. It also means that St. Bartholomew's will have to look elsewhere for an extension of its ground area.

IT is announced that a new Pasteur Institute has been established at New Orleans, where the anti-rabic treatment will be carried out without any expense to the patients. The success of the original Paris Institute renders the establishment of new centres of treatment highly desirable.

THERE were twenty-six sufferers from small-pox remaining under treatment on Friday noon at the Long Reach Small-pox Hospital, Dartford. This amount of infection points to a persistence of the disease in London that must arouse a certain amount of apprehension.

THE Food Test Commission, appointed by the United States Government, reports that the use of salicylic acid in food is seriously injurious to health. The importance of this conclusion is obvious and universal.

THE death is announced at Munich on Tuesday the 5th inst., of Professor Karl von Zittel, the famous palæontologist and author of the well-known "Manual of Palæontology."

IN the recent rout of the Mullah by General Egerton in Somaliland, we regret to announce the death of a promising young officer, Lieutenant Joseph Raboteau Welland, M.B., who became lieutenant in the Royal Army Medical Corps in June, 1891, and was attached to the King's African Rifles. He had not been previously on active service.

PERSONAL.

DR. HERBERT OWEN TAYLOR was presented last week with a handsome testimonial from the Nottingham Police Force, to which he has acted as surgeon for the past thirty years.

THE Lambeth Guardians last week, out of fifty-five applicants from whom to select a medical officer for their schools at West Norwood, chose a Carmarthenshire lady, Miss N. V. Johnson, the only lady candidate.

THE late Sir Robert Martin Craven, F.R.C.S., at one time Sheriff of Hull and President of the Central Hull Conservative Association, has left property of the gross value of £40,492, including net personalty estimated at £23,335.

MR. H. C. SHANN, M.R.C.S.Eng., L.R.C.P.Edin., who recently retired from his position as medical officer of the York Union Workhouse, has been presented by the officials of that institution with a handsome testimonial.

MR. ALFRED JAMES BARKER, M.D. St. And., late of Beaulieu Villas, Green Lanes, N., who has recently retired from practice on account of advancing age, has been presented with an album and purse by his numerous patients and friends.

THE opening clinical lecture of the spring session at the North London Post-Graduate College, Tottenham Hospital, will be given by Dr. T. Gilbart Smith on January 14th, at 4.30 p.m. The subject will be "Certain Points in the Diagnosis of Fluid in the Chest."

DR. E. SYMES-THOMPSON, Gresham Professor of Medicine, will deliver a course of four lectures at Gresham College, Basinghall Street, London, on "The Evolution of Plants, Animals and Man." The first lecture will be delivered on the 19th inst., at 6 p.m. the course being free.

THE course of lectures at the Hospital for Consumption and Diseases of the Chest for 1904 will be opened by Sir Richard Douglas Powell, Bart, M.D., by an address on foreign bodies in the bronchi, on January 27th, at four p.m. The lectures are free to qualified practitioners and to students of medicine.

THE second Hunterian Society's lecture will be delivered by Mr. Anthony Bowlby, C.M.G., on Wednesday night, at 8.30 p.m. The subject will be "Pain: its Clinical Significance and Importance in Diagnosis." All members of the medical profession are invited to attend.

DR. MENDES DE LEON, of Amsterdam, will read a paper before the British Gynæcological Society tomorrow (Thursday) evening, at 8 p.m., to which meeting all practitioners are cordially invited. The subject of the paper will be, "A Hitherto not Sufficiently Recognised Source of Infection during Operations."

DR. WILLIAM C. NEVILLE, F.R.C.P.I., formerly assistant-physician, Coombe Hospital, and Lecturer in Midwifery, Carmichael Schhool of Medicine, has been appointed Pathologist to the Rotunda Hospital. Dr. Neville is well known in the obstetrical world as the inventor of the axis-traction forceps which bears his name.

IN the presence of a large assembly at St. Augustine's Church on Saturday the 9th instant, Mr. Harold Spender was married to Miss Violet Hilda Schuster, only daughter of Dr. Ernest Schuster and Mrs. Schuster of Harrington Gardens. Mr. Spender is a well known editor of London, and son of the late Dr. Kent Spender, of Bath.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

BELFAST.

THE MILK SUPPLY.—The question of pure milk and how to obtain it has been brought prominently before the public by the very generous offer made by Dr. and Mrs. Henry O'Neill to the Public Health Committee of the Corporation. The offer was one of £300 to encourage the establishment of a milk sterilisation depôt in Belfast, but it had to be declined, as the Corporation lack the necessary legal power to establish such a depôt. An able article in the *Northern Whig* advocates the adoption of "measures by which the milk may be produced in such a way that it may be used with confidence by the public without any necessity for its being pasteurised or sterilised." The measures proposed are (1) regular inspection of the cows, with testing for tubercle; (2) sanitary byres; (3) cleanliness in all departments; (4) regular medical examination of the milkers and other dairy workers; (5) rapid cooling of the milk; (6) delivery of the milk in sealed cans or bottles. The dairy of Mr. Sonensen, of York, who has proved that a business worked on these lines can be a thorough commercial success, is described at length. It is to be hoped Belfast enterprise will take the hint.

SMALL-POX.—A case of small-pox occurred early last week in Newtownards, the patient being a young man from Glasgow visiting co. Down on his holidays. Two more cases occurred later in the week in Belfast, and it is to be feared that others will follow, as one of the cases was discovered in a crowded house in one of the worst slums of the city, where the patient (a child) had been ill some days.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Robert Lee's second contribution does not, to put it mildly, carry the question much further, whilst it unfortunately is painfully suggestive of the attitude of one who is willing to wound and yet afraid to strike. The keynote of the letter is to be found in the sentence: "Personally, I dislike and distrust vivisection as a method of research." This is an interesting confession, but hardly of any value save to the mill of the anti-vivisection fanatic, where a mere empty husk to grind is welcomed in the absence of grist of any solid value. Harvey, the Hunters, Pasteur, Charcot, says Dr. Lee, were all honourable, humane physiologists; are the men now living who are devoting their lives to *scientific* investigation much inferior in character to their great dead masters, and are they less convinced of the necessity for experimentation on animals in the pursuit of new truths?

Dr. Lee asks practitioners what they have learnt from vivisection themselves, from their own experiments first, and from what they have seen others do next? Practitioners are not called upon, and virtually never do perform experiments upon animals; they need to learn, and do learn only from the work of others; research directed to results of importance absorbs the whole energy of the worker; no practitioner attempts it. As to what a practitioner may have learnt from what he has seen others do, this must depend upon the time spent in laboratories and the experiments there observed. A year might be passed in such observation in one direction without any result to record, except, perhaps, some of negative quality; but it does not at all follow that mere negative results were valueless, or that valuable positive results had not been achieved elsewhere. What can be the value of any practitioner's evidence in this direction is hard to guess, but one must suppose it is quite clear to Dr. Robert Lee.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

January 7th, 1904.

Obituary.

MR. JAMES BOWYER BAKER.

THE death is announced, in his seventy-first year, in London, of Mr. James Bowyer Baker, Brigade Surgeon, retired, of the Army Medical Staff. The fourth son of the late Rev. W. L. Baker, M.A., of Hargrave, Northamptonshire, he received his professional education at Guy's Hospital, and being admitted a member of the Royal College of Surgeons, England, in 1854, he joined the Army Medical Service in May, 1857, and served with the expeditionary force in the North of China in 1860, for which he had the medal. He was placed on the retired list in 1882.

DR. R. M. TAGERT.

WE regret to announce the death of Dr. R. M. Tagert, at his residence, Kingstown, on December 27th, He took the degree of M.D. of the University of Glasgow in 1837 and in 1845 became F.R.C.S. He was formerly medical officer to the union workhouse and dispensary at Carrickmacross, also to Farney Baronial Fever and General Hospital. He was the oldest medical man in the county of Dublin, where he had secured universal respect and esteem. At the time of his decease he had reached the patriarchal age of ninety-one years.

MR. R. V. FLETCHER.

WITH regret we record the death of Mr. R. V. Fletcher, resident medical superintendent of the District Asylum, Ballinasloe, Galway, on December 17th, 1903, after a lingering illness following an attack of influenza contracted last winter. The deceased was born in the year 1840, and received his medical education at Dr. Steevens' Hospital, Dublin, where he qualified in 1865. In the following year he was appointed assistant resident medical superintendent of the District Lunatic Asylum, Downpatrick, and in 1872 resident medical superintendent of the District Lunatic Asylum, Waterford. In 1874 he became resident medical superintendent of the District Asylum, Ballinasloe, which post he held until the time of his death.

MR. JOHN KNOWSLEY THORNTON.

IT is with much regret that we announce the death of Mr. John Knowsley Thornton, of Hildersham Hall, Cambridge, on Sunday, at his residence, in his fifty-ninth year. He was educated at the University of Edinburgh, where he took the M.B. and C.M. degree in 1871. At Edinburgh he acted as house surgeon in the Royal Infirmary, and in London was consulting surgeon to the Samaritan Free Hospital for Women and Children, and to the Grosvenor and New Hospitals for Women. He was formerly President of the Medical Society of London, and was also a Fellow of the Royal Medical Society of Edinburgh, and of many other learned societies. Mr. Thornton, who held the Commission of the Peace for Cambridgeshire, was the author of various medical works. He was twice married, his first wife being Eleanor Phillipa, eldest daughter of Captain Paterson, of Castle Huntley, N.B. She died in 1886, and in 1892 he married the Hon. Mary Agnes, youngest sister of the present Lord Windsor, First Commissioner of Works, and daughter of the late Hon. R. Windsor-Clive, M.P.

SAMUEL THOMAS BADGER, M.R.C.S., L.S.A.

AFTER a long illness, Samuel Thomas Badger, M.R.C.S., L.S.A., passed away at his residence, Knowle, near Birmingham, at the ripe age of eighty-four. The deceased, who was well known and highly respected, not in medical circles alone, but by a large number of friends and acquaintances, spent nearly the whole of his life in Birmingham. The deceased leaves a widow and three sons. One of his sons is head master of King's School, Peterborough, another is practising as a surgeon, and the third, the Rev. G. E. Badger, is the vicar of Bishop Ryder's Church, in Birmingham.

SURGEON W. T. KEY.

THE death is announced of Surgeon W. T. Key, of Wyke Regis, at the age of fifty-six. He commenced practice in Wyke in 1898. An Army Medical Reserve officer and a Surgeon-Captain in the City of London Artillery for many years, he became attached to the military staff of the National Artillery Association and attended the annual camp meetings of the Association at Shoeburyness on many memorable ocasions.

DR. CHARLES EDWARD SAUNDERS.

WE regret to learn of the death at Nice of Dr. Charles Edward Saunders, who will be remembered in Sussex as the Medical Superintendent of the Haywards Heath Asylum for a period of about twelve years. Under his able administration, the East Sussex County Asylum attained a high degree of efficiency and completeness, and his genial personality will ever remain a pleasant memory to his many friends both in the medical profession and outside it. He was greatly respected among the fraternity of Freemasons. Dr. Saunders went to London, and devoted his attention chiefly to sanitary work. He was the medical officer of health for the Herts and Middlesex Combined District, and became hon. secretary of the Society of Medical Officers of Health. He was a brother of the late Dr. Sedgwick Saunders, medical officer of health for the City of London. Dr. Saunders was appointed Medical superintendent of the Haywards Heath Asylum in succession to the late Dr. Wiliams, and after twelve years' devoted service there he retired on account of failing health in 1900. The late Dr. Saunders was fifty-nine years of age. He was educated at Cheltenham,

and was M.R.C.S. England, 1864; M.B. (Honours) and C.M., 1865; M.D., Aberdeen, 1866; D.P.H. Camb., 1875 (St. Thomas's). He wrote several works and was a frequent contributor to medical journals and reports.

DR. FRIEDRICH JOLLY.

THE death of the eminent professor of psychiatry and nervous diseases in the University of Berlin, Dr. Friedrich Jolly is announced. The learned Professor was born at Heidelberg in 1844, and occupied professorial chairs at Würzburg and at Strasburg before he was called to Berlin in 1890. He was one of the leading German specialists in his own subject, and was director of the University Clinical Hospital for Mental and Nervous Diseases, as well as president of various scientific societies.

Medical News.

Royal College of Surgeons of England.

THE following is the official lecture arrangements for the first quarter of the current year at this college :—

Hunterian Lectures.—February 15th, 17th, and 19th. "The After-Effects of Head Injuries." by Professor T. Crisp English. On February 22nd, 24th, and 26th, Professor Arthur Keith will deliver a course on "The Structure and Evolution of the Auricles of the Heart, and of a competent Valvular Mechanism round their great Venous Orifices." On February 29th, March 2nd, and 4th, Professor L. B. Rawling will deliver a course on "Fractures of the Skull, including Mechanism, Pathology, Complications immediate and remote, and Treatment." On March 7th, 9th, and 11th, Professor A. W. Mayo Robson one on "The Surgery of the Pancreas."

The Arris and Gale Lectures will be delivered on March 14th by Percy J. Cammidge, Esq., M.B., on "The Physiology and Chemistry of the Pancreas." and on March 16th, by J. Herbert Parsons, Esq., F.R.C.S., on "The Neurology of Vision."

The Erasmus Wilson Lectures.—On March 21st, 23rd, and 25th, by E. M. Corner, Esq., F.R.C.S., on "Acute Infective Gangrenous Processes (Necroses) in the Alimentary Tract."

The Plumbers' Registration Bill.

ON December 29th last, a meeting of registered plumbers in London was held at the Memorial Hall for the purpose of the annual election of members of the London Registration Committee, Mr. Charles Hudson, Past-master of the Worshipful Company, being in the chair. It was stated that there are now upon the register some 12,000 or 13,000 masters and operatives and it was announced that a petition to Parliament was in course of preparation in favour of the national registration of plumbers, on lines approved by the Local Government Board, as a means of distinguishing competent workmen.

Prosecution of an Unqualified Practitioner.

JAMES CHARLES ADY, a coloured man, carrying on a medical practice at 95 Warde Avenue, Fulham, was last week summoned under the Medical Acts of 1858 and 1886 for unlawfully using the description of "Doctor," "L.R.C.P.," "L.R.C.S.Edin., 1878." It appeared that the defendant held the degrees of L.R.C.P. and L.R.C.S.Edin. in 1878. Towards the end of 1895 he brought a libel action against a newspaper, and from what transpired at the trial, the Medical Council struck his name off the Register for "infamous conduct." In January, 1898, he was convicted at the Central Criminal Court, and sentenced to seven years' penal servitude. In April, 1903, he was released on ticket-of-leave. Recently it came to the knowledge of the police that the defendant had set up as a medical practitioner at Fulham and they communicated with the Medical Defence Union. Among the evidence was the following certificate :—"I certify that Mr. Tyrell is suffering from a bad attack of influenza, and a few days' rest would greatly aid in his recovery. Signed, James C. Ady, L.R.C.P., L.R.C.S., Edin., 1878." Outside the house were two brass plates with the defendant's name and qualifications thereon, and in the window was a card bearing the words "Institute of Eclectic Medicine—Medical Superintendant, Dr. Ady, L.R.C.P., L.R.C.S.Edin., ex-Med. Reg." A penalty of £20, with ten guineas costs, or two months' imprisonment with hard labour was imposed.

Royal College of Surgeons in Ireland.

THE Annual Charter Dinner will be held at the College on Saturday, February 13th, 1904. His Excellency the Lord Lieutenant has graciously accepted the invitation of the president and council to be present. Fellows desirous of being present should send their names, and those of any guests they may wish invited to the Registrar.

Small-pox Ships for Sale.

AT a meeting of the Metropolitan Asylums Board yesterday, the Hospital Committee recommended that the small-pox hospital ships *Atlas*, *Castalia*, and the *Endymion* be sold, as they were required no longer for isolation purposes. Several members at once raised a question of the safety of selling the vessels, considering that they were saturated with the germs of small-pox, and would in all probability be a source of infection. The Chairman of the Board assured the members that the vessels had been thoroughly disinfected, and from the report of the medical officer of the Port of London on the subject there was no fear of infection. An amendment to refer the matter back for another report from the medical officer was rejected, and the recommendation adopted. One member suggested amidst loud laughter that they should be offered to the Russian Government as an addition to that country's navy.

Royal City of Dublin Hospital.

THE annual election for Resident Medical Officer will be held on January 26th. Applications to be sent on or before the 25th to Mr. G. Jameson Johnston, F.R.C.S., Hon. Sec. Medical Board.

The Late Dr. C. F. Moore.

AT the last meeting of the Council of the Dublin Sanitary Association the following resolution was unanimously adopted :—"That at this, the first meeting of the Council, since the lamented death of Dr. Charles Frederick Moore, the Council hereby give expression to the very deep regret felt by them for the loss of so highly-valued a colleague. Dr. Moore was one of the principal founders of the Association, and for many years took an active part in the transactions of its business, and recently filled the office of president. His intimate knowledge of the subject, his excellent business capacity, amiable disposition, and conciliatory manner conduced to his rendering valuable service to the cause of sanitary science. The Council deeply sympathise with his bereaved family.

International Congress of Otology.

IT is announced that the International Congress of Otology will hold its seventh congress at Bordeaux, August 1st to 4th, 1904, under the patronage of the French Minister of Public Instruction. The following subjects are proposed for discussion : 1. The choice of a simple and practical acoumetric formula, to be introduced by Professors Politzer, Gradenigo, and Delseaux; 2. The diagnosis and treatment of suppuration of the labyrinth, to be introduced by Drs. Brieger, von Stein and Dundas Grant; 3. Technique of the opening of brain abscess of aural origin, and after treatment, to be introduced by Drs. Knapp, Schmiegelow and Botey. The Lenval prize, in recognition of the greatest progress achieved in the practical treatment of affections of the auditory apparatus during the interval between two sessions of the Congress, or to the inventor of an easily portable apparatus capable of markedly improving the hearing of deaf persons, will be awarded during the Congress. The jury consists of Professor Politzer of Vienna (President), Dr. Benni of Warsaw, Dr. Gellé of Paris, Dr. Urban Pritchard of London, Professor St. John Roosa of New York, Professor Kircher of Würzburg, Professor Grazzi of Florence, and Professor E. J. Moure, of Bordeaux. The prize consists of the interest on 3,000 francs, accumulated during the interval between two sessions of the Congress. Candidates must send in a statement of their claims to Dr. E. J. Moure, President of the Organising Committee, Cours du Jardin Public, 25 bis, Bordeaux, before July 1st, 1904.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

PUBLIC HEALTH DIPLOMATE.—A valuable report upon the question of the physical improvement or degeneracy of the population, from the Anthropometric Committee of the British Association, will be found in the Proceedings of the Association, published in the year 1883. A perusal of the evidence therein contained will show that "town-life" so called is not deleterious to the race.

A CANDIDATE'S HUMOUR.

THE EXAMINER: Now sir, which is the best way to re-establish the circulation?

Candidate: That is the duty of the police, sir.

(Referred for six months.)

POST-GRADUATE.—Our correspondent is thanked for his letter. He will receive a private note in the course of a few days.

DR. I. WATSON.—The Medical and Dental Defence Union of Scotland has no connection, so far as we know, with the Medical Defence Union, Ltd., London. Apply to the Secretary of the latter.

GENERAL PRACTITIONER (Leeds).—We think that a better course would have been to have sent a friendly note drawing attention to the facts, without attributing any motive. Had this been done our correspondent would probably have received a friendly reply, together with a full explanation of the circumstances of the case.

TU QUOQUE.—There is no ethical rule upon the subject, beyond that which guides the action of one gentleman in his dealings with another.

A BARRISTER.—Your letter is unavoidably crowded out.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 13TH.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8 p.m. Council Meeting. 8.30 p.m. Mr. A. Bowlby—Pain, its Clinical Significance and Importance in Diagnosis. (Second Hunterian Lecture.)

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common).—Mr. J. H. Targett—The Causes of Uterine Hæmorrhage.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.)—5.15 p.m. Demonstration of Cases of Interest.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. J. Berry—Clinique. (Surgical.) 5.15 p.m. Dr. W. Carr—Infant Feeding.

THURSDAY, JANUARY 14TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Paper—Dr. M. de Leon (Amsterdam)—A hitherto not sufficiently recognised Source of Infection during Operations. The President—Valedictory Address. (All practitioners will be welcome.)

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY (Gt. Northern Central Hospital, Holloway Road, N.).—9 p.m. Discussion on Recent Methods of Inducing Anæsthesia (opened by Dr. J. F. Silk).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson—Clinique. (Surgical.) 5.15 p.m. Dr. P. Stewart—Myopathies.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Dr. J. E. Squire—Pulmonary Cavities—I., Signs (illustrated by cases). (Post-Graduate Course.)

FRIDAY, JANUARY 15TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Discussion on Sleeping Sickness (opened by Dr. L. Sambon).

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, W.).—5 p.m. Cases and Morbid Specimens will be shown by Dr. E. Pritchard, Mr. Brickdale, and Dr. G. Carpenter. 5.30 p.m. Papers—Dr. D. McKenzie (Leytonstone)—A Fatal Case of Streptococcus Poisoning following Measles in an Infant.—Mr. J. H. Evans—The Relation of Certain Extra and Intra-cranial Hæmorrhage in the Newborn.—Dr. G. Chaffey (Brighton)—Sequel of the Case of Extreme Wasting shown at the Provincial Meeting at Brighton.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. J. Horne—Clinique. (Throat.)

TUESDAY, JANUARY 19th.

THERAPEUTICAL SOCIETY (Apothecaries' Hall, Blackfriars.) 4 p.m. Professor Farmer will describe Some Recent Investigations on Cancer.—Papers—Dr. T. N. Kelynack—Some Points in the Hygienic Treatment of Pulmonary Tuberculosis.—Dr. Gray Duncanson—The Therapeutic Value of Suprarenal Gland Products.

Appointments.

BROWN, THOMAS, M.B., Ch.B.Vict., Resident Medical Officer to the Public Dispensary, Leeds.

CARVELL, JOHN MACLEAN M.R.C.S., L.S.A.Lond., Registrar to the Central London Throat and Ear Hospital.

DYER, SYDNEY REGINALD, M.D.Brux., M.R.C.S., L.R.C.P., L.S.A., D.P.H.Lond., Senior Medical Officer to H.M. Prison, Dartmoor.

IRWIN, S. T., M.B., Ch.B.R.U.I., Junior House Surgeon at St. Peter's Hospital for Stone, Covent Garden, London.

JONES, A. WEBB, F.R.C.S., Honorary Surgeon to the Women's Wards, Alexandria Government Hospital.

MAUNDER, PERCY R., M.D.Durh., L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer to Stafford Prison.

MUDIE, R. F., M.B., M.S.Edin., Certifying Surgeon under the Factory Act for the Ladybank District of the county of Fife.

PRICE, D., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory Act for the Works of Messrs. Boyd and Co., Castle Carey, in the county of Somerset.

SMITH, John M., M.D.Glasg., D.P.H.R.C.P.Edin., Medical Officer for No. 1 District of the Cheltenham Union.

VAUGHAN, ETHEL MAY, M.D.Lond., Assistant Physician to the Department for Diseases of Women at the Royal Free Hospital.

Vacancies.

Bethnal Green Infirmary.—Assistant Medical Officer. Salary £100 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent of the Infirmary, Cambridge Road, N.E.

Cheltenham General Hospital.—House Surgeon. Salary £80 per annum, with board and apartments. Applications to H. T. Carrington, Esq., Honorary Secretary and Treasurer.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing. Applications to the Secretary, 24 Friar Lane, Leicester.

Lincoln County Hospital.—Senior Male House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary, 2 Bank Street, Lincoln.

Liverpool Stanley Hospital.—Second House Surgeon. Salary £80 per annum, with board, residence, and washing. Applications immediately to the Chairman of the Board.

Norfolk and Norwich Hospital.—Lady Superintendent. Salary £100 per annum, with apartments, board, and laundry. Applications to the Secretary.

Rochdale Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Hon. Sec., R. W. Shaw, Esq., Southfield, Rochdale.

Stamford, Rutland, and General Infirmary.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to V. G. Stapleton, Secretary, the Infirmary, Stamford.

Tiverton, Devonshire, Infirmary and Dispensary.—House Surgeon and Dispenser. Salary £80 per annum, and all found. Applications to Arthur Fisher, Hon. Secretary.

West Ham and East London Hospital, Stratford, E.—Resident Medical Officer. Salary £120 per annum, with board, residence, &c. Applications to the Secretary.

Wolverhampton Eye Infirmary.—House Surgeon. Salary £70 per annum, with rooms, board, and washing. Applications to the Secretary.

Births.

ABERCROMBIE.—On Jan. 6th, at 23 Upper Wimpole Street, London, the wife of John Abercrombie, M.D., of a son.

HAYWARD.—On Jan. 8th, at 65 Alert Street Abingdon, the wife of M. Cecil Hayward, M.A., M.B., of a daughter.

KENNEDY.—On Jan. 6th, at Plaistow, E., the wife of Angus Kennedy, L.R.C.P., M.R.C.S., L.S.A., of a son.

WACE.—On Jan. 5th, at Walcote, Winchester, the wife of Cyril Wace, F.R.C.S., of a daughter.

Marriages.

JONES—JAY.—On Jan. 7th, at the Parish Church, Bushey, the Rev. Cyril Leslie Jones, M.A., Marske-by-the-Sea, second son of H. Leslie Jones, M.D., F.R.C.S.I., to Violet Mary, second daughter of the late James A. Buchanan Jay, of Hereford, and Mrs. Jay, Bushey.

TELLET—LITTLE.—On Jan. 6th, at St. Andrew's Church, Penrith, William Edward Tellet, M.D., Paisley, to Charlotte Edith, daughter of William Little, of Hutton Hall, Penrith, Cumberland.

WELCH—LEGG.—On Jan. 5th, at St. Peter's, Chertsey, Walter Barrows, M.R.C.S., L.S.A., elder surviving son of the late Thomas Welch, of Brighton, to Alethea Emily, only daughter of the late James W. Legg, of Ely, and Mrs. Legg, of Chertsey.

Deaths.

HEMSTED.—On Jan. 5th, at Bath, Maria Ann, widow of Henry Hemsted, F.R.C.S., of Newbury, Berks, in the 90th year of her age.

SMART.—On Jan. 7th, at Kingfield, Rye, Sussex, Elizabeth Atkinson, widow of the late Thomas William Wake Smart, M.D., of Cranborne, Dorset.

The Medical Press and Circular.

VOL. CXXVIII. WEDNESDAY, JANUARY 20, 1904. No. 3.

Clinical Lecture
ON
ENDOCARDITIS. (a)

By JOHN HILL ABRAM, M.D.Lond.,

Physician to the Royal Infirmary; Lecturer on Clinical Medicine, University of Liverpool.

IN the last few weeks two patients have died in my wards from heart disease, and the result of the post-mortem examinations has led me to bring before your notice the subject of endocarditis in general.

I wish to put on one side to-day the valvular lesions, due to the chronic process of atheroma, usually affecting the aortic valve, and associated with a similar affection of the aorta. I propose to discuss simply what I may be allowed to call true endocarditis. Endocarditis is usually classified as simple and malignant, or ulcerative, and it has long been taught that the latter variety is infective.

The broad anatomical differences between these forms may be briefly given as laid down in former years :—

	Simple.	Malignant.
Vegetations	1. Small.	Exuberant.
	2. Auricular surface of mitral v. / Ventricular surface of aortic v.	Both surfaces and on to wall of cavities and aorta, also right heart.
	3.	Ulcerations, aneurysms of valves, perforations of valves, rupture of chordæ tendinæ.
	4. No micro-organisms present.	Micro-organisms present.

In hardly any form of disease has so much work been done with regard to the relationship of organisms to the lesion, and the outcome of the work of observers, too numerous to name, has been to destroy any pathological difference between simple and malignant endocarditis.

It may be said with certainty that endocarditis, with the exception I have made, is mycotic in origin.

In the simplest type of endocarditis with the features tabulated above, organisms of various kinds have been found, morphologically identical with those found in cases with the most advanced anatomical changes. Why, then, you will ask, do the cases vary so widely in their clinical course ?

The answer, no doubt, is that in all cases two factors have to be considered, the virulence of the organism, and the resistance of the host.

In clinical work the varying virulence of the organism is difficult to gauge, but the resistance of the host is, we know, impaired by exhaustion, physical or mental, excesses of all kinds, chronic or acute disease, and in the particular form of disease we are considering by previous damage to the valves.

Some infective diseases play a preponderating part in the causation of endocarditis : acute rheumatism, scarlet fever, chorea, pneumonia, pyæmia; and less often gonorrhœa, typhoid, tubercle; and others still more rarely, as anthrax. It is rare in my experience to find the specific organism—*e.g.*, the pneumococcus ; much more commonly we find the common pyogenic cocci.

In Edith C., one of the cases before you, the fatal acute condition, though post-pneumonic, was shown during life to have been due to a secondary streptococcal infection.

In Edward H., another case before us, which followed an attack of rheumatism, streptococci have been obtained in pure culture from the valves. I have long thought, therefore, that these various affections damage nutrition, and allow in the first instance the entrance of the pyogenic cocci, and in the second place their attack upon the valves.

In this way, too, I should explain the action of Bright's disease as a cause of true endocarditis.

You will readily see, from what I have said and the hearts before you, that in the strict pathological sense no distinction can be drawn any longer between simple and infective endocarditis. Both are mycotic, and although at their extremes the anatomical differences are marked, yet numerous intermediate grades link these extremes together.

Nevertheless, when we approach the question from the clinical standpoint we must retain the old classification.

Simple endocarditis is most commonly seen with acute rheumatism. A good example of recent rheumatic endocarditis was only sent out, recovered, from X ward in October, a boy who had been left in my charge by Dr. Caton, on his retirement from the Infirmary. The important point here is the early recognition of the development of the heart trouble.

It is, in my opinion, an extremely difficult problem. Symptoms are very indefinite ; præcordial pain, palpitation, an added degree or two of temperature, an accelerated pulse-rate. These may be due to the original complaint and can have but little, if any, diagnostic weight.

A careful physical examination must be made regularly, daily, in all cases where a cardiac

(a) Clinical Lecture delivered at the Liverpool Royal Infirmary, 1903.

complication is at all likely—*e.g.*, rheumatic fever and scarlet fever. As I told you in a previous lecture on chest symptoms, a physical examination alone permits of a definite diagnosis.

What points will help us ? In the usual mitral form the first sound loses its sharp character, and becomes dull and muffled. Dr. Caton has suggested that this implies the loss or weakening of the valvular element, and the predominance of the muscular element.

Later a systolic murmur may develop at the mitral area, less often at the aortic area, and still more rarely a diastolic bruit, which more commonly is added to the systolic murmur.

The pulmonary second sound in the common mitral type becomes accentuated.

Less noteworthy is a diffusion of the apex beat.

Enlargement of the heart is rarely present in the early stage, and is suggestive rather of myocardial weakness than a secondary result of regurgitation.

The differential diagnosis has to be attempted from accidental murmurs in the strict sense, and from the murmurs of relative incompetence.

Where there is no enlargement of the heart, no accentuation of the pulmonary second sound, with a *bruit de diable* in the neck, and a systolic murmur loudest at the pulmonary area, then in the presence of marked anæmia a diagnosis of accidental or hæmic murmur is probably sound, especially when no usual cause for endocarditis is present.

Unfortunately this matter is rarely so simple.

A disease which may give rise to endocarditis may attack an anæmic patient, nay, acute rheumatism generally produces anæmia. Again in anæmia and in myocarditis relative incompetence may arise from weakness of the muscular ring, or dilatation of the ventricle, or even spasm of the papillary muscles. In these latter cases increase of the cardiac dulness will be present, and the pulmonary second sound accented.

The second sound is rarely so much accented as in endocarditis, the cardiac impulse, on the other hand, is weaker, and the pulse smaller and often irregular.

I am inclined to lay stress on the character of the first sound in endocarditis, prolongation and muffling; in relative incompetence of the mitral valve it becomes short and sharp.

The character of the murmur is of no assistance ; the time may help ; a diastolic accidental murmur is exceedingly rare. I can only add that in some cases a diagnosis cannot be made with certainty, although I think it should always be attempted. A pericardial murmur is readily differentiated, the superficial to-and-fro scratching character, the time not strictly synchronous with the heart sounds, with the further points, greatest intensity on the auriculo-ventricular line and on increased pressure with the stethoscope, make a ready recognition possible.

Pleuro-pericardial murmurs do not affect the size of the heart or alter the heart sounds, and are best heard along the edge of the cardiac dulness. Two examples of this last murmur are at present in Clarence ward.

Primary acute endocarditis usually attacks the mitral valve ; it may resolve, but very frequently leads to permanent damage. Death is never the direct result of the endocarditis.

Severe endocarditis I have never seen except in association with chronic disease of the valves, hence in the vast majority of cases the diagnosis of valvular disase is readily made.

However, in some cases which have been recorded, the local heart changes have been a post-mortem finding. In the case of Edward H., the temperature for the last ten days of his life was normal, the hæmaturia and albuminuria were thought to be due to the salicylates he had received for his rheumatism. However, the appearance of cutaneous hæmorrhages and abundant leucocytes in the urine made the diagnosis only too obvious ; he died suddenly before a blood examination could be made. (Aortic regurgitation.) In both malignant and septic endocarditis we meet fresh symptoms—marked fever of varying type, multiple embolisms, hæmorrhages into the skin and retina, enlarged spleen, hæmorrhagic nephritis.

Litten describes a form of endocarditis practically identical with the usual septic type as regards symptoms, but with three pointsof difference—it is due to rheumatism, it runs a course of weeks and months, and the infarcts never suppurate.

Dr. Glynn taught me years ago that a chronic form of ulcerative endocarditis occurred, and I have seen several cases in my practice.

Edith C., one of the cases before you, ran a course of over two months ; now this was due to streptococcus infection, yet no infarcts suppurated, and there was no history of rheumatism.

Hence, while accepting Litten's statement as to a malignant endocarditis due to rheumatism, we must remember that similar cases occur where rheumatism cannot be traced and in which ordinary organisms are found.

Finally, we have ordinary types of severe endocarditis, which are given in your text-books—typhoid and septic. Others can be manufactured, where, for instance, the heart symptoms are prominent, "cardiac type"; nervous symptoms prominent, "cerebral type." The gain thereby is infinitesimal.

You will see, gentlemen, that I practically work on—

Simple endocarditis		
Malignant	acute	typhoid
		pyæmic
	chronic	

It may be that as time goes on we shall be able to find during life the infective agent at work in individual cases, and research may then provide us with the necessary antidote.

It is an important quest, for all forms of malignant endocarditis tend towards a fatal termination : Of Litten's 20 cases, 19 died ; and the twentieth was in a bad way at the date of his paper. This is the common experience.

NOTES ON A CASE OF ENTERIC FEVER, WITH SYMPTOMS CLOSELY RESEMBLING THOSE OF PERFORATION.—RECOVERY WITHOUT PERFORATION.

By R. TRAVERS SMITH, M.D.Univ.Dub., F.R.C.P.I.,

Visiting Physician to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin.

R. D., æt. 56, a compositor by occupation, was admitted to the Hardwicke Fever Hospital on March 7th, 1903. He complained of having been ill for two weeks, during the latter of which he was confined to bed. He had not seen a doctor before admission, but had treated himself by consuming

large quantities of whisky, in the remedial value of which he had a confirmed belief. On examination he proved to be an unequivocal case of enteric fever of considerable severity. I shall refrain from detailing his symptoms, as they were the ordinary ones of enteric fever in the third week, except to say that the blood gave an unusually pronounced Widal's reaction. Dr. Earl, who examined the blood, stated that in performing this test with a dilution of 1 in 50, the typhoid bacilli were markedly agglutinated by the time he had focused the preparation under the microscope. Despite the patient's occupation, no signs of lead poisoning were present, nor had he ever suffered any of its symptoms.

Till the sixth day after admission to hospital, or approximately the end of the third week of his fever, R. D. remained in much the same condition. On that day, at 9.30 a.m., he complained of pain in the right iliac fossa and hypogastrium, after which the bowels moved, and vomiting occurred. On seeing the patient less than an hour later I found that his temperature had risen from 102° (its average on previous mornings) to 104°; the pulse was 84; the respirations 28. The abdomen had become rigid, was not distended, and not tender unless sufficient force was used to overcome the rigidity of its wall in the right iliac fossa. Liver dulness was present; elsewhere the abdominal resonance was not uniform. The general aspect of the patient was somewhat altered for the worse. He still complained of the pain. Having ascertained these points, the diagnosis of perforation was carefully considered. In the light, however, of a pulse-rate little if any above its average morning frequency, and in the absence of any indications of collapse, *despite* the onset of pain, rigidity and tenderness in the right iliac region, I was unable to form a sufficiently positive opinion to warrant the recommendation of an operation, so determined to watch the case a little longer. All food was prohibited except sips of water, but no morphia was given. An hour later the abdomen presented the same signs exactly; the pain was not so severe. The pulse had increased by four beats (to 88), the temperature had fallen one degree (to 103°). Two hours later still, all pain had gone, the pulse was 82. At 6.30 p.m. (seven hours after the onset of pain), the patient expressed himself and looked much better. He had sweated profusely, the bowels had just moved, the motion being free from blood. The pulse had fallen to 78, and the temperature had been recorded 100·6° a short time previously. The abdomen was less rigid, otherwise the same as in the morning. Accordingly progress was deemed satisfactory, more particularly as no morphia had been given to mask the symptoms of spreading peritonitis, for which careful watch was being kept.

An hour later (7.30 p.m.) the scene changed. R. D. was suddenly seized with violent pain in the right iliac region. He vomited some bilious fluid. On reaching hospital I found the patient in great distress from pain. His aspect was one of suffering; indeed, it was evident from a glance that a marked change for the worse had set in—in fact, that he was in a condition of collapse. His temperature had fallen to 96°, his pulse had become decidedly fast and reached its maximum of 140 in the course of two hours. He lay on his back with his knees drawn up. On examining the abdomen it was found not to be distended, but extremely rigid. Tenderness was more marked in the right iliac fossa than it had been in the morning, considerable pressure being required to overcome the rigid muscles. Liver dulness was present over a smaller area than had been observed in the morning, the probable result of the presence of distended intestines beneath a rigid abdominal wall. The breathing was rapid and almost entirely thoracic. The diagnosis of perforation was now irresistible. I therefore recommended immediate operation to the patient, who, though quite clear in his mind, refused. It was urged upon him that it was the only chance of saving his life, to which he replied that he would rather die than undergo an operation. The lapse of half an hour and the continuance of his pain during the time did not shake his determination. Under these circumstances I ordered a quarter grain of morphia hypodermically, and the continued abstinence from all food except sips of water, feeling at the time that the case was hopeless. The night was passed in comparative freedom from pain and with a considerable amount of sleep.

At 4 a.m., temp. 104·8°, resp. 36, pulse 96.
At 5.30 a.m., temp. 103·8°, resp. 24, pulse 100.
At 8 a.m., temp. 101·8°, resp. 28, pulse 112.

These observations go to show the fluctuations of temperature and pulse-rate which may occur in such cases, and it was noticed that as the former tended to fall the latter tended to rise in frequency, and *vice versâ*. On seeing the patient on my morning visit following, though the temperature was no longer at a point indicative of collapse and the pulse was slower, he seemed worse in other respects than on my visit the night before. His tongue and mouth were dry, voice extremely weak, muscles tremulous, prostration marked. His general appearance looked most unfavourable. The abdominal physical signs were as they had been twelve hours before; the pain, however, was less acute. No urine had been passed for at least twelve hours, yet the suprapubic region was resonant. This retention persisted for twelve hours longer without causing distress or signs of bladder distension, at the end of which time urine was passed naturally; unfortunately the quantity passed was not measured. During the next three or four days the patient lay in a truly critical state. Vomiting occurred several times daily, increasing his exhaustion. Pain became severe from time to time. The abdomen did not become distended or generally tender. The pulse, prone to fluctuation, on the average remained about 90, very weak and small. Pyrexia continued much as before the onset of the abdominal complication.

R. D. now began to improve steadily, though pyrexia continued for nearly a fortnight. As the rigidity and tenderness of the abdomen disappeared a persistent ill-defined swelling in the right iliac fossa could readily be detected. This tumefaction (almost certainly the result of local peritoneal thickening and matting) was still evident, though less distinctly so, when the patient left the Hardwicke Hospital on April 29th. No peritoneal abscess had formed. A few weeks after his discharge the patient was in his usual health.

A few words concerning the treatment of the case. Morphia was of necessity given to relieve bad pain, opium stupes gave relief when pain was less intense. The choice of diet, of course, caused the greatest anxiety and difficulty. For twenty-six hours after the onset of pain nothing was given per

mouth, except sips of water. Then dilute peptonised milk was given, two teaspoonfuls every hour at first, and gradually increased. Next a little raw meat juice and panopeptone were allowed. Even this meagre amount of food was not all retained by the stomach. Nutrient enemata were tried, but appeared to irritate the rectum and produce iliac pain; in fact, the patient developed such a terror of them that they were stopped after a few had been given. For three days after the urgent abdominal symptoms the bowels, previously regular, remained confined. A small enema of castor oil was given and produced a satisfactory fluid motion. From that time the bowels moved spontaneously every day, the movement being preceded and accompanied by abdominal pain as a rule. The origin of this pain was most probably some dragging upon adhesions.

Conclusions.—Though the existence of a perforation in this case cannot be asserted positively, it is my own opinion that such did occur. The following solution of the clinical phenomena appeals most to me. In the first instance a mild and limited peritonitis developed from inflammatory extension through the wall of the bowel, hence the preliminary pain without much constitutional disturbance. The subsequent onset suddenly of violent pain accompanied by well-marked collapse, as indicated by subnormal temperature, rapid pulse, cold sweating, &c., coincided with the occurrence of perforation. Further, peritonitis now developed, but did not become generalised owing to the existence of the following favourable conditions at the time of perforation :—

1. The bowels were comparatively empty, no food having been given for ten hours previously, and two motions having passed from them in that time.

2. Some adhesive peritonitis was already present which retarded the escape of intestinal contents, and limited the range of movement of the perforated portion of the intestine.

3. The subsequently continued abstinence from food and the administration of morphia also played their part in limiting the movement of the intestine.

Finally, I would say that if the above case was really one of perforation, it is interesting as exemplifying what is known to happen rarely, namely, spontaneous recovery after this complication. If it were not a case of perforation, it is none the less interesting as being illustrative of the impossibility of making certain of a correct diagnosis when all the classical early symptoms of perforation can be so closely imitated by some other condition.

The lesson which certainly should *not* be learnt from the case is, that it is justifiable to postpone operation when one has sufficient grounds for thinking that a perforation is probably present.

I am indebted to my late resident pupil, Miss Ovenden, for many careful observations and notes upon this case.

CERTAIN POINTS IN THE DIAGNOSIS OF FLUID IN THE CHEST. (*a*)

By T. GILBART SMITH, M.A., M.D., F.R.C.P.,
Physician to the London Hospital.

IN spite of the fact that pleurisy was so commonly met with, nothing, perhaps, was easier than to fail to diagnose it when present, or *vice versâ*. Our mistakes in this respect were often far more interesting than our correct diagnoses! The information derived from text-books about pleurisy would lead one to suppose that it was a very distinct affection, but at the bedside many of the characteristic signs were often found wanting. For instance, in a case of pleurisy with effusion we should expect to find immobility of the ribs on the affected side, and on palpation, vocal fremitus would be absent. But definite signs are very often wanting. One of the most important clinical tests was the sensation conveyed to the hands of expansion of the chest wall, a slight difference in movement being readily appreciated in this manner. Obliteration of the intercostal spaces and bulging of the ribs were, comparatively speaking, seldom seen nowadays, as the cases generally came under observation earlier. It was very difficult to obtain vocal fremitus in women owing to the lack of resonance in their voice, so that as an aid to diagnosis it was not always a trustworthy guide. The ordinary method of placing the whole palmar surface of the hand flat upon the chest was open to several objections, and he considered that the ulnar surface of the hand was better for detecting vocal fremitus, and for limiting the areas over which it could be felt.

The real difficulty lay in the fact that one was apt to mistake fluid for solid lung, and *vice versâ*. Here, again, the presence or absence of vocal fremitus was not sufficient alone, as in conditions where there was a blockage of the bronchial tubes, vocal fremitus might be absent, even when there was no fluid. The presence of tubular breathing over an effusion might lead to the erroneous supposition that solid lung was present. In purulent effusions the breathing was apt to assume a tubular character, as was also the case when the lung was compressed by a quantity of fluid, simple or purulent, or a portion of it congested. This was the class of cases most likely to mislead.

The physical signs of fluid in children were especially deceptive. An absence of breath sounds was generally held to indicate the presence of fluid, while definite tubular breathing was by no means universally present in cases of pneumonia. Another condition which was prone to mask the physical signs was that of emphysema, as in such cases the results on percussion would be very misleading. Absent voice-sounds and vocal fremitus should especially suggest the presence of fluid. The position of the heart's apex should also be borne in mind, particularly in effusions upon the left side, as any displacement of this was a most valuable sign. The number of cases in which one found trouble at the bases of the lungs was very great. Most mistakes were made, perhaps, when there was old mischief at the base associated with an effusion. Difficulty was also experienced when fluid was found together with pneumonia, especially when the former was only slight in amount.

The question as to the nature of the fluid present often presented great difficulty. Rigors were not always associated with purulent effusions, nor was the temperature invariably raised. In fact, there might be considerable pyrexia with a simple effusion. One sign was really of value, namely, clubbing of the fingers; but even here,

(*a*) Abstract of Opening Clinical Lecture of the Spring Session of the North-East London Post-Graduate College, delivered at the Tottenham Hospital, on Thursday, January 14th.

care was needed in ascertaining the exact duration of this symptom and its relation to any existing phthisical condition. His experience was that pus exaggerated the voice-sounds. Whispered pectoriloquoy was generally supposed to be lost over a purulent effusion. Another condition in which there were several small localised collections of pus forming, as it were, "pus-tight" compartments was very difficult to diagnose.

He considered that sufficient use was not made of the exploring needle in diagnosis. It was important to insert this boldly and in the right place. The best spot, he believed, was at the lower extremity of a line, one and a half inches long, drawn vertically downwards from a point midway between the two spots marking the position of the angle of the scapula when the arm was down by the side, and when it was extended above the head. This site was sufficiently far out to avoid the lung and high enough up to escape the diaphragm, while, at the same time, it was sufficiently low to permit of the easy escape of fluid, and also to allow of subsequent drainage, should this be found necessary. In advanced phthisis the removal of pus was seldom indicated, except to relieve urgent dyspnœa. Much better success had attended the operative treatment of empyemata by resection of a portion of the rib, this being a far more satisfactory method of dealing with the affection than the mere insertion of a tube between the ribs. Flat metal tubes of silver, such as those devised by Turner, were often, however, of great advantage. The use of ether during all such operations was almost always contra-indicated.

ON THE USE OF SOME OF THE NEWER ANÆSTHETIC AGENTS. (*a*)

By T. PERCY C. KIRKPATRICK, M.D.,
Anæsthetist to the Dental Hospital of Ireland.

In the study of the history and literature of the subject of surgical anæsthesia one cannot help being struck with the fact that many of the great advances which have been made in the art of the administration of these drugs have occurred in connection with their use in dental surgery. It was a dental surgeon, Mr. Horace Wells, of Hartford, Conn., who first used nitrous oxide for surgical purposes in the year 1844; it was in connection with dental surgery that the administration of nitrous oxide and oxygen was perfected, which process first enabled anæsthetists to recognise clearly the anæsthetic effects of nitrous oxide as distinguished from those of asphyxia, and, again, the necessities of dental surgery have taught us the use of that valuable sequence, nitrous oxide gas and ether. When we consider these facts it will not surprise us to find that at the present time the chief activity in anæsthetic research and experimentation is in connection with the administration of anæsthetics for dental purposes.

In spite of the title of my paper, few, if any, of the drugs which I am about to consider can be looked on as new—it is rather their combination and the method of their use which merit that description. The time at my disposal will not permit of my dealing fully with all these drugs and the combinations of them, so, while merely mentioning some of them, I shall give a more detailed account of those in the use of which I have had the most experience.

Anæsthol.—Of this drug I have no experience; it is said to be a chemical combination of ethyl chloride, chloroform and ether in the following proportions: Ethyl chloride, 17 per cent.; chloroform, 35·89 per cent.; ether, 47·10 per cent. Dr. George Foy, in a recent number of THE MEDICAL PRESS AND CIRCULAR, (*a*) speaks of it as follows: "Meyer, who introduced the drug, and has extensively used it, recommends that it be administered by an Esmarch's mask, which is covered with a doubly folded piece of sterilised gauze and a piece or oiled silk, the latter having an opening of the size of half a crown in the centre. The drug should be given as chloroform, drop by drop. The patient quickly recovers from its effects; indeed, he has never been deeply narcotised, for his reflexes have not been abolished." This drug appears to somewhat resemble in composition what is known as Schleich's No. 1 mixture, and consists of 2 parts of ethyl chloride, 4 parts of chloroform, and 12 parts of sulphuric ether. F. von Winckle (*b*) has contrasted its effects in one hundred cases with those of pure ether anæsthesia. Vomiting occurred in 67 per cent. of the cases as contrasted with 57·7 per cent. in ether cases, and in ten cases untoward symptoms occurred which made it necessary to have recourse to other means of anæsthesia.

Narcotile.—Dr. T. Eastman, of Bournemouth, has published a paper (*c*) on the use of this drug, which he states to be a pure and definite ether obtained by the direct reaction of hydrochloric acid on mixed ethylic and methylic alcohols distilled together, the vapours being condensed under pressure and purified. It is a pure and constant chemical product, and is not subject to decomposition when exposed to light. Dr. Eastman administered the drug by means of a Lobjois' inhaler in a number of cases with, as he says, very satisfactory results; he does not, however, give us any figures as to the time it takes to induce anæsthesia, or of the time available for operation after induction. He states, however, that the anæsthesia can be prolonged at will by means of a mouth or nasal tube, and quotes the case of a woman, æt. 27, who inhaled 20 c.c. for the extraction of eighteen teeth. There were no reflexes, and the anæsthesia was prolonged for eight minutes by means of the metal tube. The patient came round three minutes after withdrawing the anæsthetic, was not sick, felt nothing, and walked home half an hour after the operation. In his early cases he had several failures, but after discovering the defect he has not had a single case where anæsthesia was not extremely satisfactory. I have used the drug myself in several cases, but with indifferent results. In several cases I failed to get any anæsthesia; in others the anæsthesia was only moderately good, but in one case the result was excellent. This was the case of a girl, æt. 14, who was operated on for tooth extraction, in whom anæsthesia was induced in forty-five seconds, and who gave an available operative anæsthesia of two minutes, and made a good recovery without sickness. This leads me to think that my want of success in the other cases may have been due to my own want of experience in the use of the drug rather than any fault in the drug itself. The regulation of the air valve in the inhaler requires some experience, and I hope at some future date to make a further trial of it. The chief advantage in the drug would appear to be that it is possible to prolong the anæsthesia by means of the mouth tube during the operation, but against this we must remember that unpleasant after-effects are much more frequent after prolonged administrations.

Bromide of Ethyl (C_2H_5Br) is a drug which, though it has been very extensively used, and of which the literature is voluminous, I have no practical experience. With Continental anæsthetists it appears to occupy very much the same position as nitrous oxide gas does in

(*a*) A Paper read before the Irish Branch of the British Dental Association, November, 1903.

(*a*) THE MEDICAL PRESS AND CIRCULAR, October 28th, 1903, page 475. Since this paper was read, Dr. Meyer, writing to THE MEDICAL PRESS AND CIRCULAR, December 23rd, 1903, p. 707 states that he has used the drug almost exclusively in operations requiring general anæsthesia since October, '898.

(*b*) *Munch. med. Woch.*, January 6th, 1903. Cf. *Brit. Med. Journ.*, October 10th, 1903. Epitome, page 54.

(*c*) *Brit. Med. Journ.*, April 18th, 1903.

this country. It is used very largely for dental operations, and as a preliminary to ether. In Professor Kocher's clinic at Berne it is almost constantly used for the latter purpose, and with, I am told, excellent results. In this connection, Professor Kocher, writing to Dr. William Huggard (*a*) under the date of May 13th, 1903, says: "Nearly always I give bromethyl first and ether afterwards. I am very satisfied with the rapid anæsthesia I get from it; I have never had any death, nor even disagreeable symptoms. We give from 15 to 30 grammes at the time (for one dose). Only with *very* weak and anæmic people I prefer giving ether from the beginning." Dr. A. Brown Kelly, (*b*) in the *British Medical Journal*, states that after an administration of from fifty to eighty seconds one can, as a rule, reckon on one to two minutes insensibility in patients under four years of age, and somewhat less in those older. With respect to after-sickness, the statistics of different observers differ very considerably, as much as from 1 in 400 to 66 per cent. Muscular relaxation is often not complete, and a gag must be inserted before the administration in cases of mouth operation. A considerable number of deaths have been recorded from the use of this drug, but it is stated that, if a pure drug is used and proper precautions taken, in short administrations it is practically safe. The drug is peculiarly liable to undergo decomposition when exposed to light or air. Mr. J. P. Gilmour, in the *Pharmaceutical Journal*, (*c*) says: "During the past three years I have examined fifty specimens of bromide of ethyl (bromethane) for Dr. A. B. Kelly, with the following results: Thirty samples (60 per cent.) were utterly unfit for anæsthetic purposes owing to the presence of impurities, due either to contamination during the process of manufacture, or to decomposition by reason of age, presence of moisture, or exposure to light." Dr. Kelly, however, states that now Messrs. Duncan and Flockhart are able to supply an absolutely pure preparation. As I stated before, I have had no personal experience of the use of this drug, but am inclined to think that in view of the facts I have mentioned it is not likely to replace the use of nitrous oxide in this country.

Chloride of Ethyl (C_2H_5Cl) is a colourless mobile liquid which boils at a temperature of 12·5° C. The late Sir Benjamin Richardson (*d*) in 1867 experimented on a rabbit and a pigeon with it, but its use, until quite recently, must have been very restricted. Rottenstein, (*e*) in his work on anæsthetics, merely refers to it as a local anæsthetic; Hankel, (*f*) in his handbook on inhalation anæsthesia, does not refer to it at all; and Dastre (*g*) refers to it in the following terms: "The ether chlorhydrique, or the chloride of ethyl, C_2H_5Cl, has been tried several times by Flourens, Tracy, Babri, Harless and Heyfelder. It boils at 11° C.; at 15° C. it is a colourless gas. It is without interest." Buxton, Underwood and Probyn-Williams, in the latest edition of their text-books, where they refer to it at all, do so as a local anæsthetic only. Hewitt (*h*) devotes a page only in his book to it, quoting mainly from the papers of McCardie. I mention these facts to show you how recent is the introduction of this drug into the general practice of anæsthetists. Though this is so, we have no reason to complain of its neglect at the present time, for during the last two years quite a number of papers have been published dealing with its properties and uses. Foremost among English writers we must place McCardie, of Birmingham.

Owing to its extreme volatility, the drug is very rapidly absorbed and eliminated from the system, and this rapidity of elimination is a factor of considerable importance in its safety as a general anæsthetic. In deep narcosis the pulse appears to become somewhat slower than normal, but remains quite regular. The respiratory movements are increased in both frequency and depth, and the colour improved as a result of this and of an accompanying vasodilatation. Authorities differ as to the effects on the heart, but the weight of evidence appears to show that there is not, at all events, any marked circulatory depression. According to Seitz (*a*) the death-rate is 1 in 16,000 administrations, as contrasted with 1 in 8,000 cases of ethyl bromide; he places it as the safest anæsthetic next to nitrous oxide. Since its reintroduction, very many forms of apparatus have been devised for its administration, but an ordinary Ormsby inhaler is perhaps as suitable as any. Luke's inhaler is perhaps the most simple, consisting as it does of an ordinary face-piece with bag and angle-mount attached, similar to that of the Clover, with the exception that the angle-mount is pierced by a hole to enable one to introduce the drug into the bag while the mask is in position, the hole being afterwards stopped by a boxwood plug. Whatever apparatus is used, total exclusion of air during the administration should be aimed at, for there is sufficient oxygen in the air in the bag and the lungs to prevent cyanosis before anæsthesia is obtained. Concerning the use of chloride of ethyl in dental cases, McCardie (*b*) gives the following figures:—Single dose from 3 to 8 c.c., Ormsby's inhaler, seventy-seven cases. Average duration of induction, 50·9 seconds; average duration of anæsthesia, 71·3 seconds. Longest case of induction, 2½ minutes; longest case of anæsthesia, 2½ minutes. Shortest case of induction, 20 seconds; shortest case of anæsthesia, 3 seconds.

Vomiting is stated to occur more frequently than after nitrous oxide, but it is not persistent, and headache is frequent. McCardie sums up the position as follows: "In regard to ethyl chloride in dental work it is not to be preferred to nitrous oxide for routine use. It is of advantage in cases where the prolonged methods of administration are not available. By giving a full dose of the drug one can always be sure of one and a half minutes' anæsthesia. By reason of the portability of the apparatus and the quickness of the phases of narcosis, ethyl chloride, when administered from an Ormsby inhaler, is an ideal anæsthetic for short operations in country practice." In the case of children the drug is likely to be of very great value; all observers appear to agree that they are particularly suitable subjects for its administration. The chief drawback at present to its use is the after-sickness, and it is on this point that we require further information, which can only be derived from patient and close observation of a number of cases. It may be that such observation will lead to the discovery of the cause of this phenomenon and the means of avoiding it, and if it does so, I believe that chloride of ethyl will in the future take a very high place among our general anæsthetics.

Quite recently Hewitt has introduced a method of giving chloride of ethyl and nitrous oxide gas mixed, which promises to give very good results. I think the best way that I can describe this method to you is to quote the words of Dr. Hewitt, in which he described it at the annual meeting of the British Dental Association last June. Hewitt (*c*) says:—"In order that this method may be thoroughly understood, it is necessary to recapitulate certain facts concerning nitrous oxide, to which I drew attention many years ago. If a full two-gallon bag of the pure gas be taken, if an accurately-fitting face-piece and efficient valves be used, if two or three expirations be allowed to escape through these valves, and if the valves be then thrown out of action and the remaining quantity of nitrous oxide be breathed backwards and forwards, anæsthesia with a minor degree of asphyxia will ensue with a rapidity varying with the type of subject. Thus, while this particular method of anæsthetising by nitrous oxide would in the case of a tall, powerfully

built man take about a minute and a half to produce anæsthesia, and whilst the anæsthesia would be unattended by noticeable asphyxial symptoms, the same method would, in the case of an anæmic young woman of short stature, induce anæsthesia in about forty-five seconds, and the anæsthesia would be accompanied by obstructive stertor, epileptiform spasm, or both of these conditions. Now, supposing we wish to produce a similar anæsthetic effect in each case, and supposing that our procedure, so far as the escape of two or three expirations is concerned, remains the same, we shall find that our object may be readily attained by regulating the quantity of nitrous oxide originally present in the bag, a full bag being required for tall, plethoric or alcoholic subjects, and two-thirds, one-half, or even one-third of a bag being advisable as we descend the physical scale to the feebly nourished and anæmic child."

These are the considerations which underlie the method we are about to discuss, which aims at producing a partial anæsthesia with a limited quantity of nitrous oxide, eliminating all asphyxial symptoms, and then so adding ethyl chloride that the partial anæsthesia is replaced by the deep anæsthesia of the latter drug. In order to effect this the following procedure is adopted. An ordinary two-gallon gas-bag is filled about three-quarters full for the average patient, and then detached from the gas bottles; a small glass tube charged with from 3 to 5 c.c. of chloride of ethyl is now fixed by a piece of rubber tubing to the stop-cock at the bottom of the gas-bag. The face-piece is accurately adjusted to the patient, who is then permitted to inspire gas and expire through the valves for two or three breaths. The valves are then thrown out of action and the patient permitted to rebreathe the gas. In about twenty seconds the stop-cock is opened and the chloride or ethyl introduced into the bag. The patient now breathes the vapour of chloride of ethyl mixed with nitrous oxide till anæsthesia is complete. The time which it takes to induce full anæsthesia varies, but it is stated to be much shorter than that which would be necessary to induce a similar state of anæsthesia by either agent separately. Hewitt has given us no record of actual times, so I am not able to contrast it wih the figures I have already given you for somnoform and chloride of ethyl. In nineteen administrations some days ago I got myself the following figures:—

Average time of administration, 66·7 seconds; average time of anæsthesia, 66·3 seconds.

Ten of these case were boys of the average age of 13·1 years. This is not at all as good as McCardie's results with chloride of ethyl, but it must be remembered that they were my first cases, and my first experience of the method, and I have no doubt very little practice would greatly improve my results. The type of anæsthesia was in every case excellent; there was no cyanosis or jactitation, and rarely any phonation,—a remarkable fact in view of the number of young boys in the series of cases. The absence of cyanosis and jactitation, with their accompanying swelling, turgescence and rigidity of the parts about the mouth, are points of considerable importance to the operator, who is thus given every facility for his manipulations with the mouth. None of my patients appeared to experience the slightest difficulty in taking the anæsthetic, and in no case was there any struggling during the administration, though I must admit there were none of the so-called bad subjects in the series. As a rule the recovery was excellent, though not, I think, as sudden as after simple nitrous oxide anæsthesia; all the patients were, however, able to walk into the recovery room within two or three minutes of the termination of the operation. Three patients vomited some little time after recovery, but this vomiting was not attended with any distressing symptoms of sickness or prostration. On the whole, the recovery was, I should say, almost as good as that from ordinary nitrous oxide anæsthesia. At present we are not able to speak with any degree of confidence as to the question of the safety of the method, but this much I can say, that in none of my cases did I see any symptom which gave rise to the least alarm, and Hewitt has had the same experience with his cases. The method has the advantage of being easy to carry out, the apparatus simple and inexpensive, and the drug not costly. The signs of anæsthesia which I found most trustworthy were a slightly snoring respiration, fixity of the eyeballs, marked diminution if not complete loss of the conjunctival and corneal reflexes, and general flaccidity of the voluntary muscles.

I do not know of any previous record of the combination of these drugs, but ethyl bichloride, or ethidene dichloride, as it was called, was used by both Clover (*a*) and McLeod (*b*) as far back as 1880. Clover records quite a number of cases in which he used it for both major and minor operations.

I have endeavoured to give you a brief description of the use of some of the newer methods of inducing anæsthesia for dental purposes, relying chiefly on my own experience where that was available, and supplementing it by that of others where my own was deficient. I have confined my remarks to those methods which for their own use do not necessarily demand the assistance of a skilled anæsthetist in addition to the operator, as I considered that these methods would be of more interest to the majority of my hearers. I firmly believe, as indeed my position would enforce me to, that the best results in operations under anæsthetics can only be attained when the operator can give his undivided attention to the operation, and the care of the anæsthesia is entrusted to a skilled anæsthetist, but I also quite recognise that the exigencies of practice often render this desirable ideal unattainable. In a very large majority of dental operations I believe that the nasal method of administering nitrous oxide gives us the very best results for both patient and operator, whether the operation be long or short, but this method necessitates the assistance of an anæsthetist, and one, too, who has had considerable practice in its use, if good results are to be attained, and consequently I have not touched on it in this paper.

Death Under Ether.

AT Shelley on the 13th inst., an inquest was conducted by the Coroner on the body of a single woman, of Town End, Shelley, near Huddersfield. The evidence showed that the woman had undergone an operation six months ago for tumour of the breast. She consented to another operation, and in both instances ether was administered. There were no signs of fainting at the first operation, and on Monday it took about ten minutes to get her under the influence of the ether, which was administered by Dr. Smith, of Middlestown, while the operation was performed by Dr. Nesfield, of Shelley. The latter stated that his attention was drawn to the woman's condition as he was about to stitch the wound up. Artificial respiration was resorted to, but without avail. The cause of death was sudden failure of the heart's action, which, in his opinion, was due to the ether. The jury returned a verdict of "Misadventure."

French Congress of Climatotherapy and Hygiene of Towns.

THE first Congress will be held at Nice, during the Easter vacation, from April 4th to 9th. Professor Chantemesse has been named President; the Vice-Presidents are, Professor Renaut, Lyon; Professor Grasset, Montpellier; Professor Calmette, Lille; Dr. Balestre, Nice. The discussions will bear on five questions:—(1) the climate of the French Mediterranean coast; (2) adaptation of the individual to climate; (3) influence of the French Mediterranean coast climate on tuberculosis and tuberculous patients; (*a*) clinical and critical discussion on the special conditions required in order to benefit by this influence; (*b*) treatment of such patients at their homes; (*c*) treatment of such patients under supervision, sanatoria for patients in easy circumstances; establishments for

the treatment of poor patients suffering from scrofula or pulmonary tuberculosis; (4) the influence of climate on the French Mediterranean coast on rheumatism, and on those subject to rheumatism; (5) disinfection of towns. Great travelling facilities in France and abroad will be granted to members of the Congress and their families. The hotel prices at Nice will be reduced in their favour and may be ascertained beforehand. Full particulars will be furnished on application to Dr. Hérard de Bessé, Secretary-General of the Congress, Beaulieu-sur-Mer. The members of the executive committee for England are: Dr. G. H. Brandt, Nice; Dr. Johnston Lavis, Beaulieu; Dr. MacDougall, Cannes; Dr. Price Mitchell, Monte Carlo; Dr. Stanley Rendall, Mentone.

The Out-Patient Departments

LEICESTER INFIRMARY.

Case of Pulmonary Osteo-Arthropathy.

By ROBERT SEVESTRE, M.D.,
Assistant Physician, Leicester Infirmary.

THE patient, Joseph C., æt. 19, at work in the shoe trade, presented himself in the Out-patient Department, and was admitted into the Leicester Infirmary in May, 1903. When a child of seven he had the measles, which was complicated by a severe attack of bronchitis; since then he has had a cough, which in the summer gives him no trouble, but in the winter is always severe. Four years ago he states that he had pleurisy on the left side of his chest, and about the same time he expectorated some blood. At different times since then there has been hæmoptysis, but not in any large quantity. During the last two years the character of the cough has changed, coming on in paroxysms, especially after meals, and accompanied with the expectoration of a thin, green fluid of an unpleasant smell—at times amounting to half a cupful. In the autumn of 1901 he dislocated the left patella; the joint became swollen, and never resumed its natural size. In August, 1902, he noticed a little stiffness and swelling about the right knee-joint, and in the following October he was laid up in bed for about one week with what he calls an attack of rheumatism. His limbs ached and he felt feverish, and the wrist-joints and some of the phalangeal joints of the fingers became stiff and swollen, but there was very little pain. During the next few months his general condition improved, but the condition of the affected joints and the cough, with its expectoration, did not materially alter. His past history had been uneventful, and he denies lues. Other members of the family are healthy.

When admitted into the Infirmary he presented the appearance of a tall, spare youth, having a pale but healthy colour. The tongue was clean. The wrist-joints and the first phalangeal joints of the fingers were swollen and stiff, so that the hand could not be tightly closed. Both knee-joints contained fluid, the left more than the right. There was no pain, and the skin over the affected joints presented nothing unusual.

The ends of the fingers and toes were clubbed and a little congested in appearance, and he says he does not remember the time when his fingers were different from the thickened and rounded condition in which they are at present. Cough comes on in paroxysms, usually in the morning and after meals, with expectoration of a faint mortar-like smell, greenish-yellow in colour, not very tenacious, and devoid of air; in quantity about three ounces a day. On examining the sputum no tubercle bacilli were found.

On inspection of the thorax it was seen that the left side was contracted and flattened, with diminished movement on respiration, and that the spine showed a lateral curve to the right in the lower dorsal region. The vocal vibrations on the right side were felt normally; on the left they were diminished in the upper part of the chest, and in the lower part of the lateral region and at the base were barely perceptible. The percussion note was hyperresonant on the right side, much diminished on the left, and below the level of the angle of the scapula it was dull. The breath sounds on the right side were exaggerated with a few *râles* at the base; on the left side in the upper part they were diminished and moist *râles* were added; over the dull area they were feeble, and just below the angle of the left scapula bronchial in character. The physical signs, however, on the left side of the chest varied from time to time, the variation being dependent, probably, upon the amount of secretion present in the bronchial tubes. For instance, at one examination along the lower part of the inner border of the left scapula, cavernous breathing with consonating *râles* and pectoriloquy were audible. The apex beat of the heart was situated in the sixth left interspace in the anterior axillary line. The sounds of the heart at the apex were regular and clear; in the pulmonary area a faint, rough ending was heard to first sound, which was most marked on expiration. The pulse-rate was seventy-eight, regular and of good volume. Nothing abnormal was found on examining the abdomen. The urine contained no albumin or sugar. The patient was placed on a full diet with cod-liver oil and malt. He was allowed to be in the grounds of the Infirmary as much as possible.

After the first week of his stay in the Infirmary he had creosote vapour baths given every other day, the quantity of the vapour and the duration of his stay in it being gradually increased. Under this treatment he improved considerably; the temperature, which was slightly raised on admission, fell very soon to normal; the swelling and stiffness gradually disappeared from the wrists and fingers, and the fluid from the knee-joints almost disappeared, a little remaining in the left; the expectoration lost its offensive character, but the quantity did not diminish to any great extent, remaining about 1½ oz. daily. The gain in weight was 3 lb. The physical signs in the chest, however, did not materially alter. Since his discharge in July, 1903, his condition has remained much the same. The expectoration, he says, amounts to about 2 oz. daily, and he gets it up in about five minutes when it bothers him most; at times it is slightly offensive, and is occasionally streaked with blood. The joints have given him no further trouble.

Remarks.—The physical condition of the lungs calls for no special comment; the signs indicated that there was a condition of bronchiectasis in the lower lobe of the left lung. It is difficult to say what part the creosote vapour baths played in the amelioration of the patient's symptoms. During the inhalation of the vapour the

greater portion of the daily quantity of the expectoration was brought up; the quantity itself was not materially altered, but the unpleasant smell disappeared. It seems probable that this alteration in character bore some relation to the great improvement that took place in the affected joints. The improvement in his appetite may have been partly due to the effect of the creosote, and partly to the fact that he was out-of-doors the greater part of the day. Whether this class of case, in which joints become affected in disease of the chest, disease which is always chronic and usually suppurative, merits a description as a distinct clinical entity is very much to be doubted. It seems more probable that the condition of the joints is a complication dependent on some infective condition within the chest; that it is an infective arthritis comparable to that met with in other morbid states.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXIX.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

STOURFIELD PARK SANATORIUM, POKESDOWN, BOURNEMOUTH.

STOURFIELD PARK has had a somewhat varied history. The estate is an old one, but the present handsome building was apparently the work of speculative builders, and affords evidence that it was originally designed to serve as an attractive and convenient residential hotel. Before completion as such, it appears to have undergone a metamorphosis, and emerged as a sanatorium. In 1899 the establishment was under the control of Dr. Denton Johns, who left, however, in consequence of differences with the lay conductors. He was succeeded by Dr. David Thomson. The institution is now, we understand, in some way amalgamated with Hailey Sanatorium, near Wallingford. Dr. Frank Fowler is the senior resident physician, and is assisted by Mr. H. M. Bullock, as junior resident physician and bacteriologist, while Dr. Charles Reinhardt is the visiting physician, and is "responsible, jointly with Dr. Fowler, for the general control of the Stourfield Park Sanatorium."

The sanatorium is situated at Pokesdown, some three miles from either Central Bournemouth or Christchurch. It is on a slight eminence overlooking the valley of the Stour, and is some 600 yards from the sea. The site is of sand and flint gravel.

There are about ten acres of ground studded with pines, cedars, beech, chestnut and oak. The lawns are particularly attractive and the shrubberies and paths have been conveniently arranged.

Unfortunately, however, the establishment is being rapidly surrounded by new buildings, and the adjacent pine-studded country is now succumbing to the destructive inroads of the irresistible builder.

The building, which is of modern appearance and rich in attractiveness, is in many ways well adapted to its present purpose, although far removed from the desirable simplicity so strongly advocated by Dr. Reinhardt, and to a great measure exemplified at Hailey.

The building faces south by south-west. The ventilation and sanitation and general construction have been wisely arranged. The rooms are of good size, lofty, and are provided with much window space. There are open fireplaces. In not a few cases the bedrooms open on to a verandah or balcony.

The corridors are fine and stylishly decorated and quite hotel-like. They are well ventilated and are warmed by hot-water pipes.

There are three storeys, the ground-floor with administrative quarters, reception and dining-rooms, the upper floors reserved for patients, while the attics are used by servants. There is an electric lift.

Ventilation is assisted by electric fan extractors. There is a good supply of baths. The sanitary requirements appear to be excellent. The whole establishment is lit by electricity. Heating is provided for both by open grates and hot-water pipes.

The sanatorium possesses its own laundry, disinfector, and electro-therapeutical equipment.

Accommodation is provided for forty-five patients. We had the privilege of dining with the patients and observing something of the general routine of management.

Treatment is conducted on the now generally established hygienic lines. Dr. Frank Fowler, who has himself undergone treatment at Hailey, resides in the sanatorium with his wife and exercises a constant personal supervision.

In the grounds are seventeen admirably designed and attractive-looking kiosks or châlets, each simply furnished with couch and table, and fitted with electric light. Here the patients are supposed to spend their time when not at meals or taking exercise. These shelters are well placed and so constructed as to allow of exposure to air and sunlight, and yet secure protection from winds.

The fees are from four to five guineas a week, according to accommodation, and are inclusive of medical attendance and ordinary nursing. There are a few rooms at three guineas. Patients whose condition renders it necessary to have their meals served in their rooms are charged one guinea a week extra, and cases requiring a special nurse must pay her fees and board. Alcohol is only allowed when especially prescribed, and must be paid for by the patient.

The sanatorium is within three miles of either Bournemouth Central or Christchurch stations, at each of which cabs meet all trains. Boscombe and Pokesdown stations are rather nearer, but fast trains do not usually stop at these.

The telegrahic address is "Sanatorium, Pokesdown," and the telephone 445 Bournemouth.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

(SECTION OF OBSTETRICS.)

DR. A. J. SMITH, President, in the Chair.

THE Section met in the Royal College of Physicians on January 8th, 1904.

Dr. PUREFOY read the report of the Rotunda Hospital for the year 1902-03.

Sir ARTHUR MACAN proposed, and Dr. W. J. SMYLY seconded, that the discussion of the report be postponed until the next meeting of the Section. The resolution was unanimously carried.

The following specimens were also shown:—

Dr. PUREFOY.—Fibroid uterus removed by supravaginal amputation.

Dr. TWEEDY.—(1) Diseased tubes with enlarged ovary, removed by bisection of uterus and vaginal hysterectomy. (2) Cystic implantation tumour removed from abdominal scar, the result of a former ovariotomy.

THERAPEUTICAL SOCIETY.

MEETING HELD DECEMBER 22ND, 1903.

DR. DIXON described the action of drugs upon the pulmonary vessels. The experiments were undertaken conjointly with Professor Brodie, and consisted in the artificial perfusion of the lungs outside the body. He first showed that these vessels have no nerve supply, and hence drugs which produce vaso-constriction on ordinary systemic vessels have no effect on those of the lungs. The action of drugs on these vesssels was divided into three groups. Group 1, represented by pilocarpine, adrenalin, physostigmine and digitalis, all of which act on peripheral nerve endings and therefore, whilst producing marked constriction of systemic vessels, have no action on the pulmonary. Group 2, drugs acting directly on muscle, such as barium, calcium, veratrin, &c. These produce constriction of all

vessels throughout the body, including those of the lungs. Group 3, drugs producing vaso-dilatation. These were represented by nitrites and caffeine. Both produce very decided vaso-dilatation of systemic and lung vessels, and must therefore act directly on muscle. In conclusion, Dr. Dixon described how injection of such substances as digitalis or adrenalin gave rise to marked pulmonary congestion.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD JANUARY 7, 1904.

RUSHTON PARKER, ESQ., B.S., F.R.C.S., President in the Chair.

DR. A. S. GRUNBAUM showed an experiment to demonstrate the hæmolytic action of radium rays on red blood corpuscles.

Dr. STENHOUSE WILLIAMS exhibited and described a new ethyl chloride inhaler. Given by his method the patient was under in 50 seconds, the anæsthesia being maintained with ether. He had found it very useful in alcoholic subjects.

Dr. F. W. BAILEY had noticed that patients frequently came out of the ethyl chloride anæsthesia before ether anæsthesia was induced.

Sir William Banks and the President also spoke.

Mr. R. C. DUN read notes of a case of congenital hydronephrosis, due to stricture of the ureter at its junction with the renal pelvis. The chief point of interest lay in the fact that the abdominal tumour was principally on the left side, and was not palpable in the right loin. The diagnosis of left hydronephrosis was made. On peforming nephrectomy through an incision on the left side, a normal left kidney and ureter were exposed. The tumour, which proved to be a hydronephrosis of the right kidney, lay in front of the left kidney, and was readily removed. Recovery was uneventful. A congenital displacement of the right kidney, either to the middle line or into the loin of the opposite side, probably explained the abnormal position of the hydronephrosis.

Dr. Blair Bell and the President commented upon the case.

Dr. C. THURSTON HOLLAND read a note on the X-ray diagnosis of kidney stones; he laid special stress on the necessity in making a negative diagnosis of taking the X-ray whilst the breath was held. Also the importance of obtaining a plate showing differentiation of the shadows of the soft structures lying between the iliac crest and the lower ribs. The note was illustrated by a series of lantern slides showing stones *in situ*, and also the type of negative to be aimed at.

Drs. W. Carter, Chas. Macalister, and Alexander spoke, and Dr. Holland replied.

Dr. C. BROWN exhibited an old note-book containing notes on Dr. John Rutherford's clinical medical lectures delivered in Edinburgh in 1749, and read a paper on the subject. After giving an account of Edinburgh, the medical school, and Dr. Rutherford, he referred to the total absence of anything like scientific observation in medicine, but pointed out that the rate of mortality in Dr. Rutherford's wards was, under the existing circumstances, not at all a discreditable one. Dr. Cassels Brown gave details of the treatment adopted in cases of anæmia, rheumatism, ague, phthisis, syphilis, cardiac disease, and hydrophobia, and in conclusion remarked that while the medical profession had advanced scientifically to an enormous extent, it had not advanced equally in other directions. He suggested that more attention should be given to the teaching of practical therapeutics, and advocated a modified return to the culture of the old-time physician. The President, Sir William Banks, Dr. Grünbaum and Dr. Logan spoke, and Dr. Cassels Brown replied.

CLAMS AND TYPHOID.—An outbreak of typhoid fever has occurred in the district of the Strood Rural District Council, Rochester, through the patients having eaten clams. The Council has issued notices warning persons against using this kind of shell-fish.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 16th, 1904.

TREATMENT OF CANCER BY ADRENALIN.

DR. A. RODIN, who has been making a special study of adrenalin in its effects on cancer, reports that, in cancer of the rectum, from thirty to sixty drops in a tablespoonful of water, of the solution of 1—1,000, applied daily to the parts, removed the oozing from the anus and diminished for a time the volume of the cancerous granulations. The external cancerous ulcers became pale under its effect, diminished in volume, and the progress of the affection was retarded.

Combined with quinine and beer-yeast, adrenalin seemed to prevent relapses after ablation.

A woman was operated on at Lyons for cancer of the uterus, total ablation, in 1901. The operation was incomplete, and a rapid return of the disease was expected. The patient was submitted to the following treatment: During five days she was given five grains of quinine twice a day; the five following days she took a teaspoonful of beer-yeast each morning, when she returned to the quinine for another five days, and so on during a month. After this period she was ordered to suspend the treatment five days, after which to recommence. A year afterwards adrenalin was added to the treatment, five to ten drops of the 1—1,000 solution was given morning and evening. The patient continues to be in excellent health.

Another patient operated on three times in the interval of a few weeks for cancer of the breast, which returned each time immediately, was treated in a similar manner, and no relapse took place.

THE HYPODERMIC TREATMENT OF SYPHILIS.

As mercurial injections in the treatment of syphilis constitute a convenient and very effective treatment of the specific disease, it may be well to indicate the different points of election for the insertion of the needle according to different authors.

1. The point preferred by Barthelémy is situated on the middle of a line running from the antero-superior iliac spine to the upper extremity of the fissure of the nates, corresponding to the external border of the gluteus maximus.

2. The "point of Galliol," two fingers' breadth above the great trochanter, at the intersection of a horizontal line drawn at this point and a perpendicular line running parallel, but at a distance of two inches, to the groove of the nates.

3. The "point of Smirnoff," a finger's breadth behind the upper part of the great trochanter.

4. The "point of Fournier," corresponding to the upper third of the buttock.

The needle should never be planted into the middle of the gluteal region, which constitutes a dangerous zone on account of possible wounding of the nerves or vessels, nor in the inferior portion, on which the patient sits.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 16th, 1904.

AT the Society for innere Medizin, Hr. Litten showed the preparations and related the following case of

TWO DIFFERENT KINDS OF MALIGNANT TUMOUR IN THE SAME PERSON.

A woman, æt. 73, suffered from melano-sarcoma of the choroid that had developed so that it could be seen, for the eye could not be illuminated on account of a complete opacity of the cornea. Besides this primary

melano-sarcoma of the retina, with exudation so that the membrane was raised up, it was attached only at the optic papilla, and there was carcinoma of the gall-bladder that could be felt on the liver as a hard nodule the size of a walnut. As a rule, metastases of melano-sarcoma were met with as bulky tumours in the liver. At the autopsy the gall-bladder was found distended and containing a large calculus, by which the viscus was divided into two parts. The stenosis was caused by an adeno-sarcoma.

The speaker had also seen a second case of melano-sarcoma of the choroid without metastases in a case of pernicious anæmia. In 1888, he had demonstrated to the Society a case he had had under observation for four and a half years. In 1884 enucleation had been performed, but advised long before. A few weeks later an enormous tumour of the liver and spleen was found. The man had had the melanosis for five years. There were fluctuating spots from which, by puncture, dark-coloured contents were evacuated. There was also melanuria. According to Hirschberg's statements, patients with melano-sarcoma of the choroid who remained free four to five years after enucleation were to be looked upon as cured. But Paul Guttmann had shown a patient in 1879 with retro-bulbar sarcoma that had driven the bulb well forwards. Operation was deferred, and later on the tumour shrank so that the exophthalmos disappeared. Thirty years after metastatic tumours appeared, from which the man died. Another case was recorded in which metastases recurred after ten years. It was not safe, therefore, to prophesy.

Hr. Westenhoeffer reported a case of

SPONTANEOUS RUPTURE OF A CARCINOMATOUS LIVER.

The liver weighed 3,000 grammes, and had numerous spontaneous ruptures on the surface, through which the carcinomatous masses projected.

Hr. Strauss remarked of the case that it was one of original carcinoma of the stomach, and that the disease had developed in the liver secondarily. During the final days of the patient's life, there was rapid loss of strength with black vomit, so that death was attributed to internal hæmorrhage. Bleeding had never been seen, however, when the stomach was washed out. The reason was that the motility of the stomach was retained perfectly, so that the blood was never detained, but expelled immediately.

At the Dermatological Society, Hr. P. Strassmann related a case, previously shown, of

MULTIPLE NEUROTIC GANGRENES OF THE SKIN.

Small circumscribed gangrenous patches had appeared on the vulva, which had been authoritatively declared to be tuberculous or para-tuberculous. A histological examination had not negatived this view. Total extirpation had in consequence been performed on the patient. The appearance of recurrences gave rise to an opinion that they were multiple neurotic necroses. The patient was therefore carefully watched, and proof obtained that the skin necroses were caused by the application of zinc chloride by the patient herself. At the same time, slight stricture of the rectum was diagnosed, the cause of which could not be determined. The patient left the hospital and entered the Urban Hospital, where the medical officers, knowing nothing of her previous history, performed laparotomy. Extirpation of the rectum was carried out at the same time. In the discussion it was mentioned that the patient made the confession in consequence of a suggestion, in the belief that her case would thereby be rendered more interesting. They had not been able to produce similar necroses by chloride of zinc. In other ways the patient was tuberculous. The speaker observed that an explanation of the patient's behaviour was made clearer by the assumption of sadistic sensations.

The *D. Zeitsch. f. Chir.* has a paper (Festschrift für Esmarch) on the question of

OPERATIONS FOR TUBERCLE OF THE PERITONEUM.

Soon after the surprise given by König nearly twenty years ago, when he declared that tuberculous peritonitis, up to then considered to be a fatal disease, was amenable to simple laparotomy, experiences began to pour in as numerous as mushrooms after rain. Those who read them had to conclude that in abdominal section we had an infallible cure for tuberculous peritonitis. Only cases that recovered were published. Afterwards, however, when material from large institutions came to hand, it was seen that deaths still took place, but much less frequently than formerly. Then some rejected operation as dangerous. Internal treatment also showed good results. The author propounds the question whether we should treat the disease by operation, and holds that we should in cases of the chronic exudative form, operation not being too early resorted to, and in cases in which a primary lesion exists in the tubes which can be treated at the laparotomy. Whether operation should be performed in all cases is doubtful, and a decision can only be reached through further observations. The counter-current has brought some good with it in that it is opposed to indiscriminate operation. The writer has shown elsewhere that tuberculous peritonitis is a disease that has a tendency to recovery, that this tendency can be supported in suitable cases and at a suitable stage in its course by laparotomy, and this is a view that is gradually making way.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 9th, 1904.

APPENDICITIS.

UNDER this title Zahradnicky gave an historical account of several operations for appendicitis, necrosis, &c., or, in other words, a year's practical work in which appendicitis largely bulked.

In thirteen cases operated on, seven were of a chronic recurring nature, all of which recovered rapidly after the operation. The symptoms were mostly confined to the disturbances in the alimentary tract, due to adhesion, &c.

The other six were operated on immediately the diagnosis was made. In two of the cases there were intraperitoneal abscesses; one of these died from sepsis.

In his criticism of injury to the abdomen he considers early interference necessary to save life; even though the injury be a very simple one no time should be lost in performing laparotomy. This late action in slight cases is deeply to be regretted by most surgeons, and is the most fruitful cause of the greatest number of the cases operated on, while the most serious are more successful owing to early operation.

Zahradnicky is a zealous devotee of medullary anæsthesia and loudly praises the many advantages obtained from this form of narcosis, which, he maintains, are far superior to the usual practice of general narcosis. He recorded 300 cases on which he had operated with this form of anæsthesia. One of these cases deserves special notice. A girl, æt. 13, suffered from hip disease, which had to be resected to remove the osteomyelitic material, and for this reason a combination of the general and medullary anæsthesia was practised. Within twenty-eight hours after the operation the patient

died. The result of the post-mortem attributed death to the use of the chloroform.

Jaroslav Hausman said he preferred Bier's anæsthesia in operation on the vulva, vagina, perineum and inguinal regions. He has applied it in eighty of his operations and only met with one case that gave any sign of collapse. This was a case of pronounced obesity with arterio-sclerosis, for which the uterus was enucleated.

TABES DORSALIS.

Rohác reported three cases of tabes dorsalis which recovered by indifferent treatment. One of the cases was in the paralytic stage of the disease and was considered hopeless according to Romberg's experience. The usual course had been gone through before this fatal form of the disease had set in without any apparent effect on the progress of the morbid phenomena. The case was finally put aside as incurable, but to the surprise of all recovered, and walks about quite well!

The next case he gave the history of was first seen in 1891, when total paraplegia was stated to be present with paralysis of the bladder. He came to hospital for treatment. Though the case was considered hopeless he was allowed to remain with probably a placebo. After fourteen days the patient began to improve, and in six weeks he went home on his own feet without even a crutch. No return of the trouble has been observed since. The third case had a similar history.

CALCAREOUS VESSELS.

Pelnár next gave the Society a long history of an alcoholic patient, æt. 67, who was described as of a healthy family. He complained for years of headache, vertigo, pain in the feet, burning in the soles, general weakness, dulness of vision, and sluggish perception or, in short, a state of meiopragia.

The objective symptoms were an extensive calcification of the vascular system, accentuation of the second cardiac sounds, no hypertrophy of the heart, increased vascular pressure, and albumin in the urine. The pulse was quite imperceptible along many of the arteries, but in spite of this no obliteration or endarteritis could be perceived, as the process was so diffuse without trophic disturbance. It seemed to assume a form of atheroma without involving the aorta or the splanchnic region.

Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, January 16th, 1904.

AT a recent meeting of the Budapest Royal Society of Physicians and Surgeons Dr. Dollinger, Professor of Surgery in the University, read an interesting paper on the

OPERATIVE RELIEF OF THE LUNG COMPRESSED BY PSEUDO-MEMBRANES DUE TO CHRONIC PYO-PNEUMOTHORAX,

of which I give the following abstracts:—In the incipient stages of this disease surgeons have usually followed the Estlander-Letievant method, and removed portions of ribs corresponding to the area of the pyo-pneumothorax, while in cases of greater severity, if necessary, all the ribs and the parietal layer of the pleura were removed. The soft parts of the thorax were pressed close to the lung and adhered to it; while the lung proper remained in its compressed state. In 1894 Delorm first attempted to get rid of the pseudo-membrane enveloping the lung and binding it down. This attempt was followed by success, so that in 1896, at the Congress of French Surgeons, he was enabled to bring forward twenty cases of the kind, partly his own, and partly those of others who had followed his method. Among these cases seven proved successful. The patient whom Dollinger showed suffered from adhesions in the region of the fourth intercostal space, 5 cm. outwards from the sternum in the left half of the thorax. This happened in December, 1899, and although this soon subsided, the patient had another attack in January, 1900, followed by pleuritis, the purulent exudation breaking through the intercostal space. It was in this state that he sought advice at the Klinik in April, 1900, when he had already a pyo-pneumothorax, which filled the greater part of the left half of the chest, and which communicated, through the above-mentioned fistula with the surface. Dr. Dollinger performed the Delorm operation. Through one incision he cut away the third and fourth ribs, this incision commencing just outside the sternum, on a level with the second intercostal space; thence he passed outwards for about 10 cm., bringing the incision perpendicularly as far as the second intercostal space, and passed parallel to this as far as the sternum. This incision went through all the soft parts, through the pectoralis muscle and the intercostal space, in front of the axillary line corresponding to the perpendicular line he had made across the ribs. In this way he made a movable flap comprising the fourth and fifth ribs. This door was strengthened by the sternum side, and could be opened after having broken through the cartilages of the ribs. One could then see clearly into the chest. After removing the pus, it was evident that the lung was compressed towards the middle line, so that it only reached to the edge of the sternum; the lung, moreover, was bound down by a 1 cm. thick pseudo-membrane, which Dollinger readily removed. The lung then expanded in the open chest, and entirely filled it down and backwards. Suppuration continued about five weeks, but during the first days of this period the fistula healed, and at present over all places of the pneumothorax one can hear respiration. Dulness is present only over the lowest part of the chest, where thick pseudo-membranes still exist. The same operation was performed by Dollinger on another patient, æt. 45, who had suffered for five years from pyo-pneumothorax. This patient had been operated upon by three surgeons without result. In this case the removal of the pseudo-membranes was not quite as successful, and therefore the lung could not expand so completely; consequently, the suppuration did not cease after the operation. In such a patient the best course, perhaps, would be to perform, either immediately or later, the Schede operation.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

EXCISION OF THE UPPER PART OF THE RECTUM (KRASKE'S METHOD).—RESTORATION OF CANAL.—Mr. CARLESS operated on a woman, æt. 41, who had suffered from occasional hæmorrhage from the rectum for some months, and from a mucous discharge for about six months. She had experienced a good deal of pain lately, and the hæmorrhage had been more marked. There was no pain on action of the bowel, but a good deal of opening medicine was required. The face was pallid and anæmic, and she had recently lost weight. On examination, a growth with everted edges could be detected two or three inches from the anus; it was nearly annular, but a small portion of the mucous membrane on the posterior aspect was free. The growth was hard but freely movable, and there was no evidence of secondary infiltration of glands or of secondary deposit in the liver; it was therefore a favourable

case for Kraske's operation. The patient was placed on the table face downwards, and with the pelvis somewhat raised. An incision was made from just below the top of the coccyx in the middle line upwards as far as the base of the sacrum. The soft parts were stripped back from the bone mainly on the left side. The coccyx was then removed, as also the left lateral margin of the sacrum, the incision in the bone skirting the third left sacral foramen. The tissues were then opened up and the rectum exposed. With a little difficulty the finger was passed round the bowel below the peritoneal reflection. By a little dissecting the growth was now isolated, a procedure which necessitated the opening of the peritoneal cavity through Douglas's pouch. No viscus escaped, but a strip of sterilised gauze was introduced to protect the cavity and prevent any protrusion. It was then easy to still further free the growth, as also the glands in the meso-rectum, which were enlarged. The meso-rectal tissues were now nipped through with scissors, and bleeding points secured by ligature. Sterilised tapes were tied round the bowel above and below to act as clamps, and the diseased portion of bowel was removed. After the bleeding had been stopped, it was found that the portions of bowel above and below could be approximated, but before effecting this the peritoneal cavity was closed. An incision was made over the anterior aspect of the rectum allowing an edge of the peritoneum to be turned up, and this was carefully stitched to the anterior margin of Douglas's pouch. Thus the peritoneal cavity was closed off. This transverse cut in the peritoneum was made about an inch and a half above the section of the bowel. Approximation of the anal and upper portions of the tube was now effected by means of a Murphy's button, but a good deal of over-stitching was required in order to make good the lower segment, the muscular wall of which had been torn in freeing it at an earlier stage of the operation. No attempt was made to close the wound in the soft tissue, which was packed with gauze and the patient sent back to bed. Mr. Carless pointed out that he had not undertaken a preliminary colotomy in this case as he had every hope of restoring the continuity of the canal. In his opinion colotomy was valuable in cases that could not be dealt with by excision or as a preliminary to excision where the anal segment of the bowel had to be removed, as under these circumstances the anus that resulted was almost certain to be either contracted or so patulous that the patient had no control. He had, he said, made every effort to save the nerves going to the sphincter by limiting the part of the sacrum that was removed, and he hoped that at any rate a partial union of the segments united by the Murphy's button would result, as thereby a much better issue would be attained. The after-history of this case has been interesting. The union of the two segments was not perfect, the bowel giving way in three spots, and for some time the whole of the patient's fæces passed through the wound. The button was set free about the sixth day, and was removed through the anus. The openings in the line of union have gradually closed, and about six weeks after the operation the patient began to pass her fæces *per anum*, the sensation of which is normal, and the sphincteric control of which is perfect. At the present time (about eight weeks since operation) the wound is contracting rapidly, the communication with the bowel is almost closed, and the patient's motions pass almost entirely by their natural passage. In all probability the complete continuity of the canal may be expected when the sacral wound is sealed.

The growth is a columnar-celled carcinoma, but the pathologist reported that the enlarged glands in the meso-rectum were merely inflammatory.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

OPERATION FOR STRANGULATED INGUINAL HERNIA IN AN INFANT, ÆT. THREE WEEKS.—Mr. KELLOCK operated on a male child, æt. 3 weeks, the subject of a strangulated right inguinal hernia. Even for its age it was an undersized, wasted child. The history was that soon after birth a hernia had been discovered in the right inguinal region, which, up to the day previous to operation had been reducible. On that day all efforts to reduce it had been unsuccessful and the child had been in some pain and had been sick. He had been fed only by the breast. On examination, a tense, rounded swelling was found occupying the usual situation of right inguinal hernia. It reached downwards a short distance into the scrotum; the testicle could not be felt below it, but it was thought that the organ could be distinguished in the lower end of the hernia; the child was also the subject of a rather tight phimosis. After the parts had been cleansed as far as possible, an oblique incision was made over the swelling and deepened until the sac of the hernia was reached; the latter was rather dark in colour and very tense. On opening it was found to contain no fluid, but a coil of small bowel was found lying immediately in contact with its inner surface. The opening in the sac was enlarged upwards, and the bowel drawn out and examined; it was discovered to be a piece of small intestine about two inches in length in a fairly satisfactory condition, but showing well-marked signs of constriction, both above and below. With a little difficulty it was found possible to return the bowel to the abdomen without making any incision at the constriction; it was then apparent that the testicle was contained in the sac of the hernia, which was therefore divided transversely about an inch below the external abdominal ring, the upper part dissected up, ligatured by transfixion and removed. A small portion of the lower part was also removed and the testicle returned to the scrotum. One silk stitch having been passed through Poupart's ligament and the edge of the conjoint tendon approximating the walls of the inguinal canal, the wound was closed by a continuous horsehair suture and a dressing of collodion and gauze applied. Mr. Kellock remarked on the early age of the little patient for such an operation; he said that strangulated inguinal hernia was not very rare in infants, and probably only differed from the same condition in later life in the greater difficulties of the operative treatment. The difficulty of getting the region perfectly clean in the first place is great. The hernia is, as in this case, very often marked by a total absence of fluid in the sac, rendering the greatest of care necessary in opening it. In this case, he said, the returning of the bowel to the abdomen, so often a matter of considerable difficulty, was comparatively easy. He also pointed out the fact that the hernia was of the congenital variety, rendering it necessary to divide the sac of the hernia transversely before removing any portion of it. He thought the dressing which had been applied—namely, collodion and gauze above without wool or bandages, was the best calculated to keep the wound clean because owing to the size of the child it would be practically impossible to keep a larger dressing from becoming soiled. He also pointed out that, considering the operation had not been a long one, and the condition easily remedied, the prognosis was entirely favourable.

DR. H. W. BEACH, of Putney, has been elected Medical Officer of Health for Yarmouth. He was one of five selected candidates.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 20, 1904.

THE BRITISH MEDICAL ASSOCIATION AND THE GENERAL MEDICAL COUNCIL.

WE have carefully watched the columns of the official organ of the British Medical Association during the past few months for some explanation of the reasons which led that body to formulate a demand for direct representation on the General Medical Council, but up to the present little information has been given. It appears that a resolution was passed last July begging that in any future legislation affecting the constitution of the General Medical Council, direct representation in proportion to its members should be given to the British Medical Association. We confess we can see little justification for such a proposal, and we do not believe for a moment that it will be seriously considered by Parliament. It is true that the great majority of medical men in these islands are members of the British Medical Association, which is therefore, in the widest sense, representative, and has on many occasions voiced the opinions of the profession with dignity and force. But we do not see that the individual practitioner who is a member of that Association has any just claim to greater representation in the General Medical Council than the individual practitioner who is not a member. At present a member of the profession has his interests represented in two ways. He has first, the direct representative or representatives for whom he votes, and he is, in addition, represented, though indirectly, by the nominee of university or corporation from which he holds his diploma. Why should the individual practitioner be entitled to get further representation by merely joining the British Medical Association? Whatever steps may be necessary to secure a greater direct representation of the profession—and we have always urged reform in this direction—we do not think the object aimed at will be gained by endowing the members of the British Medical Association with a representation refused to others. Again, if the claims at present made be at all admitted, the difficulty at once rises as to where to draw the line. If one voluntary society be entitled to direct representation, why not another? The British Medical Association is the most powerful medical corporation in England, but the Irish Medical Association occupies a similar position in Ireland. Indeed, in one sense, it has a stronger claim to represent its members in public matters, since its primary work is in the field of medical politics, while the British Medical Association is primarily a scientific body, and only by an after-thought political. Similar arguments might be made use of on behalf of the Medical Defence Union, and, indeed, any other medical society strong enough to make its voice heard. Unique as the position of the British Medical Association may at first sight appear, we believe that it would be a very dangerous precedent to give any voluntary association of medical men power to govern those who are not members of that Association. And, indeed, we do not think that the Association would be at all wise to take on the proposed responsibility. Its work is already becoming too unwieldy for the most efficient management, and any further plan to withdraw energy from the pursuit of its scientific objects is, at the least, of questionable wisdom. The resolution we have discussed is at present under the deliberation of the divisions, and it is with satisfaction we note that such an important body as the Dublin Division has already expressed its unqualified and unanimous condemnation. It need hardly be added that the adequate representation of the whole profession on its governing body—a much-needed reform—stands on an entirely different basis from the proposal to add another class interest to those that at present constitute one of the most autocratic and irresponsible public bodies in the United Kingdom.

ALCOHOLISM AND RACIAL DETERIORATION.

THE so-called alcohol question is receiving much attention in relation to the alleged deterioration of our people. It is to be hoped that the Government inquiry now in course of initiation will procure trustworthy evidence on this matter. Considerable discussion has taken place respecting the contentions of Dr. Archdall Reid that alcohol, like disease, is the cause of an evolution protective against itself. Nature, it is true, works for the elimination of the drunkard; but the practical conclusion of Dr. Reid's argument, as stated in the current number of the *British Journal of Inebriety*, will shock the humanitarian sensibilities of many: "We have no real choice between the reformer's method and Nature's method. The reformer's method has long been out of court. Whether we help or resist, Nature will do her work. If we help, she will do it quickly and with mercy; if we resist, she will do it slowly and with infinite cruelty." Doubtless, while there is much that is repellent in such a view, there is also much that is peculiarly attractive to the superficial scientific

fatalist. Not a few, however, hold that what is ethically wrong cannot be scientifically right. And now Dr. Ford Robertson, the distinguished pathologist to the Scottish Asylums, has taken up the scientific cudgels, and at the last meeting of the Society for the Study of Inebriety, argued that the Reid school had founded their argument on an insecure and even false foundation. Dr. Robertson holds that the distinction between inborn and acquired characters is really an artificial and useless one, and if such can be substantiated, Dr. Reid's structure collapses like a pack of cards. Certainly, many careful observers will be inclined to agree with Dr. Robertson that at the present time one of the most potent causes of genetic variation depends upon the action of alcohol, and probably the majority will, whatever theoretical support they may be inclined to give to Dr. Reid's theories, agree with Dr. Robertson's practical advice that it is the duty of the State to remove from the environment of its people every inimical condition to which there is imperfect adaptation. The temperance question, thanks to the researches of many scientific investigators and the work of such bodies as the Society for the Study of Inebriety, is now no longer the battlefield for vulgar fanatics and irresponsible cranks, but one concerned with the highest interests of our people, and offering opportunities for study of the most serious and important of biological and ethical problems. The question is one which no medical man can now afford to neglect.

KÖPLIK'S SPOTS IN MEASLES.

MEASLES is a disease to which the public are apt to attach but scant importance. It is exceedingly common and widely distributed; generally mild and of low fatality. Almost everybody has had measles in childhood, and most people regard it as one of the inevitable incidents of the early years of life. To them it ranks with teething and vaccination as one of the drawbacks to the pleasure of having children. And yet measles demands an annual toll of human life as great as all the scheduled dangerous infectious diseases put together. The promoters of Public Health Acts did not urge its inclusion among the compulsorily notifiable diseases, presumably because of the hopelessness of taking any steps to limit its spread, although the mere fact of making it notifiable would have had a considerable influence in drawing attention to its being something far more serious than a mere puerile ailment. But the disease has proved so refractory to preventive measures that one large town, in which compulsory notification had been in force for some years by special order, decided the other day that the amount of good that resulted from notification was so problematical that they withdrew the obligation to notify. Now, in what does this difficulty in dealing with measles consist? There are two contributory factors. One is the extremely generalised character of the influences that tend to produce the disease in individuals, and the other is the difficulty of early diagnosis. The first of these is beyond our ken at present, but to the second we would like to direct attention. The first symptoms of measles are no more than those of a feverish cold—a little bronchial, nasal, and conjunctival catarrh accompanied by pyrexia. Unless he has particular reason to suspect measles, the practitioner hesitates to turn the house upside down and isolate every case of febrile catarrh that he is called on to attend; such a procedure causes great domestic upset, and does not tend to enhance his reputation when it turns out (as it frequently does) that his suspicions are unfounded. The usual plan is to wait till the fourth day to see if a rash appears, though if it does it generally happens that the harm has been done, and the other children in the house have been infected. The early diagnosis of measles, then, is a great *desideratum*. It seems curious in this connection that the lesions of the buccal mucous membrane known as Köplik's spots should not have received wider recognition than has been accorded to them. These spots were first definitely described by Filatow in 1895, although it is possible that Flindt may have indicated the same changes in his paper published in 1880. The subject was not taken up till 1896, when Köplik, of New York, wrote, in the "Archives of Pediatrics," an account of them, which differed somewhat from that of Filatow, but was undoubtedly intended to apply to the same lesions. At all events, Köplik's name came to be associated with the discovery, and for good or evil, Köplik's spots seem likely to take rank with other eponymous pathological phenomena in the nomenclature of the future. These spots are described by different observers as white, bluish-white, and bright red, the truth seeming to be that they are all three colours at different stages; red at first, then white with a red areola around, and finally bluish-white in the centre, white in the periphery, and surrounded by a ring of injected mucous membrane. As to their site there is no dispute. Most commonly they are found in the buccal mucous membrane opposite the molar teeth, but they may also occur in the inside of the lips and on the palate. The area they cover varies from a mere point to the size of a silver penny-piece. Now the important clinical point with regard to these spots is that they appear, as a rule, within twenty-four hours of the initial catarrhal symptoms, and thus are visible two, three, and sometimes four days before the appearance of the rash. They are peculiar to measles; they are not found in scarlet fever, rötheln, or any other disease. They are characteristic in appearance and position; they can be easily differentiated from thrush, stomatitis and adherent milk-curd. Here, then, we have a most valuable means for aiding early diagnosis. Observers who have systematically watched for these spots have seen them in 90 to 100 per cent. of the cases that subsequently proved to be measles, and this has been the case in England, America, Germany, and Austria. The latest to publish

his results, M. Marvasse, in *Die Heilkunde*, discovered them in forty-five out of forty-eight consecutive cases, and this is rather below than above the average of previous observers. We think that this clinical phenomenon cannot be too widely known, for its early recognition may save many a case from the personal infection of measles. It certainly adds a weapon of great power to the practitioner's armamentarium, a weapon that has been sadly needed in the past.

Notes on Current Topics.

Dublin Hospitals and "Poor" Patients.

OUR contemporary, the *British Medical Journal*, does not appear to have a very correct knowledge either of the position which the Dublin hospitals occupy with regard to the community at large, or of the source of their funds. A medical man, who rather thinly veils his identity under the initials "W. H. N.," writes to our contemporary to complain that he sent a child suffering from intussusception to a Dublin hospital, and that it was refused admission. He then wrote to the secretary of the hospital to complain, and getting no answer stigmatises the Dublin hospitals as frauds on the charitable public, because they are unwilling to receive poor patients who do not bring grist to their mill. To his letter our contemporary appends the note that "it is understood that the Irish hospitals object to receive pauper patients," and that "as the Dublin hospitals are almost entirely supported by the State grant, they have not much to do with the charitable public." We do not profess to know the source of our contemporary's information regarding the Dublin hospitals, but we would point out first that no Dublin hospital refuses a patient who is a fit subject for charitable relief and for hospital treatment if it has a bed vacant in which to place the sufferer. Secondly, that, as unfortunately the State grant is insignificant in proportion to the needs of the hospitals, even with the very large sums annually subscribed by the charitable public—a source without which most of the hospitals might close their doors—many patients have to be turned away for want of accommodation.

The Physiology of Shaving.

IT is curious how content we are, day after day, to use the shaving-stick without a knowledge of its method of action. We do not know for how many generations it has been the custom to aid the razor by soap, yet it would appear that the *modus operandi* of the lather was never explained. We are all empirics in our shaving, and a rational basis of our practice is for most of us yet to seek. Happily, a writer in one of our contemporaries has come to our relief, and, late as it is, has reduced the action of soap on hair to the sphere of natural law. It appears that the ordinary haphazard explanation that soap extracts oily matters, and thus renders the hair brittle, is worse than merely erroneous, for not only are the premisses false and the conclusion illicit, but even were the conclusion admitted, it would not explain the phenomenon under investigation. In fact, what happens with the hair is the very reverse of becoming brittle, for when a hair is soaked in soap solution for some time it becomes soft, and it is this softness, and not any imagined brittleness, which makes the hair easy to cut. A few simple experiments are sufficient to settle the question. If three separate hairs are taken for purposes of examination, and after soaking one in water, another in soap and water, and leaving the third untreated, are examined under a microscope, certain facts are observable. The hair which has been lying in water has become somewhat swollen, and cuts with a clean section as compared with the broken or frayed edge shown on cutting the untreated hair. Further, the soaped hair is much swollen, and cuts with great ease, showing a perfectly clean section. The fact is, then, that alkalis soften such structures as hair and epidermal thickenings, and it is only on drying that this softness gives way to brittleness.

Pig-Sticking Extraordinary.

ONE of the curiosities of surgical literature is a pig-sticking story just come to hand in an Indian contemporary. An officer, while pig-hunting, came up to a pig and succeeded in sticking it, only to have the spear immediately jerked out of his hand. As the spear fell to the ground it became free of the pig, and, in the rebound, pierced the pony's shoulder. The point entered under the near shoulder, pierced the chest wall between the tenth and eleventh ribs and protruded through the saddle. It then pierced the left buttock of the rider about the middle of the thigh, and emerged behind the great trochanter, finally coming to rest behind the shoulder. The pony luckily stopped dead still, and was held while the shaft of the spear was divided and the parts drawn out. Nine inches of blade and twenty-one inches of shaft had pierced the rider, while, in addition, three feet of torn bamboo handle had passed into the pony. The thigh wound was superficial, no important structure being injured, and healed rapidly. The pony, unfortunately, developed pneumonia and died. The case is interesting, as the writer justly remarks, not only as showing the vagaries of a spear in a very few moments, but as demonstrating that such a wound need not become septic if properly treated at the time.

The Dangers of the Bath.

HAPPY were the days before we knew anything of bacteria and their habits of life. In the good old days we read our letters at the breakfast-table—as some of us do still in spite of the warnings of one of our contemporaries—without any thought of the unseen foe which adhered lightly to the envelope that we dropped carelessly on the buttered toast. We drank our milk without any thought of suppurative mammitis to turn it to curds in the mouth. We slaked our thirst at the wayside brook without caring that a case of typhoid fever had been treated on its banks a

few hundred yards away. Nowadays we do none of these things, for we know that the bacillus is lurking everywhere to catch us unawares. We had got used to guarding against the enemy which is wont to enter our mouths with any unconsidered trifle of food or drink, and we thought that in doing so we kept sufficient watch. It seems that we were wrong, for the latest stronghold captured is, of all things, our morning tub. Surgeon-Major Beevor, in a recent paper, (*a*) discusses the whole question of typhoid infection from bath water, and shows without much difficulty the great ease with which bacteria may gain access to the mucous cavities during immersion. During the rainy season in India the water supply is, of course, specially liable to bacterial contamination, since it is impossible to protect it from inflow of surface water. Now the rainy season coincides with the enteric season, and it is likely enough that the cause of the increase of enteric fever at that period of the year is due to an excess of surface water finding its way into the supply-tanks. It is obvious that water which is open to suspicion should never be used for drinking purposes without boiling, and Surgeon-Major Beevor is right in suggesting greater caution in the bath than is commonly observed.

Alopecia and Dental Caries.

THE relationship between alopecia and dental caries is not, at first sight, particularly obvious; nevertheless when the facts of the correlation of growth are borne in mind, a possible explanation may be discovered which does not involve either reflex irritation or bacillary infection. It has been observed that certain malformations very frequently co-exist for which no cause can be assigned. Animals which present the most abnormal appearances in their teeth are likewise most abnormal in their dermal coverings. The narwhal is a good example of this peculiar association of abnormality of teeth with specialised integument, having a hairless body, thick deposit of subcutaneous fat or blubber, an enormously developed left tusk, with an undeveloped or rudimentary right tusk. The facts which led M. L. Jacquet to ascribe baldness to the presence of carious teeth, together with the general impression which exists that young people suffer more in this respect than was formerly the case, suggests that a modification of our epithelial structures may be taking place, which may best be described as an associated epidermal degeneration, manifesting itself in dental caries and alopecia. The cause of dental decay is no doubt to be found in the fact that, for some generations cooking has rendered thorough mastication less necessary, and that the teeth are consequently atrophying from disuse, and their capacity for resisting the ravages of micro-organisms correspondingly diminishing. M. Jacquet's theory calls attention to a possible remedy for baldness—*viz.*, to attend to the teeth, particularly the milk-teeth, which are too often neglected on account of their comparatively short life. The association of good teeth and hair, though frequently commented upon, has not so far raised the conjecture that their decay and deficiency may be correlated.

(*a*) *Indian Med. Gaz.*, October, 1903.

Public Night Shelters.

THE misery and hardships endured by thousands of individuals who are compelled to wander through the streets of the metropolis at night can only be adequately described by those who have actually experienced them. The cry of the homeless and shelterless is one to which many philanthropic agencies have responded, and yet their numbers seem scarcely diminished. The Salvation Army authorities early recognised their responsibilities in this direction, and the outcome of their labours is nightly appreciated by a host of destitute and outcast men and women. The suggestion recently made by Mr. G. J. Cooper, chairman of the Public Health Committee of the London County Council, that the municipality should provide night shelters on somewhat similar lines available for those who are unable to afford even a sixpence for a bed is one which should be commended for the consideration of that august body as likely to meet a real and growing need among the very poorest of the citizens of London. The regulations controlling the management of those already in existence were passed by the Council without objection, even though their hygienic conditions were not, perhaps, always of the most first-class description. But there is no reason why certain buildings, such as warehouses, could not be adapted to this beneficent purpose, or other and cheaper structures built of a more sanitary nature which would meet all the necessities of the case. Strict supervision would, of course, have to be exercised with regard to the arrangements for sleeping and for disinfecting beds and couches. The nightly visit of a sanitary inspector might be of assistance in detecting some of the more acutely infectious diseases, and any such cases could be promptly referred to a medical man. The idea of making any profit over the undertaking is, as Mr. Cooper sagely remarked, out of the question.

Apparent Improvement in Disease Symptoms.

FEW phases of disease are more mysterious to the lay mind than those periods of remission which occur from time to time during its course. At such times the patient begins to take greater liberties with himself, and the hopes of his friends are falsely raised by the transitory improvement. But after the calm comes the storm. The old symptoms return unabated, and seem to have gathered fresh strength by their temporary abeyance. Many diseases of the nervous system are characterised by these periods of remission, insomuch that the very fact has been utilised as a prognostic sign, though, in many cases, it becomes a matter of no small difficulty to gauge accurately the course of events pursued by the malady. From the point of view of treatment the question is one of great importance, as grave pathological

changes may be in progress, hidden, perhaps, from the patient, and even veiled from the perception of the physician, during the time that the intensity of the symptoms has abated. That such a condition of affairs may be met with in acute appendicitis has been recently pointed out by Sir William H. Bennett, (*a*) who has shown that a sudden fall in the temperature, together with a diminution of the pulse-rate, may occur, and the patient may express himself as much more comfortable, while the state of the appendix is, nevertheless, going steadily from bad to worse. This fallacious sign of improvement was accompanied, in the case of a boy of fifteen, by gangrenous inflammation of the appendix, which was removed by operation. The cessation of pain and the apparent amelioration of the symptoms was due, in reality, to septic intoxication from the focus of disease. Sir William Bennett also points out that a sudden drop in the temperature is not infrequently the precursor of gangrene in appendicitis, so that such a fall is often to be interpreted as a signal of danger.

Juvenile Cigarette-Smoking.

SIR WALTER RALEIGH has much to answer for, probably more than most of the characters described in his "History of the World." For did he not introduce into Europe the weed that has been the source of more theoretical discord and practical solace than any other substance except alcohol? It would hardly be too much to say that of the physiological and pathological effects of tobacco-smoking we know next to nothing, which, considering the enormous quantity of tobacco that is annually consumed in Europe—7,000,000,000 cigarettes are smoked in England alone every year—argues that it cannot be such a deadly poison after all. Nicotine is debited by the non-smoker with all the vices outside the decalogue, but the proportion of nicotine in the modern light tobaccos is almost negligible. Such effects as are produced are probably far more due to other empyreumatic substances, so complex as to mock the efforts of the analyst, but the blessed word "nicotine" still bears the brunt of the objurgatory onslaughts of tobacco-detractors. The chief disability that tobacco-smoking has been demonstrated to place its adherents under is a slight—very slight—loss of muscular power, but this is so infinitesimal that it is hardly worth considering. Intemperate smokers sometimes suffer from temporary cardiac palpitation, and more or less chronic pharyngitis with hypertrophy of the adenoid tissue of the posterior pharyngeal wall is common. Beyond these it is extremely difficult to trace any physical derangement to tobacco, except the rare tobacco-amblyopia. The worst results of smoking are undoubtedly moral, over-indulgence of the habit tending to produce contentment, inertia, and lethargy in its devotees. It is really for these reasons that juvenile smoking should be discouraged, and the British Anti-Tobacco League may do some good if they get their Bill, proposing to make it an offence to sell tobacco to boys under sixteen, through Parliament. The various organisations which have the "anti-smoking" cause at heart are becoming more and more active, the International Cigarette League having 600 branches and 21,200 members in this country alone. A badge is worn, and a member caught smoking on the sly is set upon by his comrades and deprived of his insignia. These Leagues are nothing if not militant, and so long as they confine their activities to looking after the youngsters and not making themselves ridiculous they are to be commended.

(*a*) *Lancet*, January 2nd, 1904.

Erythema Scarlatiniforme Desquamativum Recidivans.

ONE is not surprised to find that the description of an affection with this ponderous designation comes from the pen of Kramsztyk, and is to be found in the *Dermatologische Zeitschrift*. But in spite of its forbidding title the disease is one that claims very careful consideration, for though the condition is rare, its recognition would save one from an unfortunate error if one came upon it unawares. Relapsing desquamative scarlatiniform erythema, as its name implies, is an affection whose cutaneous appearance is that of a punctate erythema like that in scarlet fever, while it further apes that disease by being followed by desquamation. In fact, its diagnosis presents great difficulty, unless the patient has had former attacks. The throat and tongue lesions that are so characteristic of scarlet fever form a useful means for differentiating between the diseases, but in mild scarlet fever the fauces and tongue may be so slightly affected that too much reliance must not be placed on their aid. Even the course of the disease will not always decide the point, as otitis media and even nephritis have been noted as sequelæ of desquamative erythema. The only certain guide to a correct interpretation of the symptoms is to be found in the occurrence of previous attacks. In the three cases reported by Kramsztyk, one had had no less than nine attacks, and the other two had had two and three respectively. The conditions would seem to be a general infection of a similar nature to the other exanthemata, not merely a local skin affection as has been thought. There has been but little attention paid to desquamative erythema in this country, and probably most medical men have not met with instances of it in their practice. It is well, however, to be on one's guard, for the diagnosis of scarlet fever is puzzling enough without this added terror lying in wait to catch one tripping.

Contaminated Shell-Fish.

THE dangers of eating raw shell-fish, not only oysters, but mussels, whelks, *et hoc genus omne*, has been several times mentioned in these columns, and now comes an authoritative pronouncement on the subject. It takes the form of an interim report by the Royal Commission on Sewage Disposal, which has been sitting for some years. The report is clear and emphatic as to the possi-

bility of contaminated shell-fish being the cause of enteric fever and other illnesses in man; in support of this opinion they refer to the disastrous consequences that followed the consumption of oysters—the only article of diet that the guests ate in common—after the mayoral banquets at Winchester and Southampton in 1903. This conclusion is supported by much evidence, especially that of the medical officers of health of Brighton, Yarmouth, Southend and Manchester. The Commission is equally clear as to the remedy—"We are strongly of opinion that the only way in which this evil can be effectively dealt with is by placing tidal waters under the jurisdiction of some competent authority." The authority suggested is the Rivers Board, the local body which now administers the Rivers Pollution Prevention Act. Glad as one is to hear a good principle so emphatically stated, one cannot help regretting that the proposed new powers are not to be conferred on the local sanitary authority, for not only is disease-prevention their function, but they have a trained expert to advise them on these matters, which the Rivers Board has not. In the absence of such advice, the Rivers Board could not be expected intelligently to anticipate and deal with all the sources of danger that might arise. To medical men the remarks of the Commission on the help that may be expected from bacteriology are very significant. Hitherto the presence of *Bacillus coli communis* in shell-fish has been regarded as evidence of contamination, but Dr. Houston, at the Commissioners' bidding, examined 1,000 oysters from various beds and layings, and found that from nearly all, including those from obviously pure sources, that organism could be obtained by culture. The oysters from the more foul sources, as a rule, showed a larger number of bacilli than those from pure sources, and the Commission suggest that it may be possible in the future to establish a quantitative test, but in the meantime the significant remark is made that "results of bacteriological examination must be interpreted in the light of topographical observations."

Smoking in Reading-Rooms.

OPINIONS differ considerably with regard to the effect produced upon the mental faculties by smoking whilst engaged in reading. Many students assert that the habit is distracting, and one which impairs markedly the power of concentration. On the other hand, others believe just as strongly that it renders the perceptive faculties keener, and actually enables them to do better work. It is largely a matter of custom. If it be granted that smoking may sometimes be an undesirable accompaniment of hard study, it is quite otherwise where light reading for purposes of recreation is concerned. The subtle aroma of the fragrant weed seems then to lend enchantment to the plot and increased vividness to the scene, while the blue, curling wreaths of smoke become transformed into veritable garlands ready to weave themselves around the heads of our favourite characters. From the more material and hygienic standpoint there is much to be said in favour of the suggestion which has been made to allow smoking in our public reading-rooms. As a disinfectant, the fumes of tobacco would possibly be useful in preventing many forms of infectious complaints, and the concession, if adopted, would be one which would be appreciated by large numbers of the working-classes. The chief objection seems to be one of accommodation, for, obviously, separate news-rooms to those already provided would require to be built, and, on grounds of expense alone, the idea might have to be abandoned in certain districts. Special precautions would have to be taken and strict rules enforced with regard to spitting, but it should not be a matter of difficulty to provide fixed receptacles which might serve the double purpose of ash-tray and spittoon. An object-lesson as to the proper disposal of sputum would thus be constantly before the public.

Education by Suggestion.

MR. HAMILTON ARCHIBALD has been conducting a series of experiments on school-children with the idea of showing how much can be done in the way of teaching children by suggestion. Under the influences brought to bear large numbers of children were induced to believe (or say they believed) quinine was tasteless, eau de Cologne did not smell, and such-like absurdities. Of course, Mr. Archibald's idea was not to impress such nonsense on the young mind, but only to see how far the process could go in dealing with children. It is difficult to make out what was gained by the experiments except a demonstration of the well-known fact that the psychological attributes of a collection of individuals is not the sum of the psychological attributes of the component individuals, and of the even better known one that some children will say anything they are expected to say. It is to be sincerely hoped that such a method of instruction will find no place in our educational system. Hypnotic suggestion, or quasi-hypnotic suggestion, is likely to prove gravely deleterious to weak and unstable minds, and the object of education should be to educate, to bring forth, the powers latent in the mind, not to stuff it with suggestions good, bad, or indifferent. The only legitimate way in which suggestion may be employed is by the example of the teacher's own conduct, but to introduce even beneficial knowledge by the exercise of suggestion to enthralled children is not only deplorable in its stupidity, but positively baneful.

Voluntary Cardiac Inhibition.

THE power of directly controlling the action of the heart is a rare attainment possessed by a few individuals only. It is generally supposed that this ability is entirely dependent upon the strength of the will, the exercise of which is known to influence many of the bodily functions. Some physicians have been enabled to inhibit voluntarily their own cardiac action, but recognising that the

practice is not unattended by danger, have wisely abstained from exhibiting this strange power. The presence in this country of a certain Hindoo Mahatma, who is accredited with the power of thus directly producing complete cardiac inhibition, has naturally aroused considerable sensation in the public Press. The practice, however, is assiduously cultivated by many of the Indian jugglers and "holy men." Any power by which man is enabled to exert a mysterious influence over himself or others at once renders that individual an object of reverence to the superstitious Easterns, who believe him to be in touch with the supernatural. The effect upon the heart produced in this way is, in all probability, due to increased inhibition through the vagi. It is well known that tumours, or other morbid conditions affecting these nerves, may influence the rate of the heart-beat considerably, as in the celebrated Czermak of Prague, who, by pressing upon a cervical tumour, was able to slow his heart at will. The case of the late Lieut.-Colonel Townsend is an instance of the possession of a similar power, but he did not, according to Fothergill, kill himself by the too frequent repetition of the inhibitory process. It is far more common to meet with cases in which a slight degree of slowing of the heart's action may be observed during intense thought, the passing of a strong emotion, or the endurance of great physical pain, when the effect may be said to differ little from an ordinary reflex.

Criminals and Union Infirmaries.

WE desire to draw the attention of the public to a development under the General Prisons Board that is pregnant with evil for all union infirmaries. By a new rule, convicts who are ill, especially if near the expiration of their term of penal servitude, can be, and are, removed to union infirmaries, where five shillings a week is paid for their keep. The following example of this came before the Mountmellick Board of Guardians. On December 26th last the governor of Maryborough prison sent for the Mountmellick ambulance to convey a convict from the prison to the union infirmary, the Prison Board paying five shillings a week for his keep. This convict patient, one Costelloe, had been thirty-nine years in the U.S.A.; he was convicted of forgery committed in Wexford, he was in bed for the past year, and was within a few months of the expiry of his term. That a sick convict should get proper medical advice and medicines goes without saying, but that advice and medicine should be provided within the gaol infirmary. During the past ten years the medical profession and the public have been working harmoniously together to make the workhouse infirmary less distasteful to the poor, particularly in country places. It has been suggested to remove them from the workhouse where possible and call them district hospitals. Everybody confesses that an infirmary in each union for the treatment of accidents and infectious diseases is most desirable. The action of the Prisons Board will check this movement, and will accentuate the old objections to the infirmary.

The Non-Surgical Treatment of Floating Kidney.

WHEN the risk of surgical procedures has been so greatly reduced as it has been in the last decade or two, there is a natural temptation on the part of medical men to call in the surgeon to troublesome cases that do not yield early to medical treatment. The recognition of a movable kidney as the cause of many elusive but distressing symptoms, and the difficulty of effectively dealing with the condition when diagnosed, have led to many operations for fixing the kidney to the posterior abdominal wall by one method or another. It cannot be said that the success of these procedures has been as great as was at first anticipated, and many patients have been disappointed after having undergone a severe operation to find the old condition return again in a year or two's time. Fixing the kidney by external bands and pads is usually an unsatisfactory process; though it answers well enough in some cases, in the majority it gives but slight relief. Aaron, of Detroit, writing from an experience of 442 cases, attributes the non-success of this method to want of accuracy in the making and fixing of the belts. He maintains that the proper shape and size of the belt can only be determined by the physician, whereas in practice it is usually left to the instrument maker. He says that no trouble is too great to be taken in mapping out the position, range of movement, and relations of the kidney, and that when this is done belt after belt (if necessary) must be made till the indications are exactly fulfilled. Aaron himself inflates the colon with gas to make sure that there is no coloptosis, and even takes a model of the abdomen with pliable lead to obtain the exact shape of the lower edge of the kidney—the spot where the greatest pressure should come. By taking all these precautions and getting a band that uniformly compresses the lower abdomen, with a pad pressing the displaced organ upwards and backwards, he claims to have cured 215 cases out of 442, whilst 168 improved, and 59 were either not relieved or passed from observation. If by adopting his methods similar results are obtained, a great many disappointing operations may be avoided.

Infectivity of Acute Rheumatism.

TAKEN in connection with the recent researches of Dr. Ainsley Walker and others into the causation of acute rheumatism and the study of a supposed specific organism, it is important to note every occurrence of the disease where there appears to be a direct infection from one patient to another. Just as formerly in the case of pneumonia the apparent rarity of infection was made an argument against the doctrine of bacterial origin, so nowadays with acute rheumatism. Nevertheless, there are on record several instances of outbreaks of the disease impossible to explain by any other hypotheses. One of the best instances we have seen is that recently reported by Mr. Sydney Hawthorne, of Murree, U.S.A., (*a*) in which no less than six

(*a*) *British Medical Journal*, December 26, 1903.

members of one family were struck down one after the other by acute rheumatism. The diagnosis was not open to question, as it was made in some of the cases independently, by himself and by two other physicians. Nor was the cause apparently any common condition other than infection, such as cold or damp, since the outbreak occurred in the middle of prolonged drought. We draw attention to Mr. Hawthorne's cases because we believe that in the investigation of the etiology of disease epidemiological study must go hand in hand with bacteriological, and while the latter must remain principally in the hands of laboratory workers, the former is the special field of the general practitioner.

PERSONAL.

MRS. JANE GABRIEL has presented £1,000 to Charing Cross Hospital to endow a bed in memory of her husband, the late Mr. Arnold Gabriel.

AT the next meeting of the Royal Microscopical Society, on Wednesday, January 20th, at 8 p.m., Dr. Woodward will deliver his Presidential Address on the Evolution of Vertebrate Animals in Time.

WE regret to announce the death of Mrs. Allingham, wife of Mr. H. W. Allingham, F.R.C.S., of Grosvenor Street, W., and the Orchard, Marlow, Surgeon to His Majesty's Household, at Marlow on Wednesday last.

DR. J. W. TAYLOR, F.R.C.S., Professor of Gynæcology in the Birmingham University, has been elected President of the British Gynæcological Society. Full list of office-bearers elected on Thursday last will be found in our news columns.

DURING his recent visit to Chatsworth, His Majesty the King was attended by Dr. E. M. Wrench, of Baslow. Before leaving the district, the King called at Dr. Wrench's house, and left with him a diamond pin and other souvenirs of his Royal patient.

THE retirement is announced of Dr. J. S. Wallbridge, of the Medical Department of British Guiana, on pension after twenty-seven years' service in that Colony. His district will be taken over by Dr. J. E. A. Ferguson, who has had charge of the Belfield District.

PRINCESS CHRISTIAN (the President), accompanied by Princess Victoria of Schleswig-Holstein, visited the Royal Free Hospital, Gray's Inn Road, on Wednesday afternoon last, and distributed the presents from the Christmas tree which she had provided for the patients and nurses.

ON January 7th, at St. John's, Worcester, an illuminated congratulatory address and a silver tray were presented to Dr. and Mrs. Polson. The tray bore the inscription: "Presented to Dr. and Mrs. J. Ronald Polson upon the occasion of their marriage, February 29th, 1903, by friends and patients of Dr. Polson. 'I was sick, and ye visited me.'"

DR. F. J. WALDO, Coroner for the City of London, last Thursday delivered the first of a series of six lectures on "Medical Jurisprudence" at the Old Hall, Lincoln's Inn, under the auspices of the Council of Legal Education. The next lecture of the series, to be delivered on January 21st, will have as its subject, "Birth in Relation to Civil and Criminal Law."

WE are glad to be able to announce that the long drawn out Scotch quarry dispute has at last been settled by the reinstatement of Dr. Lachlan Grant as medical officer, and the return of the quarriers to their work. The case stands out from all others on account of the prolonged stand the men made for their medical officer and their unswerving determination never to return to their work until justice had been done to him.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

EDINBURGH ROYAL INFIRMARY.—During the year that has just gone by important changes have been made in the regulations of this institution, and in that in which we have now entered it seems as though a continuance of the reforming spirit will effect still further alterations, and indirectly may have an important influence on the University and whole medical school. Hitherto the tenure of office of the physicians and surgeons has been limited to a period of fifteen years without any age limit, and the vacancies occurring have been filled up, almost as a matter of routine, from the assistant staff. Last summer the managers decided that for this arrangement an age limit, which they fixed at sixty, should be substituted; they also arranged that the senior assistant surgeon and physician, under whose care the wards reserved for the teaching of women were placed, should henceforth rank as full surgeon and physician. The rule was passed without consultation with the staff, and called forth considerable opposition from the latter, and, as a result of the action which the staff took, the rule was so far modified that the age for retiring was fixed at sixty-five instead of sixty years. The rule applied to the assistant staff and to such of the physicians and surgeons as had not yet entered the second five years of their fifteen-year period. The University Professors, too, were exempted from the operation of the rule, and as three holders of chairs act as physicians, two as surgeons, and one as a gynæcologist, a not inconsiderable proportion of the staff are thus placed at some advantage as compared with their less fortunate colleagues. At the annual meeting of the Court of Contributors, held on January 4th, when the report of the Infirmary was submitted for approval a motion—"That in the public interest the age limit enacted by the managers for the ordinary physicians and surgeons be made to apply as well to the physicians and surgeons of the institution nominated by the University"—was carried by 46 votes against 23, in favour of remitting the question to the managers for consideration and report next year. The meetings of the Court of Contributors are usually purely formal, and not largely attended, and it was probably a surprise to many of those entitled to vote at them to learn how great the power of the Court is, for it seems that, according to the Infirmary Act of 1870, the managers are bound to give effect to their recommendations. This point, however, is somewhat uncertain, and it must be left to the lawyers to decide which of two clauses in the Act, one of which provides that the managers "may adopt" recommendations of the Court, and the other of which empowers the Court to alter or make new statutes, applies in the present instance. The Committee of the Contributors, whose duty it is to examine the managers' report and to report thereon to the adjourned meeting of the Court of Contributors to be held on the

18th inst., deal with the matter in these words:—"At the meeting of Contributors held on January 4th, a motion was carried which enacted a new rule putting the Professors who hold wards on the same footing as regards an age limit as the medical and surgical officers who would be affected by the new rule framed by the managers. That new rule, although referred to in the motion as to an age limit for Professors, and therefore possibly by implication approved of by the Court of Contributors, has not been formally sanctioned by the Court, and technically it may be open to question whether the rule as to the Professors was in order in being passed." The appointment of a Joint Committee of the managers and Contributors to consider this difficult and delicate question is suggested, its serious importance requiring ample time for deliberate consideration. In this position, therefore, the matter rests at present, and pending the decision of the adjourned meeting, its discussion may be postponed.

ANNUAL REPORT OF THE ROYAL INFIRMARY.—The total number of in-patients treated was 10,484—an increase of 523, the death-rate being 7·2 as against 8.3 last year, and the cost of maintenance per occupied bed £64 1s. 3½d., a decrease of £1 0s. 7d. The ordinary income was £32,685, an increase of £64; the ordinary expenditure £47,600, an increase of £407. The difference was met from the extraordinary income of £47,002. The bathing department was opened in February, and by September 30th, 1,636 baths of various description had been given, supplying a want long felt. Fire escape staircases had been completed in all the medical blocks, and those on the surgical side improved. One of the fire-brigade is now constantly on duty in the infirmary. The Eye and Ear and Throat pavilions are now occupied, the additional sixty beds thus afforded completing the extension scheme begun thirteen years ago. The wards set free provide additional accommodation for female cases, and a much improved skin and electric department are being arranged for. The report then states the new rules, referred to above. In the report of the Contributors on the above report the only clause of importance, apart from that dealing with the age limit, is one requesting information from the managers on the proposal to institute wards for mental cases, and hoping that the matter will be dealt with.

BELFAST.

BELFAST CORPORATION.—At a meeting of the Public Health Committee of this Corporation last week, Dr. James Graham resigned the chairmanship of the committee, which he has held for thirteen years, and also his membership of the committee. Speeches were made expressing the sorrow of his colleagues at his retirement, and referring to his genial and kindly disposition. These compliments were well deserved, but, unfortunately for the City, it is not geniality and kindness which are now required in the Public Health Department. What we badly need are the qualities that have made Lord Kitchener so successful, and until we get someone who is at least a faint likeness to that type, we must expect municipal jobbery and corruption to flourish, and with them the typhoid bacillus.

THE FOOD AND DRUGS ACT.—An interesting prosecution under this Act took place at Ballymena last week, which has attracted much notice. The defendant was nominally a tradesman in the town, but in reality the action was against a large Glasgow manufacturing firm, who supplied the article in question, known and sold as "cooking fat." This was admitted to be a manufactured article, containing about 20 per cent. cottonseed oil. The inspector of foods and drugs withdrew the "injurious to health" clause in the summons. One of the partners in the Glasgow firm testified that they had manufactured cooking fats for thirty years, and sold them under various names, and that last year they used no less than twelve thousand tons of cottonseed oil. After several experts had been heard, the Bench dismissed the case, holding that the Act had not been contravened.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE HOME OFFICE AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I wisn to call your attention to a recent correspondence between the Criminal Department of the Home Office and Mr. Collinson, the Secretary of the Humanitarian League, and to draw some consequences therefrom. The principles involved in the final answer of Mr. Chalmers are not new. They appeared in the *Fortnightly Review* for September, 1899, in an article evidently from the pen of an official; but as it was anonymous sufficient attention was not paid to it. The present case was as follows:—In the year 1899 an Act of Parliament was passed which rendered it illegal to sentence any child to imprisonment followed by detention in a reformatory. In 1903 the magistrates at Bishop Auckland sentenced a boy named William Ferguson to imprisonment followed by detention in a reformatory. They seem to have discovered their blunder very speedily and informed the Home Secretary, who thereupon remitted the remainder of the imprisonment (the sentence having been for a month), and directed the boy to be sent to the reformatory at once. The illegality of this sentence does not seem open to question. I do not know what term the boy actually spent in prison, but supposing it to have been forty-eight hours, a sentence of forty-eight hours' imprisonment followed by three years' detention in a reformatory would have been as illegal as that actually passed.

Mr. Collinson having called attention to the illegality—the combination of imprisonment and detention in a reformatory being illegal, irrespective of the actual duration of either or both punishments—Mr. Chalmers ultimately replied on behalf of the Home Secretary that questions of legality could only be decided in a court of law, whereas the Home Secretary's function was to advise the King with regard to the exercise of his prerogative of mercy, which prerogative had been exercised by shortening the duration of Ferguson's term of imprisonment. (Notwithstanding this shortening, the punishment which is being inflicted under the authority of the merciful Home Secretary is, as already intimated, in excess of what the law permits.)

Of course, after this, the Criminal Department of the Home Office should not be regarded as in any sense a Court of Criminal Appeal. It does not concern itself with questions of law or justice. Its function is merely—taking the sentence as it finds it, and without inquiring into the legality either of it or of the trial which resulted in it—to consider whether there are grounds for showing mercy to the prisoner and remitting the sentence, either wholly or in part. Now, this being so, of what use is legal knowledge on the part of the permanent officials? Why should they be selected (chiefly, at least) from the members of the legal profession? Questions of law are quite outside the Home Secretary's province, and, it may be added, that if any question of law did accidentally arise, there are high legal functionaries whom the Home Secretary could always consult free of charge. Knowledge of law is no guide in the exercise of mercy. But one of the strongest grounds for merciful interposition is the mental condition of the prisoner, which may vary from perfect responsibility to complete insanity (or idiocy), with a different degree of culpability at every stage. Who ought to advise the Home Secretary as to the exercise of mercy in such cases? Certainly not a barrister, who may be prejudiced in favour of the legal view of insanity which is scouted by the medical profession, or may, at least, be apprehensive of undermining this legal view by the too frequent exercise of mercy towards persons who are legally sane. The best advisers for the Home Secretary in such cases would be qualified medical gentlemen who had paid special attention to the subject of mental deficiency

and disease. And another kind of case frequently occurs in which the services of permanent medical officials would be equally valuable. Take, for example, the famous Maybrick case. We do not know what medical gentlemen the Home Secretary consulted. We do not know what statement of the case was laid before them, or whether they were left to read such newspaper reports as they happened to have in their possession; and we do not know how their opinions were divided and whether they were of a positive or of doubtful character. Now, although it would be undesirable to have such questions settled by one or more permanent officials, their services would otherwise prove of the utmost value. They would know the names of the specialists whose opinions should be obtained in such a case as that before them. They would see that a full and correct statement of the evidence bearing on the medical issues was sent to every doctor who was thus consulted. They would be able to explain the meaning of each reply received, which in some cases might contain enough technical language to puzzle the Home Secretary and his assistants; and they would also be able to point out whether any of the doctors had mistaken the evidence or based their opinion (wholly or in part) on matters which were not in evidence. The present system affords no security that any of these things will be done.

I therefore maintain that the highest officials in this department should not be barristers, but members of the medical profession. The Home Secretary is much more concerned with medical than with legal questions, and as regards the latter, he is abundantly supplied with extern assistance.

I am, Sir, yours truly,

A BARRISTER.

[The clear and powerful enunciation of our correspondent calls attention to a matter upon which the full weight of medical authority has never been adequately expressed. For centuries past law has failed to understand medicine.—ED.]

Obituary.

HENRY BOYD CARDEW, M.R.C.S., ENG., L.R.C.P. LOND.

WE regret to announce the death of Mr. Henry Boyd Cardew, of Cheltenham, at the early age of thirty-seven years, after a short illness. He was the elder son of Major-General Henry Cardew, a retired officer of the Royal Artillery. Upon leaving Cheltenham College, where his early education was received, he entered at St. Bartholomew's Hospital and eventually took the diplomas of the Royal College of Surgeons of England and the Royal College of Physicians of London in 1890. Returning to Cheltenham he commenced general practice in 1894. But he continued for several years later to hold the position of honorary medical officer to the branch dispensary of the hospital and to the Victoria Home. He was married in 1895 to Miss Agnes Moore, third daughter of the late Mr. Thomas Moore, F.R.C.S., of Blackheath, and leaves a widow and four daughters. The deceased was a well-known figure in the local athletic and social world, and his early death will be the cause of wide-spread regret.

DR. DETWEILER, OF KRÖNBERG.

A TELEGRAM from the Berlin correspondent of the *Standard*, announces the death of Privy Councillor Dr. Peter Detweiler, who died suddenly, at Krönberg, aged sixty-six. The deceased was well known in connection with his open-air treatment of tuberculosis.

DR. E. C. GARLAND.

THE sudden death was announced on the 10th instant of Dr. E. C. Garland, the Medical Officer of Health for the borough of Yeovil. He had attended a meeting of the Town Council in the afternoon, and was afterwards chatting in the Municipal Offices, when he was taken ill. He was carried home in a cab, and expired shortly afterwards. Deceased, who was sixty-nine years of age, had held the post of medical officer since 1871 or 1872, and was greatly interested in all movements for the welfare of the town. Of late years he had retired from general practice, although he continued to carry out his official duties. Deceased leaves a widow and a son and daughter, the former being Mr. C. A. S. Garland, a barrister on the Western Circuit, and Recorder of Winchester.

SIR WILLIAM RAYMOND KYNSEY, M.D., J.P., C.M.G.

SIR WILLIAM RAYMOND KYNSEY, late Principal Civil Medical Officer and Inspector General of Hospitals in Ceylon, died at his residence, Courtenay House, Horsham, on Monday week, in the sixty-fourth year of his age. Son of the late Dr. Thomas Brett Kynsey, M.D., J.P., of Athy, co. Kildare, he was born in 1840, was educated at Trinity College, Dublin, and was admitted a Licentiate of the Royal College of Surgeons, Ireland, in 1861, and of the Royal College of Physicians, Ireland, the following year. He joined the Medical Service of the Army in September, 1863, and served in the Ashantee War of 1873-4, when he was present at the capture of Coomassie, for which he had the medal. In 1875 he was placed on half-pay on appointment as Principal Civil Medical Officer in Ceylon, and in 1886 after having been admitted a member in 1880, was elected a Fellow of the Royal College of Physicians, Ireland. He held his official appointment in Ceylon until 1899, and while resident there filled various other offices, including that of a member of the Legislative Council, a Magistrate, a visitor of the gaols of the Island, and a Municipal Councillor of Colombo. He was decorated with the C.M.G. in 1888, and was Knighted in 1897. Sir W. Kynsey married, in 1866, Isobel Keith, daughter of the late Captain J. K. Jolly, of the East India Company's Service, of Farieland, Kandy, Ceylon.

LIEUTENANT J. R. WELLAND, R.A.M.C.

WE deeply regret the death of a promising member of the Royal Army Medical Corps in the recent battle at Jidballi in Somaliland briefly referred to last week. Lieutenant Welland was one of three officers killed at that engagement, and no further particulars have as yet reached home other than that he was killed by a spear thrust. Lieutenant Welland graduated in Dublin University in the year 1900, and entering the Royal Army Medical Corps was shortly after sent to Somaliland where he served with the 6th Batallion of the King's African Rifles. Last year he was invalided home, but returned again to Somaliland in the autumn. Welland was a well-known athlete during his student career in Trinity College, and stroked the Dublin University eight on many occasions, notably in their contest with the Pennsylvania crew in 1901. He leaves a widowed mother to whom we offer our deep sympathy.

Society for Relief of Widows and Orphans of Medical Men.

AT the quarterly court of the directors of this society, held on Wednesday last, the president, Mr. Christopher Heath, in the chair, three new members were elected, and the death of a member reported. There were no fresh applications for grants. It was resolved to distribute £1,315 among the 53 widows, 15 orphans, and 4 recipients from the Copeland Fund, now in receipt of grants. A sum of £580 had been given at Christmas as a present, £10 each to 53 widows, £3 each to 12 orphans, and £5 each to the 4 orphans on the Copeland Fund. The expenses of the quarter were £77 12s. 6d.

THE increasing use of oxygen for medical purposes renders it desirable for every practitioner to have an address at hand to send to in case of emergency. The well-known makers of oxygen, Messrs. Brin and Co., who may indeed, be called the pioneers of that particular trade, have issued a remarkably neat little pocket diary which contains their *new* address. Much useful information as to oxygen is appended to this handy little book.

Literature.

VON NOORDEN ON THE PATHOLOGY AND THERAPY OF DISEASES OF METABOLISM AND NUTRITION. (*a*)

THESE little monographs constitute a most welcome addition to the library of the physician. They are clearly and boldly written, are the result of prolonged scientific work and contain much that is new, and in places even revolutionary. The monograph on nephritis is, perhaps, the most interesting, and in it the writer calls in question almost all the usually accepted notions on the therapy and treatment of this serious organic disease. The translator has done his work well, although here and there the book is disfigured by mistakes. It is by no means easy to say how many of these are intentional and how many accidental. On the same line we find the two remarkable words, "edema" and "perenchymatous." It may be that both are intentional, as we understand that the new American system of orthography sanctions the use of the word "edema," while the American mode of phonation sanctions the use of the word "perenchymatous." If, however, the mispelling of these and other words is intentional, so far as the American editor is concerned, we must protest against English publishers publishing in their own name such American works as are written in Americanese without first translating them into English.

This condemnation of a practice which is becoming too common must not be read as an unfavourable criticism of these little monographs. So far from regarding their subject-matter unfavourably, we cordially recommend them to medical men, as they will enable the latter to review from an entirely new standpoint their ideas on the subjects of which the books before us treat.

MUTER'S ANALYTICAL CHEMISTRY. (*b*)

The ninth edition of this work, which must be regarded as the most valuable one of moderate price for the use of students, has been brought well up to date and will continue to be one of the most widely used books by pharmaceutical students.

It is really astonishing to note the enormous amount of information that has been collected in a book of handy size. After a detailed search we can hardly find any article of consequence on which there is not useful and up-to-date information. In addition to this, the facts dealt with are not presented in such a manner as to require isolated feats of memory, but follow in a logical and understandable manner so that the students' ideas and capacity are enlarged as he proceeds.

We can find very little that calls for criticism in the book, excepting some of the illustrations. Those which are intended to give an idea of the various urinary deposits are by no means distinct and appear to have been damaged, and the author would do well to replace them in the next edition.

The only other point to which exception can fairly be taken is the author's very brief treatment of the important subject of water analysis. Such treatment is undoubtedly likely to produce in the mind of the student an impression that the subject is one which may be mastered in a few days, and is not a subject which requires years of patient study. A little less than a page is devoted to the interpretation of results, which is so inadequate that it would have been better omitted altogether, or a statement might have been added showing the impossibility of treating the subject in the space at the author's disposal.

With this exception we have nothing for the work but unqualified praise, and feel assured that this edition will meet the success that so useful a work deserves.

(*a*) "Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition." By Dr. Carl von Noorden, Senior Physician to the City Hospital, Frankfurt. Authorised American Edition. Translated under the direction of Boardman Reed, M.D. Part I., Obesity. Part II., Nephritis. Part III., Membranous Catarrh of the Intestines. New York: E. B. Treat and Co. 1903.

(*b*) "A Short Manual of Analytical Chemistry." By Dr. J. Muter. F.I.C., F.R.S.E., &c. Pp. 250, with 56 illustrations. Demy 8vo, price 6s. net. London: Bailliere, Tindall and Cox.

HOME NURSING (*a*)

VERY appropriately, indeed, "This Book is Dedicated to all Women who are Desirous of Alleviating the Sufferings of their Fellow-Creatures." As the author tells us, the volume was "written in the hope that it may be of service in guiding an untrained nurse in her duties when administering to the sick and dear ones at home." On this account the endeavour has, of course, been made according to the author's discrimination "to state all those facts which a lay person should know if she desires to be efficient in home nursing. At the same time, care has been taken not to burden her with superfluous knowledge." It is needless to add that the author's self-imposed task is one of exceptional difficulty—one which no two members of the profession would be at all likely to carry out along strictly parallel lines; and, accordingly, one regarding the merits of whose accomplishment as now placed before all readers, no two would be likely to form opinions strictly coincident. The chapters are ten in number: "Home Nursing," "The Sick Room," "Sick-Room Régime," "Elementary Human Anatomy and Physiology," "Some Diseases and their Nursing," &c. The author writes clearly and concisely, and gives a good deal of sound common-sense advice. Needless to say that the net resultant value of the book will depend largely on the individual hands in which it is placed; on the collateral circumstances and environments, &c., &c. We think that, upon the whole, however, the author has done his part well. There are fifteen illustrations, and an index.

MANUAL OF PRACTICAL ANATOMY. (*b*)

EVEN such a finite science as anatomy undergoes a process of development, otherwise no fresh edition would be necessary, mere reprints sufficing for all requirements. On the one hand there is a process of evolution which finds expression in the elimination of unimportant details and superfluous verbiage; on the other our conceptions in regard to the anatomical relationships of tissues and viscera are modified and the text embodying those conceptions has to be remoulded. Both these processes have been at work in the gestation of the volumes now before us, with results which we doubt not will be to the advantage of the student.

It is a matter for congratulation that anatomists are getting to recognise the line of demarcation between what we may call academical anatomy and the practical details which alone are likely to prove of service to the future practitioner—physician or surgeon as it may be. The method of investigating the relationship of the internal organs by the aid of frozen sections has yielded brilliant and unexpected results, of which full advantage has been taken by the author. There too, the anatomist exercises a freer hand in describing these relations since, in respect of the hollow viscera at any rate, they vary within tolerably wide limits in the human organism in deference to physiological circumstances. and it is obviously absurd to invite the student to study one facet of the subject to the exclusion of the others, in other words, the tendency is to make anatomy a vital rather than a merely cadaveric study. In this direction radiography has contributed its quota of actual observation and is likely to extend its sphere of usefulness in the near future.

One noteworthy feature in this edition is the disappearance of many old friends in the shape of illustrations, some of which were more or less mouldy with age. Their successors are unquestionably superior from an artistic as well as from an anatomical point of view, much of the credit being due to Mr. J. T. Murray, who, as the author observes, has obtained an almost unrivalled reputation in the treatment of anatomical subjects. The result of the collaboration is a work

(*a*) "Home Nursing." By Bernard Myers, M.D., C.M., M.R.C.S., L.R.C.P.: etc, Lecturer and Surgeon to St. John Ambulance Association. London: Bailliere, Tindall and Cox. 1903. Crown 8vo., pp. 131. Price 2s. 6d. net.

(*b*) "Manual of Practical Anatomy." By D. J. Cunningham, M.D.Edin. and Dublin, D.Sc., LL.D., D.C.L.Oxon., F.R.S., Professor of Anatomy in the University of Edinburgh, &c. Third Edition, 2 vols. Edinburgh: Young J. Pentland. 1903.

which will perpetuate the fame of its author and command the attention of students.

Medical News.

Visitation at Queen's College, Galway.

A VISITATION of the Queen's College, Galway, was held on Saturday last. The visitors attending were the Right Hon. Lord Clonbrock, K.P. (in the chair); the Right Rev. the Lord Bishop of Tuam, the Right Hon. the Earl of Westmeath, Sir A. V. Macan, President of the Royal College of Physicians, Ireland; and Sir Lambert H. Ormsby, President of the Royal College of Surgeons, Ireland. The President of the College, Professor Alex. Anderson, LL.D., and other professors attended. The principal business which was brought before the visitors was an appeal by Professor Pye against the decision of the College Council in the case which he had brought forward, in that the Roman Catholic students of the College had been sent tracts by a Protestant clergyman. The College Council declined to accede to Professor Pye's request for an inquiry into the circumstances. Professor Pye, having spoken in favour of his appeal, the President said that this case had occurred in December, and that there had been no repetition of it, and that, moreover, the clergyman who had distributed the tracts had undertaken not to do so again. Under the circumstances, and after hearing the expression of disapproval from the visitors, Professor Pye withdrew his appeal for a public inquiry. We are glad that he consented to such a course. Religious animosity is quite sufficiently keen in Ireland without professional men lending themselves to its aid. We have no sympathy with or approval for any form of proselytising by any religion, but the fact cannot be overlooked that conscientious men of every religion often consider it to be their duty to attempt to proselytise. Such attempts cannot be permitted to be made on those who are, or may be, unduly prone to be affected by them, although the more strong-minded are quite capable of looking after themselves. For this reason Professor Pye's protest was most proper, though a public inquiry into such an incident would have been out of place. The visitors then proceeded to inspect the laboratory, museum, and other parts of the College. They then returned to the examination hall, when Lord Clonbrock, the chairman, said that the visitors were unanimously of opinion that everything was in extremely good working order in all the departments, considering the limited space at present available. The chairman also stated that it was the unanimous opinion of the visitors that, as their was no Chair of Pathology in the College, the council should make arrangements for the appointment of a suitable lecturer in pathology, who should devote the whole of his time to the subject.

Pharmaceutical Society of Great Britain.

AN educational meeting will be held in London in the Lecture Theatre on Wednesday, January 20th, at 3 o'clock. (I.) "University Education for Pharmacists." By Professor R. B. Wild, M.D., M.Ch. (II.) "Concurrent Curricula." By H. Whippell Gadd.

A London "Herbalist's" Business.

JETHEL LARDENT and Ada Booth were found guilty of being concerned together in performing an illegal operation on a woman named Mitchell, and were each sentenced to five years' penal servitude. The male prisoner carried on the business of a herbalist in Southwark Park Road, and it was stated that the police had received numerous complaints as to what went on at the premises. The jury recommended the prisoners to mercy on the ground that the woman upon whom the operation was performed was an accomplice.

University Candidates for the Army.

A SCHEME recommended by the Advisory Board of Military Education and approved by the Secretary of State for War has been published by the War Office regarding the appointment of candidates from the universities to commissions in the regular forces. The scheme will come into operation in September next. Its object is to attract this class of candidates into the army by doing away as far as possible with the disadvantage under which university candidates who have completed their university career by taking a degree at present labour in having to enter the army at a later stage than men who are not university graduates. The great importance of this announcement to 'varsity men is obvious.

British Gynæcological Society.

AT the annual meeting of this Society on Thursday last, January 14th, the election of the officers and council resulted in the following appointments. The asterisk indicates the new officers:—

Hon. President.—R. Barnes, M.D., F.R.C.P. (Eastbourne).

President.—*Professor J. W. Taylor, M.D., F.R.C.S. (Birmingham).

Vice-Presidents.—E. Stanmore Bishop, F.R.C.S. (Manchester), Professor Murdoch Cameron, M.D. (Glasgow), *F. B. Jessett, F.R.C.S. (London), *Sir A. V. Macan, M.D., P.R.C.P.I. (Dublin), H. Macnaughton-Jones, M.D., F.R.C.S.I. (London), J. A. Mansell-Moullin, M.A., M.B., M.R.C.P. (London), Christopher Martin, M.B., C.M., F.R.C.S. (Birmingham), F. F. Schacht, B.A., M.D. (London), Professor Alfred Smith, M.B., F.R.C.S.I. (Dublin), *Heywood Smith, M.A., M.D., M.R.C.P. (London), *W. D. Spanton, F.R.C.S. (Hanley), *W. Travers, M.D., F.R.C.S. (London).

Treasurer.—W. H. Slimon, M.D., F.F.P.S. (London).

Council.—G. R. Carter, M.R.C.P.I. (London), Eber Chambers, M.D., M.R.C.S. (London), R. J. Colenso, M.A., M.D. (London), Sir J. H. Croom, M.D., F.R.S.E., F.R.C.P., F.R.C.S.E. (Edinburgh), T. M. Dolan, M.D., F.R.C.S. (Halifax), *W. Duncan, M.D., F.R.C.S. (London), F. Edge, M.D., M.R.C.P. (Wolverhampton), *G. Elder, M.D. (Nottingham), *T. J. English, M.D. (London), Bedford Fenwick, M.D., M.R.C.P. (London), *J. Haig Ferguson, M.D., F.R.C.P. (Edinburgh), Clement Godson, M.D., M.R.C.P. (London), Arthur Helme, M.D., M.R.C.P. (Manchester), James Jardine, M.B., C.M. (Richmond), Henry Jellett, M.D., F.R.C.P.I. (Dublin), *J. MacPherson Lawrie, M.D. (Weymouth), *R. P. Ranken Lyle, M.D. (Newcastle-on-Tyne), *S. Lloyd, M.D. (London), *J. Padman, M.R.C.S. (London), Mayo Robson, F.R.C.S. (London), Charles Ryall, F.R.C.S. (London), R. T. Smith, M.D., M.R.C.P. (London), Herbert Snow, M.D. (London), *H. F. Vaughan-Jackson, M.R.C.S., L.R.C.P. (Potter's Bar).

Editor of the Journal.—J. J. Macan, M.A., M.D. (London).

Hon. Secretaries.—J. H. Swanton, M.A., M.D. (London), S. Jervois Aarons, M.D. (London.)

Auditors.—C. H. Bennett, M.D. (London), F. A. Purcell, M.D. (London.)

Trustees of the Property of the Society.—G. Granville Bantock, M.D., R. S. Fancourt Barnes, M.D., F.R.S.E., Clement Godson, M.D., M.R.C.P.

Industrial Diseases Due to Poison.

THE first of a series of lectures on "Public Health" was given in the Library of the Owens College, Public Health Laboratory, Manchester, by Professor Thomas Oliver, of Newcastle-on-Tyne. The subject was industrial diseases due to certain poisonous fumes or gases, and the lecturer dealt principally with those caused by phosphorus, bisulphide of carbon, carbon monoxide, and sulphuretted hydrogen. Dealing with phosphorus poisoning in match manufactories, he pointed out that after making extensive inquiries about six years ago he had to report to the Home Office that absolute immunity from that poisoning could not be guaranteed so long as white phosphorus was used. Such poisoning had now considerably diminished, and match making had ceased to be a dangerous trade by the substitution of a less harmful material for white phosphorus. Speaking of poisoning by sulphuretted hydrogen, he said he did not think members of the medical profession were sufficiently alive to the danger of inhaling it, and instanced several cases in which death had resulted almost instantaneously from such inhalation.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

"THE PHARMACOPŒIA DIGEST."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Kindly allow me to correct a slip in the last paragraph of your editorial appearing in your issue of January 13th, in which you refer to me as compiler of the digest recently prepared by Mr. Wm. Chattaway for the Pharmacopœia Committee of the General Medical Council. I gave Mr. Chattaway assistance in collecting and arranging references, but there my responsibility ends.

I am, yours obediently,
C. G. MOOR.

[The error on the part of the writer of the leader was obvious. He had already alluded to Mr. Chattaway as the author of the "Digest," and intended simply to mention Mr. Moor's book on "Standards" as one of the secondary sources of information.—ED. MEDICAL PRESS AND CIRCULAR.]

MR. J. S.—The X-rays are more generally employed in the treatment of disease in America than in this country, and, for example, according to one authority acne is more effectively treated by this method than by any other.

PENSATOR.—The MS. which our correspondent submits for approval, while dealing with important truths, is still, we think, more adapted for a student's journal than for our columns.

EXAMINATION FOR THE "CONJOINT."

"NAME the bones of the skull." The candidate, hesitating, stammers, "Excuse me, sir, it must be my nervousness; but for the life of me I can't remember a single one——Yet I have them all . . . in my head."

F.R.C.S.—Our correspondent's letter has been handed on to the writer of the article as requested.

MISS K. (Glasgow).—We have been unable to trace the report in our columns.

DR. S. F. W. (Paris).—The request you make is not exactly in accordance with our editorial capacity, but we have handed your letter to a practitioner who is in a more likely position to concede the favour you ask.

SMILAX (Ealing).—We hold it to be the duty of every medical man to become a member of one of the Defence Societies. The Medical Defence Union is the oldest of those admirable institutions, but the choice between that and the others must be left to your own judgment.

HOSPITAL REFORMER (Leicester).—The Hospital Sunday Fund wields a vast power over hospitals by its method of making grants, subject to certain conditions. The chief objection to this method would be removed if the reasons for the conditions were clearly stated in each individual case. At present the complaint is not infrequently made that the demands are arbitrary and indefensible. As the administrators of public charity the principles of the Sunday Fund should be clearly laid down, and, if necessary, some sort of arbitration be obtainable where the justice or expediency of its decisions is called in question.

Appointments.

BARKER, F. J., M.B., C.M.Glasg., Clinical Assistant to the Chelsea Hospital for Women.

BARWELL, HAROLD, M.B.Lond., F.R.C.S.Eng., Assistant Surgeon to the Metropolitan Ear, Nose, and Throat Hospital, Grafton Street, Fitzroy Square.

BONNEY, W. F. VICTOR, M.S., M.D.Lond., F.R.C.S.Eng., M.R.C.P. Lond., Lecturer in Practical Midwifery in the Middlesex Hospital Medical School.

CANDLER, GEORGE, B.A.Cantab., L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer and Public Vaccinator for the Black Torrington, Bradford, and Cookbury Districts of the Holsworthy Union (Devon).

EMANUEL, J. G., M.D.Lond., M.B., Ch.B.Birm., M.R.C.P.Lond., Physician to Out-patients at the Birmingham and Midland Free Hospital for Sick Children.

GRANT, LACHLAN M.D., C.M.Edin., re-appointed Medical Officer to the Ballachulish Quarriers' Medical Club, *vice* A. Dingwall Kennedy, M.B., Ch.B.Glasg., resigned.

GREY-EDWARDS, H., M.B., B.Ch.Dub., Honorary Ophthalmic Surgeon to the Carnarvonshire and Anglesey Infirmary.

LISTER, W. T., B.A., M.B., B.C., F.R.C.S., Assistant Surgeon to the Royal London Ophthalmic Hospital, City Road, E.C.

MACKENZIE, E. G., M.B.Toronto, Clinical Assistant to the Chelsea Hospital for Women.

MILWARD, F. VICTOR, B.A., M.B., B.C Cantab., F.R.C.S.Eng., Surgeon to Out-patients to the Birmingham and Midland Free Hospital for Sick Children.

NORMAN, R. H., M.D.Lond., B.S., M.R.C.S., L.R.C.P Lond, Assistant Anæsthetist to the Great Northern Central Hospital.

PRICE, E. O., M.D., C.M.Edin., Honorary Medical Officer to the Carnarvonshire and Anglesey Infirmary.

STAMM, L. E., M.D., B.A., B.Sc.Lond., Medical Officer to the British Home and Hospital for Incurables, Streatham Common, S.W.

THORNTON, BERTRAM, M.R.C.S., L.R.C.P.Lond., J.P., Medical Officer of Health of the Borough of Margate.

Vacancies.

Bradford Poor-law Union.—Resident Assistant Medical Officer. Salary £125, with rations, apartments, and washing. Applications to Geo. M. Crowther, Clerk to the Guardians, 22 Manor Row, Bradford.

Clogher Union.—Medical Officer. Salary £70 per annum, with registration and vaccination fees; also to act as Medical Officer of Health at a salary of £10 10s. per annum. Immediate application to Thomas Turner, Clerk of Union. (See advt.)

Darenth Asylum (Training School and Industrial Colony), near Dartford, Kent.—Medical Superintendent. Salary £600 per annum, together with unfurnished house, coals, light, washing, milk, and vegetables. Applications to T. Duncombe Mann, Clerk to the Board.

Dr. Steevens' Hospital, Dublin.—Assistant Physician and an Assistant Surgeon. Applications to the Secretary. (See advt.)

Dr. Steevens' Hospital, Dublin.—Anæsthetist. Applications to the Secretary. (See advt.)

Gorey Union.—Medical Officer. Salary £120 per annum, with registration and vaccination fees; also to act as Medical Officer of Health at a salary of £15 a year. Applications to R. Creighton, Clerk of Union. (See advt.)

Liverpool Dispensaries.—Head Surgeon. Salary £300 per annum with board and apartments. Applications to Sam. B. Leicester, Secretary, 66 Vauxhall Road, Liverpool.

Locum Tenens to do duty as Dispensary Medical Officer, &c. Salary £3 3s. per week all found. Applications to Dr. M. F. Brady, Carnew, Co. Wicklow. (See advt.)

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per anuum, with board and lodging. Applications to Secretary of the Faculty.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing. Applications to the Secretary, 24 Friar Lane, Leicester.

Norfolk and Norwich Hospital.—Lady Superintendent. Salary £100 per annum, with apartments, board, and laundry. Applications to the Secretary.

Royal Buckinghamshire Hospital, Aylesbury.—Resident Surgeon. Salary £100, with board and furnished apartments. Applications to Geo. Fell, Secretary, Rickford's Hill, Aylesbury.

St. Mary's Hospital, Paddington, W.—Casualty Physician. Salary £75 per annum. Applications to Thomas Ryan, Secretary.

York County Hospital.—House Physician. Salary £100 per annum, with board, residence, and washing. Applications to Frederick Neden, Secretary and Manager, York.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 20th.

ROYAL MICROSCOPICAL SOCIETY.—(20 Hanover Square, W.).—8 p.m. Presidential Address: On the Evolution of Vertebrate Animals in Time.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury Square, W.C.). 3 p.m. Educational Meeting. Papers:—Prof. R. B. Wild: University Education for Pharmacists. Mr. H. W. Gadd—Concurrent Curricula.

THURSDAY, JANUARY 21st.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Dr. J. E. Squire—Pulmonary Cavities—II., Treatment (illustrated by cases). (Post-Graduate Course.)

FRIDAY, JANUARY 22nd.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

MONDAY, JANUARY 25th.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20 Hanover Square, W.).—8 p.m. Casual Communications—Mr. Sefton Sewill, L.R.C.P., M.R.C.S., L.D.S.Eng. A paper will be read by Mr. F. J. Bennett, M.R.C.S., L.D.S.Eng.

Deaths.

MAXFIELD.—On Jan. 16th, at Ealing, Middlesex, the wife of James Morris Maxfield, Admiralty, and daughter of the late J. H. Simpson, M.D. Cantab., Pontefract.

MERRYWEATHER.—At Gorakhpur, India, of congestion of the lungs, Percy William, second son of the late Dr. Merryweather, of Guisborough, Yorkshire, age 37.

WILLIAMSON.—On Jan. 15th, at Southsea, Mary, relict of John Williamson, Esq., M.D., of Graham's Town, S. Africa.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CXXVIII. WEDNESDAY, JANUARY 27, 1904. No. 4.

Original Communications.

NOTES ON THE APPEARANCE OF A RASH FOLLOWING THE REMOVAL OF TONSILS AND ADENOIDS.

By WYATT WINGRAVE, M.D.Durh.,

Physician to the Central London Throat and Ear Hospital; President of the British Laryngological, Rhinological, and Otological Association.

ATTENTION to the incidence of a rash following these now popular operations was first drawn by the writer in May, 1901, (*a*) when twenty-six cases were reported as having been seen during the period of seven years. The interest and importance of such a suspicious phenomenon encouraged further research as to its frequency and nature. The results of the succeeding two and a half years' observations are now given with the hope of throwing further light upon the matter.

The patients, as before, were seen on the eighth day after the operation, or, in case of non-attendance, their parents reported that they were detained at home on account of a rash which they thought "might be something catching." Whenever possible, however, the case was personally investigated. Some of the cases were brought during the first week when the rash was developing.

So far, the search has afforded thirty-five additional cases, occurring in about 2,000 operations, a proportion which fully confirms the belief originally expressed that systematic examination would probably reveal a greater frequency than was then recorded.

The following list gives a present total of 61 cases, including the original 26. In analysing it the principal features will first be discussed collectively; those cases possessing special points of interest will then be treated individually.

Age.—The youngest patient was 14 months, while the oldest was 23 years of age, the greater number being under 10 years, *viz.*, 21 under 5, and 25 between 5 and 10.

Sex.—With regard to sex, females strikingly predominated, in the proportion of 40 to 16 males, figures which do not conform to the relative numbers of the sexes operated upon.

Nature of Operation.—In 27 cases both tonsils and adenoids were removed; in 22, adenoids only; and in 12, tonsils only.

Rash.—The rash *appeared* for the most part on the second or third day (48 instances); five times it occurred on the fourth, once on the fifth, twice on the sixth, twice on the seventh, and once on the thirteenth day.

Its *duration* was generally between two and four days, the maximum being eight days, of which there were two examples.

The *character* was decidedly polymorphous in its grouping; the spots were bright red, discrete yet often crowded, with and without erythematous swelling. The parents' own descriptive words are recorded in some of the cases, and these fairly represent the appearance of those which were personally inspected. In one case only was it urticarial.

As to *distribution*, it was found chiefly upon the chest and abdomen, sometimes involving neck, face, back, and extremities—in fact, the whole body. In most cases there was considerable itching.

It terminated in every instance without any apparent desquamation.

Constitutional Signs.—Excluding the specific, all these cases which were personally inspected, or that information was given by their medical attendant, with one exception, the temperature did not exceed 101° F. at any time, and only remained up for about forty-eight hours. The majority did not exceed 99·5. There was in many an appreciable degree of malaise and irritability, some slight vomiting, a dryness of skin, and "hot head," but no marked or severe constitutional disturbance. They were generally reported as being well and lively, and but for the rash, no anxiety would have been felt.

None afforded evidence of albumin or globulin in the urine.

Bacteriological examinations were made in most of the cases, the prevailing micro-organisms proving to be diplococci, staphylococci, and streptococci, in their order of frequency, and no evidence was afforded of any specific micro-organism.

Hæmatological examinations showed a distinct leucocytosis, but not more marked than in those who were not subject to rash. The white cells rarely exceeded 10,000 per c.mm. At the early stage (fourth to eighth day after operation) the mononucleated lymphocyte type were very marked, but later on, after the first week, multinuclear leucocytes became relatively more numerous.

REMARKS ON CASES OF SPECIAL INTEREST.

No. 3.—Had a temperature of 102° F. for twelve hours, but with no other sign of constitutional disturbance.

No. 5.—Developed diphtheria.

(*a*) "Tonsillotomy Rash." By Wyatt Wingrave, M.D. *Lancet*, August 31st, 1901.

No. 8.—Was scarlet fever.

No. 11.—Patient was suffering with chronic suppuration of middle ear at the time of operation, and developed scarlet fever.

Nos. 15 and 17.—Also subjects of chronic middle ear suppuration.

No. 24.—Scarlet fever.

No. 28.—The only case of urticaria.

No. 32.—The tonsils sloughed, were very painful, and did not heal until the fifteenth day after operation.

No. 34.—Rash persisted till the fourteenth day, but patient seemed quite well in other respects and there was no "peeling."

No. 35.—Turbinotomy was performed at same time, and there was some slight febrile disturbance, temperature being 100° for two days.

Nos. 37 and 40.—Operation was followed by acute suppuration of cervical glands.

No. 43.—Developed scarlet fever.

No. 44.—Diagnosed as surgical rash by own medical attendant. Temperature 100·5° for twenty-four hours.

No. 48.—Was thought to be scarlet fever by own medical attendant, but when seen on the eighth day after operation was quite well, free from rash, and no "peeling."

No. 49.—Subject of chronic suppurating middle ear.

No. 50.—Followed by acute suppurating middle ear.

	Age.	Sex.	Nature of Operation	App. of Rash.	Dur. of Rash	Character of Rash.	District of Rash.	REMARKS.
1	5	F	T-A	2	3	rough papular	trunk and face	Severe itching and malaise.
2	6	F	A	3	3		chest	Well.
*3	6	M	T	2	2	rosy papules	face, trunk, extremities	T. 102, itching, well.
4	4	F	T	3	4	roseola	legs, face, chest	Itching, no const. dist.
*5	3	F	A	2	4		chest	Developed diphtheria.
6	4	M	A	4	3		trunk	
7	5	M	A	4	2		chest, abd.	
*8	8	F	T-A	2				Scarlatina.

No. 51.—The tonsils sloughed, and did not heal until fifteenth day.

No. 54.—There was severe general jaundice with slight malaise, only lasting fourteen days.

No. 59.—Removed to observation ward of fever hospital as suspected scarlet fever, but did not develop any serious constitutional signs. There was delay in tonsil healing.

It will be seen that there were four cases of unequivocal scarlet fever, one of diphtheria, and two in which scarlet fever was at first suspected but not confirmed. In these instances infection had doubtless already occurred before the operation. In one of them it was afterwards discovered that the patient's sister was also attacked at about the same time.

The occurrence of such a complication strongly suggests the expediency of allowing an interval of one or two weeks to elapse between the diagnosis and the removal of an acutely inflamed tonsil. Not that the operation itself under such conditions is necessarily associated with exceptional risk to the patient, but rather in consideration for others.

Since in most cases of adenoids and enlarged tonsils the submandibular and cervical lymphatic glands are prominent, it was not surprising that they showed further signs of activity by an increased thickening and tenderness, extending in three instances to acute suppuration.

The healing of the tonsil wounds was considerably delayed in three cases, while acute suppura-

tion of the middle ear—a by no means unusual complication when nasal douching played so conspicuous a part in the after-treatment—was present in one instance only.

While these clinical details may, perhaps, help to throw a little more light upon the pathology of the subject, it must be frankly admitted that they do not carry us much nearer a satisfactory explanation than is already embraced in the familiar term "surgical rash," and any interpretation must obviously be influenced by the particular aspect from which the *rôle* played by these lymphoid structures is viewed.

The view that this rash is solely due to bromides, salicylates, or other drugs may now justly be excluded, but the evidence strongly suggests that the lymphoid tissues of this region possess a somewhat high degree of vulnerability when disturbed, since operative treatment or any interference with the continuity of their surfaces seems to favour the entrance of bacteria or their toxins, which, in turn, give rise to a dermatitis, with or without signs of constitutional disturbance. (*a*)

Whether the invasion be due to (1) purely mechanical causes, to (2) interference with the tonsils' phagocytic duties, or (3) to inhibition of a probable alexine function, are points for consideration. It is, however, important to note that there is no suggestion of an epidemic character in the grouping of the cases, since very wide intervals of time elapsed between them. Further, there is no special reason for associating the rash with infection at the time of operation, since every reasonable precaution with regard to cleanliness of hands and instruments was employed.

That these lymphoid structures are specially prone to coincidental and sympathetic activity is well shown in the prominent part which they play in various infective fevers. This aspect has recently been emphasised by Dr. H. E. Biss (*b*) in a most suggestive article dealing with the interrelationship of tonsil inflammation, scarlet fever, and diphtheria.

Has this particular rash any relation to scarlet fever? Is it a "borderland" or modified type of scarlet fever? Unfortunately questions as to a possible immunity from scarlet fever or measles were not systematically noted. In four cases, however, there is record of the patients having suffered with scarlet fever and two from measles.

That the rash may be the result of septic absorption through the often large area of this operation wound is not at all unlikely, considering the unhygienic homes and surroundings of most of our out-patients; in fact, it is remarkable that septic complications are so few. Still the rash is not confined to such, for one occurred in our own wards, and one in private practice, where the operations and after-treatment were under the most favourable conditions.

The occurrence of so large a proportion of rash cases between the age of five and ten is doubtless due to that period being the one during which operations for adenoids and tonsils are most frequently performed.

In conclusion, it may be advanced that a rash may occur as a sequel to the removal of adenoids or tonsils; that, from the absence of signs of constitutional disturbance and from its atypical characters it may reasonably be assumed to be non-specific. But that assumption does not relieve the responsibility for taking precautions.

It may be further urged that since enlarged or inflamed tonsils may be the earliest evidence of a specific infection, their removal, unless otherwise urgent, should be postponed pending observation.

THE MODERN SURGERY OF THE PROSTATE. (*a*)

By SIR WILLIAM MITCHELL BANKS, M.D., F.R.C.S.,

Consulting Surgeon Liverpool Royal Infirmary, &c.

THE lecturer first described a typical case of acute prostatic retention with its generally disastrous termination after the treatment in vogue when he began practice, and eulogised the work of Sir Henry Thompson, which had completely revolutionised the whole conduct of urinary surgery. Passing over Bottini's treatment by the electric cautery, as one of which we have no practical experience in this country, he recalled the work of McGill, of Leeds, with which he was well acquainted. Had not death cut short the labours of this very admirable surgeon, he would almost certainly have still further advanced the surgery of the prostate. His method of attacking the gland from above by means of suprapubic cystotomy showed a fine combination of courage and originality. The mortality from hæmorrhage and sepsis was, however, severe and the operation did not gain ground. When Freyer made public his operation it was so novel in its character and so opposed in appearance to anatomical possibilities that many persons would not believe that it could be done, and he himself was one. But he ventured frankly to say that this would not have occurred if at the outset it had been clearly pointed out that there was no comparison between the normal anatomical prostate and the pathological adenomatous prostate. But the attempt made to deprive him of the credit due to him by saying that his operation was simply that of McGill was very paltry.

The writer saw McGill's specimens and patients some fourteen years ago, and it was plain that his operation was mere nibbling in the effort to get away as much as possible of the gland, and that by means of instruments. Freyer's operation is done with the avowed object of removing the whole gland bodily by enucleating it with the finger, even if the prostatic urethra had to go too.

He referred to the magnificent specimens exhibited that night by Mr. Freyer and to his mortality of 10 per cent., a low mortality considering what was done, and the age and the condition of the patients to whom it was done.

Allusion was made to the operation of Parker Sims, by which the gland was removed by the perineal route, an operation which doubtless promised a better drainage than by the suprapubic, but which, although apparently making great way in America, had so far not been extensively used in this country.

(*a*) Abstract of brief Paper introducing discussion on the subject at the Liverpool Medical Institution, January 21st, 1904.

Coming to the question of double castration, while admitting the direct effect of the removal of the testes in diminishing the prostate, he never could bring himself to do it, and he was glad to think that its own inherent defects and Freyer's operation would, ere long, render it a thing of the past.

He regretted very much that Mr. Reginald Harrison's excellent attempt to accomplish by the safe and easy operation of vasectomy any good that had been done by castration had not proved as successful as he could have wished. With regard to his own experience in this department of surgery, it all went to show that early treatment was the real line upon which efforts should be made. So soon as a man showed any symptoms of enlarged prostate, and so soon as his surgeon found that he did not completely empty his bladder, so soon ought that man to draw off his water at night with the biggest soft catheter he could pass.

A silly phrase—"entering upon catheter life"—had done a great deal of mischief by inducing many to believe that this was entering a kind of hell upon earth, the tortures of which were brought on by the use of the catheter. The second point was the prompt use of prostatotomy in certain cases. When a man having symptoms of a big prostate suddenly gets retention, and where it is clear that instruments of any kind can only be passed with difficulty and suffering, and that the retention of a catheter cannot be tolerated, the following proceeding has been promptly adopted by the writer with the greatest success in obtaining not only a relief from the immediate danger but a complete and permanent cure.

With the patient in the lithotomy position the membranous urethra is opened. The floor of the prostatic urethra is deeply incised, and the cut should go right up into the bladder so as to split any valve-like third lobe or a cervix-like protrusion. Next the prostatic urethra should be dilated to the utmost with the finger and the biggest possible glass tube inserted and worn at least for a month.

It may be said that every surgeon in an urgent case does a urethrotomy and drains the bladder; so he does, but he does not split the lower lobe of the prostate as described, nor does he forcibly dilate the prostatic urethra and keep it dilated afterwards.

A SOURCE OF INFECTION DURING OPERATION

HITHERTO NOT SUFFICIENTLY RECOGNISED. (a)

By MENDES DE LÉON, M.A., M.D.,
of Amsterdam.

MR. PRESIDENT and GENTLEMEN,—I must begin by apologising for having to speak in a language which is not my own, and therefore not as easily and as fluently as those you are accustomed to hear. In the second place I must apologise for calling your attention to a question that is not entirely, or at all events not specially, gynæcological. Surgery has, however, nowadays taken such an important place in therapeutics, and especially so in gynæcology, that the question of antisepsis and asepsis can never be entirely devoid of interest, though it may, as you say in England, seem like carrying coals to Newcastle for a Frenchman or Dutchman to come to the land of Lister and address there a Society which counts among its members so very many distinguished surgeons whose results speak for themselves.

For years past we have sterilised our hands, our instruments, the field of operation, and everything that is necessary for its performance; new methods of sterilisation and new apparatus are being introduced nearly every day. During the last five or six years no less than thirty papers have appeared dealing merely with the way we should sterilise our hands; so it would really seem as if nothing has been left unsaid or undone as far as this question is concerned. In fact, since Robert Koch's investigations in 1878 on the etiology of wound infections, we have become thoroughly convinced that such infection occurs only from contact, and we have sterilised everything that is likely to approach the wound.

In some few publications stress has been laid on the possibility of air infection, and it has seemed sometimes as if the whole theory of the great Lister might be thrown over and forgotten. The idea that the microbes of the air might play a more important part in wound infection, than most of us were inclined to think, occurred to me by mere chance in the following way: About a year ago, while speaking to a friend who was standing with his face lit up by rays of sunlight coming through a small hole in the window curtain, I noticed that of the thousands of little particles of dust, dancing in the sunlight, the majority, while this gentleman was speaking, travelled in a direction opposite to the sunrays, that is to say, from the mouth towards the window. At first I thought that the direction given to these little particles of dust was due to merely his speaking, but on approaching him and putting my hand near his mouth I felt it moist. I therefore concluded that the phenomenon was caused by little particles of saliva projected from his mouth in the act of speaking. We know that some people, when speaking, have the very disagreeable habit of spraying saliva about from their mouth, and sometimes we can even feel it on our faces and hands; but it is easily proved that this discharge of saliva is far more common than has been recognised, that perhaps everyone in speaking emits more or less. If we place a looking-glass at a distance of 25 to 30 centimetres from the mouth, after speaking a few words in its direction we can see that the whole surface of the glass, or a great part of it, is spread over with small drops of saliva.

Now, every surgeon is obliged to speak during an operation; and it is therefore evident that drops of saliva such as I refer to must find their way into the wound when we are operating, and the question arises whether this is dangerous to the patient, and likely to cause infection of the wound.

I felt sure that this was the case and decided to investigate the matter more closely. Whilst occupied with my experiments I consulted the literature, and found the old saying true that there is nothing new under the sun. This question had been investigated by others before me, though I was not aware of it, perhaps because what had been written and said about it was in hygienic and bacteriological works, or in meetings of societies on those lines, rather than in connection with surgery or gynæcology. Flügge was the first to point out the danger of small drops of saliva sprayed into the air, which occurred to him whilst he was investigating the question of the ventilation of sick and invalid rooms, and he pointed out the risk of infection from tuberculosis and other kinds of disease in this way. Huebener, who was at that time assistant to Micholitsch, hearing of the researches of Flügge, thought the same danger might apply to operating, and by personal experiments demonstrated that in speaking many drops of saliva were projected into the air, and might easily pass into the wound during operation. Having rinsed his mouth with a culture of the *Bacillus prodigiosus*, he spoke on to agar plates prepared for the experiment, and in twenty-four to thirty-six hours a multitude of red colonies were distinctly visible upon

(a) An Address delivered before the British Gynæcological Society the Annual Meeting on January 14th, 1904.

the plates. This could not be due to anything else than the drops of saliva which had left his mouth in speaking. These experiments and researches, though important, did not seem to me to be conclusive as to the possibility of infection, because saliva might reach the wound without causing infection. I therefore wished to determine what forms of microbes leave the mouth in the saliva, and if possible what number of them. That the human mouth is a great focus of infection has been abundantly proved by hygienists, and very definitely also by members of odontological societies and dentists in England and elsewhere. Miller, one of the foremost dentists in Berlin, found twenty-two different sorts of germs or microbes in the saliva, and he and Goadby, of London, and others have traced all kinds of local diseases, even alveolar abscesses, osteitis, osteomyelitis, periostitis, fistula, and septic troubles in the lungs and digestive tract to microbes which occur in the saliva, or at any rate in the mouth. But what I wished to investigate especially was not that, but how much of the saliva leaves the mouth in speaking. My experiments were carried out in the following way. I had some agar plates prepared in Huebener's way, but instead of rinsing my mouth with the *Bacillus prodigiosus* as he had done—and I was experimenting myself before I knew of his work—I spoke on to the plate in the ordinary way. The difficulty was to shut out the microbes of the air, numbers of which we know are suspended in the air in any room, and especially in that of a laboratory. To exclude these microbes I had a box made with an opening about as large as the mouth on its upper side, and a sliding drawer at its base; having carefully sterilised the apparatus I opened this sliding drawer, put one of my agar plates upon it, and shut it immediately, so that I could be sure there were no aerial microbes in the box. I had previously got my assistant to write down all the words I had spoken at an operation these words I repeated into the box through the opening in the direction of the plate, and of these plates I now show you one. The very small colonies which you can see on the plate are streptococci, every one of them; the larger whitish ones are diplococci, and the yellow ones staphylococci. Now these plates prove that when we speak microbes are emitted from our mouths, and if we are operating those microbes will be projected into the wound. In fact, in speaking while operating we emit multitudes of most dangerous and infectious germs, which are a source of real danger. I have traced four sorts of these germs in every one of several hundred experiments I performed, that is to say, streptococci, staphylococci, diplococci, and an aerial microbe not of so much danger in wounds as the others.

Now, gentlemen, I wished to determine not only the sorts of germs emitted, but also, though mathematical accuracy was out of the question, to find out as nearly as possible how many of these germs were projected into the field of operation. I show you another of these plates on which instead of agar I spread out about half a dozen of the usual cover slips, and spoke into the box against them in the same way. On those cover slips I found a number of small drops of saliva, which I stained in the usual way and examined. Now, on a surface of about 2,000 micro-millimetres I found 140 germs of the forms already mentioned, and easily countable. One little drop of saliva measured, as near as possible, on the surface, 62,500 micro-millimetres. This multiplied by 140 and divided by 2,000 gives 4,375 microbes for one drop of saliva. In speaking 200 words you will certainly emit at least sixty drops of saliva, and I am sure, gentlemen, each of you will speak at least 200 words even in an operation lasting only a quarter of an hour. So if we multiply this number 4,375 by 60, we may assume that nearly a quarter of a million dangerous microbes fall into the wound. To meet the possible objection that these streptococci, diplococci, and staphylococci may be innocent, because we know that sometimes streptococci are not virulent at all, I thought it well to go a little further, and study the virulence of the streptococci and other microbes from my own mouth. I therefore had them cultured, and I inoculated about sixty animals —that is to say, 41 guinea-pigs, 15 white mice, and 5 rabbits. Of these, 8 guinea-pigs and 10 white mice died. The inoculations were made into the peritoneum and subcutaneously, and the sections after death showed that the animals died of peritonitis; the microbes were found in the liquid exudation from the peritoneum as well as in the liver and heart. I am, therefore, absolutely sure that the deaths were due to the inoculation. Two of the rabbits died also, but as their death occurred two months after the inoculation I did not think it right to attribute their death to that cause. From these animals I obtained pure cultures of the microbes upon gelatine, milk, potato, and blood-agar, and there was not the slightest doubt that they were the staphylococci and streptococci, the germs which cause suppuration and inflammation.

It now seemed to me proved that we are continually risking infection of wounds when we operate, and I felt it of the greatest importance to find out how we might prevent such infection. When I consulted the literature of the subject I found that in this direction nothing adequate had been attained. The most reasonable advice that had been given was, to abstain from speaking at all. But, as I have already said, this is practically impossible. Every surgeon must admit that whenever he operates he not only speaks, but speaks a good deal; some surgeons speak all the time, and often with the face very near the field of operation. It is true that sometimes the mouth is averted, but very often they speak directly into the wound. Moreover, the more difficult the operation, the more excited and agitated the operator becomes, and the more and the louder he talks, while if he have a stupid assistant or stupid nurses, or both, he cannot help talking harder and more excitedly than when everything goes smoothly and calmly. And, of course, the louder and the more rapid the talking, the greater the number of microbes which are emitted into the wound, or, at any rate, into the air round the wound. I do not, however, wish to submit to you merely my own experience. During the last six or seven operations which I have done I asked one of my assistants to note exactly how many words I had spoken and what I had said. I also asked some of my surgical friends to do the same, and six of them were kind enough to comply, and answered my questions. The first of these spoke 85 words, another 248, another 200, another 226, and another 144 words, while number six spoke 246. And we must remember, in the first place, that these numbers are minima; what the assistants said was not noted, and every assistant has occasionally to answer a question or instruction addressed to him. In the second place, many words must have been indistinctly heard or forgotten and, therefore, not noted down. In the third place, I have no doubt that some of these gentlemen, under the conditions I imposed, spoke less than they usually do. One of them was honest enough to write to me and say that it was impossible for him to continue operating in this way; being obliged to abstain from speaking was such a strain that it made him nervous; and that as a rule he spoke four times as much as when he was conducting the experiment I asked him. So the advice not to speak during an operation is all very well, but practically it would be quite impossible to carry it out. A second method suggested to prevent the infection of wounds from talking is by rinsing and so sterilising the mouth with an antiseptic. But we know that to sterilise the mouth properly we should have to use a solution of sublimate, and the buccal mucous membrane is too delicate to allow this. Many experiments indeed have been made in this direction, especially by the odontological branch of the profession, and I tried several of those which they recommend. There is a prescription by Miller of a solution containing benzoic acid and saccharine which I tried, but the only effect it had was to produce much more saliva in my mouth than under ordinary circumstances. I also experimented with my plates when using this substance, and found on them the same germs as before. The more liquid part of the saliva contains multitudes of streptococci, which are the worst of the lot. I also tried odol and other well-known washes, but none of them had

any effect at all in diminishing the number of organisms which were emitted in speaking. I therefore concluded that the only way of preventing this danger was to adopt mechanical means; that is to say, to try to prevent in a mechanical way any saliva leaving the mouth, and carrying microbes into contact with the wound. Huebener and others have employed masks with this object, and perhaps some gentlemen here present have also done so. The masks are made some of single, and others of double gauze, and I experimented with both kinds in the same way I have already described. Speaking in front of the plates with a single gauze mask on resulted in 75 colonies of microbes on the plate, among which there were 39 of streptococci; with double gauze there were 21 colonies. Of course with the double gauze masks the number of microbes which found their way outside was much less, but in both cases there were far too many. Finally, I concluded that the best way to prevent these microbes doing any harm by escaping into the air was to shut the mouth off with cotton wool, because we know that cotton wool is the most certain way of excluding microbes. The difficulty was to find means of keeping the cotton wool before the mouth while operating without causing inconvenience, but I devised this very simple little apparatus, which seems to me to answer the purpose in a very efficient way. It is a respirator, and between double metal plates, each of which is perforated with small holes, there is room for a small quantity of wadding, which is quite sufficient for the purpose. After it has been inspected I will put it on, and you will find that it does not interfere with speech, that can be easily heard, though it does prevent the exit of dangerous microbes from the mouth. I show you, moreover, one of the agar plates which has been spoken upon through this mouth-piece, and you can easily prove for yourselves that not a single colony of microbes has been developed upon it. I repeated this experiment several times, to make sure, but always with the same result. One or two colonies sometimes could be seen on the plate, but I satisfied myself that they could only have come there through air infection, for there must have been a few moments during which the slide was exposed to the air before the drawer could be pushed back again.

The conclusion which I desire to bring before you is, that where we take so much trouble in sterilising our hands, our instruments, and the whole area of operation as well as the room in which it is done, and everything which comes near the patient, we ought not to neglect this simple precaution against the risk of which I have been speaking, for I hope I have been able to convince you that it is a real danger, and it may be as great a source of infection as those which we habitually guard against.

I have to thank you, Mr. President, for allowing me the opportunity of explaining this little matter at which I have been working, and you, gentlemen, for having so kindly and attentively listened to me. I may mention that I have placed under the microscopes on the table slides containing micrococci and diplococci which I cultivated from the inoculated guinea-pigs, as well as others directly sown by speaking.

Clinical Records.

ANÆSTHESIA DURING OPERATION FOR TWO CASES OF ACUTE INTESTINAL OBSTRUCTION.—A LESSON.

By VICTOR G. L. FIELDEN, M.B.,

Senior Anæsthetist to the Royal Victoria Hospital, Belfast; Anæsthetist to the Ulster Hospital for Children and Women; and to the Belfast Ophthalmic Hospital.

THE following notes may prove instructive to anæsthetists:—

CASE I.—On April 28th, 1903, I was asked to give chloroform to a gentleman, æt. 63, who was suffering from acute intestinal obstruction. He had been brought to a private hospital that same morning, and had vomited once after admission, but the nurse assured me it was not fæcal. His general health was good. I administered chloroform, and but for a slight amount of struggling during the narcotic stage, all went well. Colotomy in the right inguinal region was being performed, and towards the close of the operation, after about twenty to thirty minutes' inhalation, a quantity of fæcal fluid was regurgitated. This occurred without any effort during absolutely quiet breathing and well contracted pupils. The face had been all through the administration turned towards the right side, but the amount of regurgitated fluid was more than enough to flow from the angle of the mouth, and a quantity of it was immediately drawn into the trachea. The face immediately turned blue, the inhalation was stopped, the head lowered, and means of resuscitation persevered with, during which the operation was completed. The pupil remained contracted until after artificial respiration was begun. Pulse and respiration failed absolutely about three-quarters of an hour after the regurgitation of the fæcal fluid, the blueness of the face having deepened as each inspiration carried the fluid into the smaller bronchioles.

This unhappy case naturally set me thinking, with a view of avoiding a repetition in any future case. *Vomiting* is frequent enough during or after the administration of an anæsthetic, but in these cases the epiglottis completely closes the respiratory tract, and the vomited matter cannot enter unless it is allowed to remain in the mouth or pharynx until the glottis opens during the next deep inspiration. *Regurgitation*, on the other hand, as happened in my case, is the passage of fluid from a more or less filled stomach without effort, and whilst the patient is breathing normally, and whilst the glottis is open. We have no means of knowing the amount of the contents of the stomach, for even if the patient has "vomited" just prior to the operation, he may not have emptied his stomach; consequently there is an unknown quantity there. Again, the necessary manipulation of the intestine increases peristalsis. (I have frequently seen a surgeon demonstrate increased peristalsis by lightly tapping with an instrument a coil of bowel which he had withdrawn through an abdominal wound.) If, then, the surgeon's handling of the bowel increases the peristaltic, or in the case of obstruction, the so-called anti-peristaltic, action more or less of the intestinal contents are returned to the stomach and the unknown quantity is increased thereby until possibly it contains such an amount that it expels more or less by the only possible route—the œsophagus.

With this reasoning I decided that it should be a routine practice for anæsthetists to wash out the stomach of intestinal obstruction cases, no matter whether the patient had recently vomited or not. Two days ago I had an opportunity of carrying out my views with the best possible results. Notes of this case I briefly record—

CASE II.—On January 10th, 1904, I was called to the Royal Victoria Hospital to anæsthetise a man, æt. 35, upon whom laparotomy was to be performed for acute intestinal obstruction. He had vomited fæcal fluid several times during the morning, but I, immediately on my arrival, set about washing out his stomach. It contained a good quantity of fæcal fluid which was syphoned off and the viscus washed out with two or three quarts of water. Half an hour or more elapsed before he was put upon the table, and although he had not vomited in the meantime, I deemed it advisable to pass the stomach-tube again, although he had been given nothing in the meantime. I was somewhat surprised to find nearly half a pint of fæcal fluid syphon over. I washed him out with a quart of water, and then proceeded to give chloroform. The operation for the relief of the obstruction was followed by appendicectomy, the duration of the administration being seventy-two minutes. Not once was there the slightest trouble, and he did not vomit again till sixteen hours later, when he brought up a little which the nurse informed me was not fæcal.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

CLINICAL EVENING HELD FRIDAY, JANUARY 22ND, 1904.

DR. FREDERICK TAYLOR, President, in the Chair.

DR. F. PARKES WEBER showed two cases of

DIFFUSE LIPOMATOSIS.

The first case was that of a single woman, æt. 34, who presented typical diffuse lipomata below the lower jaw, on the upper arms, and on each side of the front of the thorax. She had always enjoyed good health, and was not excessively fat. There was no evidence of any disease of the thoracic or abdominal viscera or of the nervous system. The thyroid gland could be felt and was apparently not abnormally small. The condition had been noticed for about two years, and was unassociated with pain. She had been treated by thyroid tabloids. The second case was that of a man, æt. 52, who was formerly a carman. The lipomatous masses, which affected the neck, arms, and pubic region, first appeared in 1868, following an injury. There had been slight general wasting, in connection with which it was suggested that there might be some cirrhotic change in the liver. The development of ascites had sometimes been observed in cases of diffuse lipoma with general wasting.

DR. A. E. GARROD exhibited a boy, æt. 10, with a

TUMOUR OF THE LIVER.

When first seen in August, 1903, he was said to have been ailing for a year, and to have had pain and swelling in the left side. The liver was then much enlarged, and reached below the umbilicus. It was firm, and not tender. One large and several smaller swellings were felt on the surface of the right lobe near the costal margin, which were hard and yielded to fluctuation. The lymphatic glands in the neck were enlarged. There was double dacryocystitis with conjunctivitis, and interstitial keratitis more marked in the left eye. There were no changes in the fundi. The teeth were badly formed, but were not characteristic of congenital syphilis. He had taken iodide of potassium almost continuously. It was thought that the tumour was probably of a gummatous nature, but the diagnosis of hydatid had also been advanced. No blood changes had been observed.

DR. G. A. SUTHERLAND thought that the hardness of the mass, as well as the presence of old keratitis, strongly suggested gummata. He inquired if mercury had been employed at all in the treatment.

THE PRESIDENT asked if there had been pyrexia at any time.

DR. GARROD replied that the boy had taken a small quantity of mercury some months previously, but that he intended to put him upon a course of the drug together with the iodide. There had never been any fever.

MR. W. H. B. BROOK (Lincoln) showed a case of

TOTAL PARAPLEGIA DUE TO CARIES OF THE MID-DORSAL VERTEBRÆ,

for which the operation of costo-transversectomy had been performed with complete recovery. The patient was a youth, æt. 18, the notes of whose case had been read before the Society in March, 1903. The fact that the patient had undertaken a railway journey of over one hundred miles was, in itself, sufficient evidence of the completeness of his recovery.

MR. LAWRIE H. MCGAVIN considered that the thanks of the Society were due to Mr. Brook for bringing the case before its notice, and congratulated him upon such a successful issue.

MR. J. R. LUNN showed (1) a case of chronic periostitis (syphilitic) in a man, æt. 28, affecting the lower ends of both femora. A skiagram was shown to illustrate the condition. (2) A case of ununited fracture of radius and ulna in a man, æt. 74, which had existed for a period of thirty-eight years. The accident was a compound one, and when first seen he was advised amputation, but he refused. (3) A boy, æt. 13, with symmetrical swellings on the lower jaw. He was also the subject of congenital syphilis.

MR. HAROLD S. BARWELL thought that the condition was one of dentigerous cysts.

MR. WALTER G. SPENCER exhibited a boy, æt. 10, with bilateral enlargement of the testicles. Both testes were swollen to about adult size, and firmly elastic, but not tender; the right was rigid and enlarged, the left less so. A sinus existed over the front of each testis which had ceased to discharge pus, and appeared to be healing. The patient did not present any further signs of past or present disease. An indefinite family history suggested both tubercle and syphilis. He had been under observation for three weeks, and was treated with mercury internally and locally, with a little iodide.

MR. ANTHONY A. BOWLBY thought that the fact of there having been previous suppuration was in favour of tubercle.

MR. RAYMOND JOHNSON said that the presence of sinuses in front of the testes suggested that the disease began in the body of the organ, which was rather more common in syphilis, but in view of the conversion of the whole gland into a hard mass, he agreed that the case was one of tubercle.

MR. PERCY PATON, in the absence of Mr. Spencer, said that he believed that the latter was inclined towards a diagnosis of tubercle.

DR. FREDERICK E. BATTEN showed a little girl, æt. 5, the subject of complete ophthalmoplegia externa with blindness of acute onset. Thirteen weeks before admission to hospital the child had whooping-cough, from which she recovered, and was well in about six weeks. Two weeks before admission the child had headache, pain in the abdomen and across the shoulders; there was no vomiting. One week before admission the mother noticed that the child could not see, and the child asked her mother to bring a candle because it was dark. At the same time it was noticed that the pupils were very large, and she could not move the eyeballs. There was no loss of consciousness, no convulsions. On admission, the child was well nourished, intelligent, and suffered no pain. There was no ptosis, but complete ophthalmoplegia, with a slight divergent strabismus. The pupils were widely dilated, and did not react to light. There was complete blindness. There was slight optic neuritis, more marked in the right eye than the left. There was no weakness of the muscles of the face, tongue, palate, or limbs. The child walked with the unsteadiness of a blind person, and there was a very slight inco-ordination of the movement of the right arm. All the deep reflexes were abolished. The superficial reflexes were present. The plantar reflex gave a variable response, sometimes definitely flexor, at other times a typical skin extensor response was elicited. Within a week after admission the movement of the eyes had greatly improved, but the pupils remained dilated, and there was no return of vision. Fourteen days after admission the movements of the eyes had become normal, the pupils were no longer so dilated, and the optic neuritis was much less. There was no return of vision, and the knee-jerks still remained absent. While in the hospital there was no rise of temperature, no headache, no vomiting, and the child was generally bright and intelligent. It was suggested that the case was one of polio-encephalitis inferior affecting the oculo-motor nuclei and the lower visual centres.

MR. LAWRIE H. MCGAVIN showed a married woman with complete absence of the phalanges of the left hand. The patient, who was the sole member of her family affected by any bodily deformity, was healthy in other respects. The skiagram showed that the whole of the phalanges had been suppressed, the metacarpal bones also revealing deformities. The case was a good example of the value of even a portion of

the thumb, as the patient had brought up a family of five children and had made all their clothes herself!

Mr. RAYMOND JOHNSON showed a man, æt. 28, with a translucent cystic swelling of root of nose. The condition was first noticed about three years ago. No cause could be assigned, and it had slowly increased without pain. The cyst gave a well-marked sense of fluctuation, and its tension appeared to be quite constant. It was possible that it was of parasitic origin.

The PRESIDENT asked what form of parasitic disease was suggested.

Mr. HORROCKS OPENSHAW considered that the condition was one of meningocele.

Mr. DOUGLAS DREW thought that an exploratory puncture of the cyst might be undertaken with aseptic precautions in order to confirm the diagnosis.

Dr. ARTHUR E. T. LONGHURST inquired what form of treatment would be adopted.

Mr. RAYMOND JOHNSON replied that the extreme translucency of the swelling rather pointed to the presence of a dermoid, and that it would be better to incise the cyst, and, if possible, remove it.

Mr. R. JOHNSON also showed a man, æt. 47, the subject of multiple aneurysm, in whom an aneurysm of the right brachial artery was removed by operation in July, 1902. Eighteen months afterwards, the other aneurysms situated on the left brachial artery, at the bend of the elbow, and on the left popliteal artery, had remained in precisely the same condition.

Dr. WILFRED HARRIS exhibited two cases of post-diphtheritic bulbar paralysis. Both the patients were young women, æt. 25 and 29 respectively. The electrical reactions showed considerable diminution to faradism in the paralysed muscles.

Mr. CHARLES R. KEYSER showed (1) a case of congenital elevation of the shoulder in a girl, æt. 9. There was no history of injury or paralysis, nor was any other member of the family affected by any bodily deformity. There was no muscular paresis, and the X-rays did not show anything abnormal. (2) A case of congenital absence of the fibulæ in a male child, æt. 2½. There was bilateral talipes valgus and only four toes on each foot.

Mr. C. GORDON WATSON exhibited two cases of osteitis deformans in a man, æt. 73, and a woman, æt. 53, respectively. In the first case, the left femur and the skull were principally affected, while in the second, the left tibia was chiefly involved.

Mr. WILLIAM H. BATTLE showed a case of fracture-dislocation of the upper cervical spine in an adult without symptoms. The patient was a man, æt. 56, who had fallen down a staircase a month before admission to hospital. A skiagraph showed a fracture of the axis with displacement forwards of the atlas and axis from the spine.

Mr. EDRED M. CORNER showed (1) a case of fracture of both pedicles of the atlas; and (2) a case of fracture of the body of the fifth cervical vertebra. In both cases a considerable interval elapsed before the patients came to the hospital, and in neither were there any paralytic or sensory symptoms. Mr. Corner considered that Mr. Battle's case and his first one might be termed reasonably frequent fractures, and that if skiagraphs of the spine were taken in all cases of severely sprained necks, a large proportion of them would, in all probability, reveal the presence of a fracture.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

MEETING HELD FRIDAY, JANUARY 15TH, 1904.

The President, DR. EARL, in the Chair.

HORSESHOE KIDNEYS.

THE PRESIDENT and Dr. TRAVERS SMITH showed tuberculous suprarenal bodies and a horse-shoe kidney, from a case of Addison's disease.

The PRESIDENT also exhibited a second horse-shoe kidney.

Prof. MCWEENEY said out of many hundreds of autopsies which he had made he found but one horse-shoe kidney, which was situated much lower down than usual; in fact, the connecting isthmus lay over the sacro-iliac synchondrosis.

DEFORMITY OF LIVER.

The PRESIDENT showed a liver with deformity, probably produced by tight lacing. A portion of the right lobe close to the right side of the gall-bladder was turned right over so as to come in contact with the upper surface of the liver.

PARAFFIN METHOD OF EMBEDDING.

Prof. MCWEENEY showed an adaptation of the paraffin method of embedding tissues suitable for class purposes. The sections were cut in chains, floated off in convenient lengths as usual, and taken up on thin sheets of mica, to which they were caused to adhere by capillary attraction. The mica sheets were cut up, and the divisions, each bearing a section, given out to the class. After removal of the paraffin as usual, the students stained and mounted the sections which adhered throughout to the mica, and were mounted in balsam along with it. Exhibitor owed his acquaintance with this useful method to his friend Professor Coffey, who had acquired it in Held's laboratory.

RINGWORM.

Prof. MCWEENEY showed sections of ringworm-hairs prepared by the paraffin method, and adapted by the mica method for distribution to a class. They showed the characters of the several forms of ringworm, especially the microsporon, and their relation to the hair shaft and root sheath. The microsporon spores in the Irish cases he had studied gave notably larger measurements than those usually recorded—4 to 6 mikra, instead of 2 to 3 mikra as generally given. He also showed young microsporon plants grown from single spores on "French proof agar," as well as in epidermic scales. The acladium form of branching and ectospore formation were well seen in the hanging-drop cultures. For staining, he had found Heidenhain's iron-hæmatoxylene after formol-vapour fixation most useful. The nuclei of the young mycelium were well seen under high powers. He had it in contemplation to undertake a comparative study of Irish skin-fungi by the methods he now outlined—*viz.*, isolation of individual spores and culture on French proof agar.

ENDOMETRITIS.

Dr. NEVILLE exhibited photographs made by Dr. Wigham of various varieties of endometritis.

CANCER OF OVARY.

Dr. NEVILLE showed macroscopic and microscopic sections of cancer of the ovary.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 14TH, 1904.

DR. HEYWOOD SMITH, President, in the Chair.

THIS being the Annual Meeting of the Society, in the unavoidable absence of the treasurer, Dr. William Travers, his report and balance-sheet for the year 1903 were read by the senior secretary, Dr. Swanton, and on the motion of Mr. Bowreman Jessett, seconded by Dr. George Elder, were unanimously adopted, with an expression of regret at his resignation, earnest hope for his complete recovery, and the thanks of the Society to him for his past services. The report of the Editor of the *Journal* of the Society having been read by Dr. J. J. Macan, it was adopted on the motion of Dr. Macnaughton-Jones, seconded by Dr. Macpherson Lawrie, and a vote of thanks to Dr. Macan in appreciation of the efficiency of his work was unanimously passed, together with a vote of thanks to Drs. Purcell and Bennett for their services as auditors. The officers of the Society for the current year were then elected, a complete list of which appeared in our last issue.

The PRESIDENT exhibited the modification of

BOSSI'S INSTRUMENT FOR DILATING THE CERVIX UTERI,

devised by Frommer, and demonstrated the ease with which any one or more of the eight blades could be removed, so that it was possible instead of commencing the dilatation with the finger to begin the process with three blades only and complete it with the eight. The action was controlled by a screw, and the exact amount of expansion was indicated on a dial on the handle. The risk of lacerating the cervix was materially diminished by having eight blades instead of four.

Dr. MENDES DE LÉON, of Amsterdam, then gave an address on

A SOURCE OF INFECTION DURING OPERATIONS HITHERTO NOT SUFFICIENTLY RECOGNISED,

which will be found on page 82.

After delivery of the address, the PRESIDENT said he felt sure the Fellows would wish to thank Dr. Mendes de Léon for his very valuable and interesting paper. The effect of habit and temperament in operators was very remarkable. Some went on talking nearly the whole time; others, and he thought the best operators, conducted their work without speaking at all. He thought the upshot of the author's experiments was that they should never speak at the operating table except when it was absolutely necessary. Dr. Macnaughton-Jones had recently read a paper which would be interesting to the author of the one they had just heard, as it was upon a kindred subject—the care of the mouth and teeth, a much neglected source of infection, prior to operations upon the pelvic viscera.

Dr. MACNAUGHTON-JONES, in expressing his appreciation of the interesting paper of Dr. Mendes de Léon, and the experiments with which he had illustrated it, said that he doubted if we could ever arrive at a perfectly ideal asepsis. There were so many possible sources of the admission of infective germs in the surroundings of the operation — the patient, the surgeon, the assistants, the nurses, the appliances, and the operative tract itself, before, during, and after an operation—that all we could at the best hope for was to reduce to the lowest minimum the elements of risk which must always be present, no matter what our precautions. It was this striving for perfection that afforded the best security for our patient, and no effort such as that advocated by Dr. Mendes de Léon should be ridiculed or treated lightly. Abroad in some *klíniks* linen caps were worn, and also sacs to cover the beard. As to silence, speaking for himself, nothing irritated him more than unnecessary talk during an operation, but he supposed that this tendency varied with the nationality of the operator. The great *desideratum* was silence during an operation, and only such speech as was indispensable. The demonstration which they had seen left no room for argument as to the practical consequences which resulted from speaking over the wound, but fortunately they did not seem to result in any very serious effects on the patient, seeing the immunity of our graver operative procedures. Still, if we only saved one patient in a thousand on whom we operated from any evil consequences of salivary infection, it was our duty to take every precaution to prevent that risk. He could not say how the mouth-mask shown could be worn during a prolonged operation without inconvenience to the operator, but he would himself try it in order to ascertain this.

Modification of Bossi's Instrument for Dilating the Cervix Uteri.

Dr. HERBERT SNOW had great pleasure in seconding a vote of thanks to Dr. Mendes de Léon for his most interesting account of the experiments he had carried out with such care and perseverance. All progress towards asepsis was merely relative, and whatever the danger of the emission of small particles of saliva might be, the breath passing through the nasal cavities and mouth must be extensively loaded with microbes, and he did not see how infection from that source could be possibly excluded. Drops of perspiration were another danger. As the experiments of Lockwood, among others, had shown, absolute sterilisation could not be secured. Whatever was done, some microbes would be implanted on the wound. If, however, the tissues were in anything like a healthy state, and if the number of pathogenic germs coming in contact with the wound were relatively small, there would not be any serious trouble. It would be interesting to know whether, before adopting the precautions described, Dr. de Léon had experienced disasters from undetected causes, which had not occurred since those precautions had been taken.

Dr. MACPHERSON LAWRIE expressed his sense of the great interest of the results arrived at by Dr. Mendes de Léon, but concurred with Dr. Snow in thinking that the breath of the operator might also be a fertile source of infection, and thought that the nostrils should be guarded as well as the mouth if it were desirable to cover the latter.

Dr. BEDFORD FENWICK said that the paper they had heard was of great practical as well as theoretical value, though the author had confined himself to the effects of speech. Many years ago his (Dr. Fenwick's) father made some original researches upon the effect of the saliva in health and disease, which at the time attracted attention, and in that work he had been privileged to assist. They had found that in all healthy people the saliva contained a large amount of sulphocyanide of potassium, and was therefore powerfully antiseptic. He could not therefore agree with Dr. de Léon in attributing more importance to the saliva than to the breath as a vehicle of micro-organisms, but thought, with Dr. Macpherson Lawrie, that as a source of infection the nose was as important as the mouth.

Dr. W. J. SMYLY having made a few remarks of appreciation,

Dr. MENDES DE LÉON, in reply, said that in regard to the amount of talking during operation, Dutchmen had not the same temperament as Irishmen, French, or Italians, and were generally supposed to take things very quietly; yet even men who said, "Well, my friend, I will do what you ask me, but it will be of no use, because I do not talk at all during operations," nevertheless sent him protocols of 200 to 300 words spoken over the wound. Though 300 words might seem a very large number, they might easily be said during an operation that did not take more than fifteen minutes. As a characteristic incident he might tell them that one of the best surgeons in Amsterdam, who habitually took extraordinary precautions against sepsis, noticing that an etherised patient seemed to be about to vomit, cried out with great energy, "Look out, she is going to vomit, and if you are not careful she will spit into the wound"—the very thing that he was, without knowing it, doing himself. Absolute asepsis was not, perhaps, obtainable, but every possible precaution should be taken, especially when so easy as the one he had suggested. Before he brought his mask before the profession, he had used it for several weeks during many operations, some of them lasting from an hour to an hour and a half, and he could assure Dr. Macnaughton-Jones that it did not cause the slightest discomfort. The instrument was very easily adjusted, and did not interfere with audible speech as he would

now show them (demonstration). In regard to the danger of germs being disseminated into the air from the nostrils, as insisted on by Dr. Lawrie and others, he did not deny the possibility, but was not convinced of the danger; the pathogenic germs he had demonstrated in the saliva had not been found in the healthy nose, though streptococci had no doubt in ozæna and similar inflammations been found there. He was absolutely convinced that the microbes emitted with the voice were conveyed by the saliva, and not merely by the breath, as suggested by Dr. Fenwick, for, in spite of repeated trials, he had never obtained any colonies upon his agar plates simply by breathing upon them. He had not been disappointed at this, as he knew that it was the saliva that caused peritonitis in the inoculated animals. Pathogenic germs might possibly be emitted from diseased lungs, but his experiments proved that they had been conveyed by the saliva on to the agar plates, upon which they had caused definite colonies. If every streptococcus or staphylococcus that fell into a wound caused infection, the effect of a quarter of a million of such would be terrible to contemplate; but, fortunately, this was not the case, and surgeons now had very good results, especially in gynæcology. We should, however, aim at the lowest possible mortality, and as the mysterious deaths that occasionsally occurred in the practice of even the most distinguished operators might be due to some such cause as he had pointed out, the admission of such a possibility and steps to guard against it could only be beneficial.

A cordial vote of thanks to Dr. Mendes de Léon having been carried by acclamation,

The PRESIDENT, Dr. HEYWOOD SMITH, then delivered his

VALEDICTORY ADDRESS,

reviewing the work done by the Society during his year of office. He first referred to the many interesting specimens shown, and cases narrated, and instruments exhibited. Of the many valuable papers read before the Society, of which by no means the least interesting was that brought before the Society that night by Dr. Mendes de Léon, might be mentioned the one by Dr. Macnaughton-Jones on "The Importance of Attention to the Condition of the Mouth and Teeth at Operations on the Pelvic Viscera"; on "Intestinal Obstruction After an Operation for Ectopic Gestation," by Mr. Jessett. Dr. Routh read a paper on "Some Directions and Avenues Through which Cancer may Possibly be More Successfully Treated and Perhaps Cured." Dr. Mansell Moullin read a paper on "Hæmatocolpos and Hæmatometra." Professor Taylor (the learned President-Elect) gave a valuable paper on "Lacerations of the Cervix and their Consequences." Dr. Bedford Fenwick opened an interesting discussion on "The Treatment of Stenosis by Incision"; and Dr. Mendes de Léon has given to-night a most instructive paper on "A Hitherto not Sufficiently Recognised Source of Infection During Operations." [All of these papers have appeared in the columns of THE MEDICAL PRESS AND CIRCULAR.] He next referred to the *Journal* of the Society, so ably conducted by its Editor, Dr. Macan, which contained, besides an accurate report of the Transactions, many very valuable original communications and the Summary of Gynæcology, including obstetrics, exhibiting a most painstaking and laborious effort, and keeping the gynæcologist fully up to date with the progress of the speciality all over the world. Dr. Heywood Smith next touched on the altered attitude of the Society towards the admission of medical women to the Fellowship, and on the establishment of an examination for gynæcological and maternity nurses. With regard to the former, he remarked that the Articles of Association and the by-laws of the Society were originally drawn up with the distinct view of the admission of medical women as well as medical men to the Fellowship, but a small minority of Fellows, although they joined the Society, yet were opposed to that idea, and, making their influence felt, frustrated in that direction the principles of the Society. Several important meetings on the subject, however, had been held, and he gave credit where it is due by stating that several members of the opposing minority, when they saw the manifest feeling of the Society on the subject, withdrew their opposition, and aided the Society in so altering their rules as to make the election to the Fellowship simpler, while at the same time safeguarding its interests with regard to the eligibility of any particular candidate. The establishment of a periodical examination for nurses, gynæcological and maternity, was, he remarked, fully explained in his Inaugural Address a year ago. It would suffice now to state that such examinations have been carried out by their Board of Examiners quarterly; that the examinations have consisted of written papers, the questions for which have been published from time to time in the *Journal*, and a *vivâ voce* examination, in which the examiners had been aided, as to practical work, by several matrons of hospitals, who willingly gave their help in this matter. Examiners have been well pleased with the high standard of the knowledge of their profession shown by the majority of the candidates so far as to work done during the past year. But he wished to draw attention to the cases, five in number, of sclerosis of the ovary that have been brought forward as indicating a field for further investigation and research. And, first of all, he thought the ground should be cleared as to the etiology of the disease, whether it is a "cirrhosis" or "sclerosis," and then proceed to map out the leading symptoms with the view to a correct diagnosis, and thence to the prognosis and treatment. His own view was that they represent two separate conditions; the specimens brought before the Society during the year tend to confirm this position. In *cirrhosis* we find the interstitial stroma first of all the seat of an inflammatory process and afterwards so contracting as to render the envelope convoluted, so that it presents an appearance not unlike the convolutions of the brain, whereas in *sclerosis* it is the envelope that is the chief seat of the abnormal thickening and induration, leading (as also in the case of cirrhosis) to contraction of the organ and to consequent dysmenorrhœa. Dr. Heywood Smith passed in review the deaths of Fellows during his year of office, and concluded his address by congratulating the Society on having elected as his successor so distinguished a Fellow as Dr. John William Taylor, M.Sc., Professor of Gynæcology in the University of Birmingham, and Surgeon to the Birmingham and Midland Hospital for Women. Professor Taylor, he added, was renowned not more for his operative skill than for his accuracy of diagnosis, the thoroughness of his research, and the value of his published works; and he was convinced that the Society, in thus electing him President for the ensuing year, had taken a step that could but result in the furtherance of the objects for which it was founded.

Professor JOHN W. TAYLOR, the President-Elect, said that it was to him a great pleasure to propose a vote of thanks to the President, not merely for the Valedictory Address they had just heard, but for his admirable conduct in the Chair during the past year. Of all the original Fellows of the Society he believed that none had been a more constant attendant at their meetings, or had the interests of the Society more closely at heart than Dr. Heywood Smith, and no one could fail to appreciate the patience, wisdom, and courtesy with which he had discharged the onerous duties of the office of President of the Society, while all would join in cordial wishes that he might long be spared to take part in their proceedings and give them the benefit of his presence and counsel.

The vote of thanks having been carried by acclamation, Dr. Heywood Smith, in acknowledging it, expressed the pleasure it had been to him to serve the Society.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, JANUARY 21ST, 1904.

JAMES BARR, M.D., F.R.C.P., President, in the Chair.

CEREBRAL TUMOUR.—CEREBRAL THROMBOSIS.

DR. WARRINGTON read a note on a case of cerebral

thrombosis clinically characterised by total aphasia, but with retention of consciousness. The necropsy showed that the softening had occurred in the region of distribution of the middle cerebral artery, and that it was in great part limited to the lower frontal convolution, temporo-sphenoidal and angular gyrus on the left side.

Dr. WARRINGTON also gave an account of a case of cerebral tumour. The initial symptoms were loss of recollection, hallucinations of smell and attack of pallor, with erection of hair on the left side of the face. Later the classical symptoms of tumour cerebri developed, being ushered in by an apoplectiform attack in which consciousness was lost for nine days. An exploratory operation was performed by Mr. Rushton Parker, the Rolandic area was exposed, revealing œdema of the sub-arachnoid tissue and softness of the brain, but no tumour or even marked tension of the brain. The operation afforded marked though temporary relief to the patient, who died four months later. At the autopsy a tumour was found occupying the basal ganglia and hippocampus major.

Mr. RUSHTON PARKER said that the operation he performed was done chiefly with the view to relieve tension supposed to be the cause of the optic neuritis. The piece of bone removed was replaced in fragments. The wound healed by first intention, and the patient's eyesight was restored and preserved. The patient lived nearly four months after the operation, and undoubtedly his life was prolonged and the progress of the tumour found after death was greatly diminished.

Sir WILLIAM BANKS then read a paper on

THE MODERN SURGERY OF THE PROSTATE,

an abstract of which will be found on page 81.

Mr. FREYER congratulated Sir William Banks upon his essentially practical paper, and endorsed what had been said respecting the admirable work of Sir Henry Thompson, for the use of the soft rubber catheter, together with washing out of the bladder, was a very great advance in the treatment of enlarged prostate. Mr. Freyer briefly referred to the various operative procedures which had from time to time been advocated in dealing with an enlarged prostate. He particularly mentioned castration, and as illustrating the uselessness of such a procedure, exhibited a prostate which he had removed from a patient upon whom castration had been performed five years previously. Mr. Freyer then dealt with the anatomy of the prostate, which, he said, consisted of two separate portions held together by a fibrous capsule, the whole being enclosed in a sheath formed by the recto-vesical fascia, much in the same way as the rind encloses the edible portion of an orange. In enucleating a prostate the gland is shelled out of the recto-vesical sheath, and, as the prostatic plexus of veins is for the most part embedded in the recto-vesical sheath, there should not be much hæmorrhage during the operation. He laid great stress upon the importance of ascertaining as far as possible the condition of the kidneys before attempting enucleation, for in long-standing prostatic trouble there was always a danger of suppression of urine, quite apart from the result of operative interference. If cases were more carefully selected and better prepared for operation the mortality in future would be less. Mr. Freyer finally described in detail the various steps of his operation.

Mr. REGINALD HARRISON said he would confine his remarks to the influence that supra-pubic prostatectomy as illustrated by Mr. Freyer's cases would be likely to have on the operative treatment of stone in the bladder, complicated with such a degree of prostatic enlargement as to render the patient incapable of fully emptying his bladder or of doing so with a catheter. In such cases the expectancy of a recurrence of stone after its removal either by crushing or by suprapubic cystotomy was very great. In fact, under these conditions the obstructing prostate might be regarded as the principal factor in the formation or re-formation of stone. He quoted examples where, after litholapaxy had been employed on repeated occasions for recurrence of bladder stone, the concurrent removal of both stone and prostate had been followed by the complete and permanent recovery of the patient in the fullest sense of the term. He exhibited a stone and prostate which he had removed the previous day from a patient who had undergone suprapubic lithotomy six months previously. He thought there were many cases where the stone and prostate should be removed as a primary operation. In fact, he had done so in several instances with excellent results. He said this without any prejudice to litholapaxy, which he regarded as the best and safest operation in uncomplicated cases of stone or where co-existing prostatic symptoms were not pressing. He did not think the combined operation increased the risk.

Mr. ROBERT BICKERSTETH spoke of the occasional great difficulty in removing a small and hard prostate, and asked Mr. Freyer whether in his suprapubic operation he had ever failed in an attempt to enucleate one of these prostates.

Mr. NEWBOLT mentioned three cases in which he had operated by the suprapubic method, twice successfully, the third patient dying from uræmia.

Mr. DOUGLAS CRAWFORD thought that in future the operation would be performed earlier while the prostate was comparatively small. He had not been satisfied with his results from castration.

Mr. RUSHTON PARKER said he could confirm Mr. Freyer's description of the so-called third lobe, as being an integral part of one of the lateral lobes.

Mr. THELWALL THOMAS spoke in favour of the perineal route, and said when the enlargement was not very great the prostate could, after free division of the capsule, be as readily enucleated as by the suprapubic method; this latter method he considered more applicable when there was considerable prostatic enlargement.

Mr. PAUL said his experience of complete enucleation of the prostate was limited to one case, a gentleman, æt. 70. The power of urinating had subsequently been normal. He said he was a firm believer in the value of catheterism in prostatic retention. In many cases nothing more was required, but in some a period came when operative interference was necessary. As regards double castration, he congratulated Sir William Banks on never having done it. In his experience the advantages claimed for it and for vasectomy had not been fulfilled.

CORK MEDICAL AND SURGICAL SOCIETY

MEETING HELD WEDNESDAY, JANUARY 13TH, 1904.

J. COTTER, M.D., F.R.C.S.I., President, in the Chair.

THE CHAIRMAN read notes of intestinal obstruction occurring in a woman, æt. 49, the result of carcinoma of the hepatic flexure of the colon, and exhibited the growth. The growth was excised, and the free ends of the intestines sutured together, but the patient died in twenty-four hours.

Dr. T. GELSTON ATKINS showed two ovarian tumours, both occurring in patients, æt. 23, and neither of them giving rise to any symptoms whatever except some nausea, aggravated by movement, though one tumour was of considerable size. Both patients recovered. Dr. Atkins also read notes of two cases of hysterosalpingo-oöphorectomy. One patient was a married woman, æt. 35, and on vaginal examination pus was found welling from the uterus. A laparotomy was performed, and an abscess found in each ovary, probably due to puerperal infection. A peculiar feature of the case was that each abscess opened directly into the uterus, the uterus itself and the Fallopian tubes being healthy. The patient made a good recovery. The other patient was æt. 53, and suffered from carcinoma of the uterus and ovaries. The diseased organs were removed, but the patient gradually sank and died in seven days from cardiac failure. She had suffered for years from tachycardia, and her pulse before the operation was never below 150, and after the operation never below 160. The diseased organs were shown.

Dr. N. HENRY HOBART read notes of a successful case of Cæsarean section. The patient was a primipara, æt. 24; height, 4 ft. 6 in., and the subject of lateral curvature. The external conjugate diameter measured 5½ in., and the true conjugate slightly over 3 in. The child was delivered by the feet (the head being fixed), 6½ minutes from the commencement of the operation. The uterus was flushed with saline solution and then sutured. The patient made a good recovery and the child also lived.

France.

PARIS, January 24th, 1904.

ACETONURIA IN CHIEDREN.

PERIODICAL vomiting in children is frequently, according to Professor Marfan, connected with acetonæmia indicating a disturbance in nutrition. A link in the chain of the oxydation of albuminoids of which the ultimate term was water and carbonic acid, acetone was accompanied by a number of other products, such as lactic acid, oxalic, acetic, formic, and butyric acids. It had been suggested, and with some reason, that acetone was produced by a disorder in the hepatic functions.

Acetonuria being remarked in diabetes and the coma of glycosuria, a considerable amount of gravity was attributed to its presence, but it existed also in auto-intoxications of intestinal origin, typhoid fever, cancer and certain cases of inanition.

In all these affections and conditions the digestive tract was compromised. In children there existed a rather rare syndroma characterised by periodic attacks of vomiting accompanied by absolute constipation in otherwise healthy children. The vomited matter contained acetone, and the breath had a special odour resembling chloroform or apples, yet the gravity of the case depended on the malady and not on the acetone; but in acute affections the convalescence should be watched, as the patient might be considered as liable to arthritism.

PHYSICOTHERAPY.

When in Paris those who are interested in physicotherapy would do well to visit the Institute of Dr. Joseph A. Rivière, No. 25 Rue des Mathurins, near the Opéra. Dr. Rivière has devoted his professional life to the improvement and development of this branch of medical science, and was the first to attempt the combination in one establishment of the latest and most perfected apparatus. Many of these are his own inventions, as may be seen from the following enumeration of the leading departments of his institute. Electrotherapy: Every model of high frequency apparatus Hydrotherapy: Nauheim baths, Rivière's massage under water, and carbonic-acid baths. Thermotherapy. Vibrotherapy. Mecanotherapy. Hydro- and aero-massotherapy. Obesity: apparatus Rivière. Phototherapy: Finsen apparatus, Rivière's electric light baths and reflecting apparatus, treatment of pulmonary tuberculosis by means of intense luminous clusters. Aerotherapy. Radiography. Radioscopy. Kinesitherapy and gynæcological electrotherapy.

It will be seen by an inspection of his institute and from the articles he has contributed to various publications, and by the reports of his addresses before medical conventions, that Dr. Rivière has anticipated many of the recent experiments in treatment of cancerous and obstinate tumours. I may mention here his paper read before the International Medical Congress of Electrology and Radiology at Paris in 1900; his communication to the Fourteenth International Medical Congress at Madrid in 1903; and his address to the Académie Nationale de Médicine, at Paris, on December 8th, 1903. In recognition of these services Dr. Rivière received last October the Chevalier decoration of the Légion d'Honneur; and on this occasion a banquet was given to him by many members of the profession, including Professor Lancereaux, President of the Academy of Medicine.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 23rd, 1904.

THE GENESIS OF SYPHILITIC GUMMATA.

A CASE published in the *Deut. med. Woch.* by Dr. Kulisch, of Halle, is interesting from an etiological point of view as regards the origin of gummata. In this case a gumma formed at the point when hydrarg. salicyl. was injected. In November, 1895, the patient was treated in Russia for an ulcer on the penis that healed rapidly.

As no further symptoms developed, he married in July, 1896. Soon afterwards, however, mucous plaques appeared on the palate, tongue, and lips, for which local treatment was applied, and internally potassium iodide was given and mercury salicylate by injection into both gluteal regions. In May, 1897, the patient, who was then æt. about 30, consulted the writer on account of his wife, who had given birth to a dead decomposing syphilitic fœtus at the eighth month. On examination, luetic plaques were found on both tonsils, numerous pigmented patches on the trunk, and several painless nodules in the gluteal musculature of both sides. Under a course of local nunction of four weeks, recovery took place, and another course of three weeks was carried out six months afterwards. In May, 1899, there were scaly papules on the glans penis, weeping papules on the scrotum, and large pustulous syphilides on both legs. These symptoms also disappeared under potassium iodide internally and an inunction course of several weeks. In December, 1899, the patient again came under treatment for a solitary gumma situated in the eft gluteal muscle, with commencing softening and spontaneous rupture in some spots. After a month's treatment healing took place with central funnel-shaped contraction. At the end of June, 1900, there was an ulcerating gumma on both fauces, and one on the right buttock. Both receded after a three weeks' inunction course, and potassium iodide internally, and the patient went abroad again. Ten weeks later he returned with a tumour in the same spot; the skin over the tumour was perforated in some places, and secretion was taking place. This condition also disappeared after several weeks of treatment, so far that in the circumference of a central contraction an absolutely painless tumour, the size of an apple, remained. In June, 1901, the patient returned, as the tumour had grown and had broken out in the same places. The growth was now punctured, and the mass scraped out. This was shown microscopically to be detritus and cells undergoing fatty changes, and chemically mercury was found to be present. As surgical treatment was declined on the part of the patient, specific treatment was again begun. After six weeks' treatment some induration was still present. Up to May, 1902, there was no relapse, and the patient was in good health. In the foregoing case it must be remarked that even after the lapse of five years, remains of the early hydrarg. salicyl. injection were still present in the musculature. These injections had caused inflammatory symptoms at the point of injection, and had started chronic changes in the muscular tissues that had formed the substratum for the later tertiary disease. The exciting

causes for this tertiary disease were the very late specific primary treatment and the irregular mode of life of a traveller.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 23rd, 1904.

STENOSIS OF THE LEFT PULMONARY ARTERY.

JELLINEK brought before the Society a patient with all the symptoms of stenosis of the left pulmonary artery. The patient, æt. 28, was taken ill in April, 1902, with inflammation in the left side, involving the diaphragm and lower part of the lung, evidently of a tuberculous nature. At present there is great shrinkage in the left side of the chest, and percussion is generally dull all over. Heart is two fingers' breadth displaced to the left; apex beats strong and a finger's breadth outside the left mammary line over the mitral and tricuspid valves. A systolic murmur was distinctly heard both in front and behind the inter-scapular space. The second sound was greatly accentuated, both to sight and touch. The radial pulse had nothing particular to note, with a tension of 110 mm. There was no positive venous pulse to be observed, nor dilatation of the heart. Examination of the sputa revealed tuberculous bacilli. The Röntgen rays confirmed the displacement to the left of the mediastinum.

The whole resembled an indurated left side pleuritis. The localisation of the loud systolic murmur and the absence of the usual phenomena were in favour of a mitral or tricuspid insufficiency. Against the possibility of aortic stenosis or aneurysm was the condition of the pulse, the appearance of the diaphragm and general percussion. The symptoms generally confirmed the diagnosis that a stenosis existed in the left pulmonary artery.

HÆMATURIA FOLLOWING ULCERATIVE TUBERCULOSIS OF THE KIDNEYS.

Schmidt exhibited a male patient, æt. 32, who was confined to his bed on November 3rd. After carrying a heavy load upstairs he suddenly complained of great pain in the right testicle, which radiated down the inside of the leg and upwards over Poupart's ligament. One hour after he urinated pure blood. According to the history nothing in the uropoietic system could account for this phenomenon as there was no previous disturbance in the emission of urine, pain in the renal region, nor any deviation in the constituents of the urine, which was normal in quantity. The objective examination was against tuberculosis, while the family history gave nothing to support that suspicion. A differential diagnosis and exploration of the blood with excessive pain in the right side of the testicle was at first assumed to be hyperæsthesia with possible right renal hæmorrhage, which was confirmed with the cystoscope. There was no tumour or enlargement to be detected, while nephrolithiasis could scarcely be entertained without some previous initial prodroma. After further exclusion it was concluded that the case was renal papillary tuberculosis of an ulcerative form. To confirm this, tuberculin of the old style was injected, commencing with 0·001 gramme without any appreciable reaction; later 0·003 was injected, which commenced to show signs of activity after twenty-four hours.

The patient was confined to bed and treated with adrenalin, tannin, &c., up to November 30th, when it was resolved to extirpate the right kidney, which was successfully accomplished.

The pathological examination of the kidney proved it to be a disseminated form of tuberculosis, where small groups of greyish tubercle was scattered throughout different parts of the cortex. There was also a caseous degeneration at the mucous orifices in the pelvis of the kidneys.

Schmidt thought this was an important case to guide us in many of those obscure and sudden attacks of hæmaturia whose etiology was doubtful and tuberculosis suspected.

Schlesinger reported another case of renal hæmorrhage for which he extirpated the left kidney, and found on examining it a small tumour not much larger than a pea, but of a carcinomatous nature.

The Operating Theatres.

LONDON HOSPITAL.

CHOLELITHIASIS.—EMPYEMA.—EXCISION OF GALL-BLADDER.—Mr. F. EVE operated on a woman, æt. 36, who had been suffering for eighteen years from attacks of so-called digestive trouble, several attacks of pain referred mainly to the epigastrium, associated with vomiting; on one occasion she was slightly jaundiced. There had been a severe attack of pain a few days before admission and pyrexia, the temperature being about 102·5, but no jaundice. There was tenderness below the ninth costal cartilage on the right side and part of the rectus on the same side was extremely contracted with resistance beneath it. Cholelithiasis and empyema of the gall-bladder was diagnosed, but Mr. Eve pointed out that it was impossible to give a definite opinion from physical examination without an anæsthetic, owing to the tonic contraction of the abdominal muscles. The resistance beneath the upper part of the right rectus was, he thought, just as likely to be a Riedel's lobe as an enlarged and thickened gall-bladder. An incision was made in the usual situation, and this exposed a Riedel's lobe extending down to midway between the costal margin and the umbilicus. On raising it the gall-bladder seemed to be situated entirely beneath it and surrounded by adhesions to the omentum and stomach. These were separated with the finger; the gall-bladder was found to be distended, and its walls much thickened. It was aspirated, and pus drawn out; it was then incised, many stones were removed, and the cystic duct appeared to be obliterated. The thickened gall-bladder was therefore removed and a ligature placed on its proximal end. The peritoneum was too thickened to allow a flap being formed to cover the stump. The operator's and assistant's hands were now cleansed before exploring the condition of the common duct. The foramen of Winslow was found to be closed by adhesions which gave way to the finger. The gastro-hepatic omentum, which was greatly thickened and shortened, was brought to the surface by the finger beneath it; a stone was felt at its upper part; this was cut down upon, excised and removed; it was found to occupy the cystic duct on its junction with the common duct, the latter being clear. The small incision was closed by suture, a drainage-tube fitted with gauze was carried downwards towards the hilum of the liver, and packed round with gauze, and the abdominal wound closed with the exception of an opening in the centre for the drainage-tube. The entire operation, which was well borne, lasted one hour. Mr. Eve said that the case emphasised many facts of clinical importance. When a patient presented herself with hepatic colic and a rounded swelling moving with respiration was felt in the region of the gall-bladder, it was usually assumed that it was the gall-bladder; in a majority of instances, however, the swelling was a Riedel's lobe, for in cholelithiasis the gall-bladder was more often

contracted than distended; the contraction of the abdominal muscles prevented a minute examination of the swelling, except under an anæsthetic. Again, pain referred to the epigastrium and sometimes to the left costal margin might lead to the diagnosis of a gastric affection, were it not borne in mind that when the stomach is adherent to the gall-bladder the pain is usually referred to the above-mentioned locality, and not to the right hypochondrium and right shoulder-blade. He believed that when the gall-bladder was greatly thickened, suppurating, and its duct probably obliterated, the organ was not only obsolete, but might prove a source of danger to the patient, and its presence retarded convalescence; he therefore removed it, provided, as in this case, there was no evidence of obstruction to the common duct, but even if there were, the common duct could be opened and drained by a tube sewn to the margin of the incision. Another point of interest in this case, he said, was the very great thickening and shortening of the gastro-hepatic omentum, which rendered the structures within it almost unrecognisable; its section was homogeneous, like brawn. These cases, he thought, almost invariably did well, owing to the fact that the "kidney pouch," in which the trouble occurs, is practically shut off from the rest of the peritoneal cavity. The complication most to be feared, he considered, was pre-operative infective cholangitis, followed by hepatic abscess. In operating on septic conditions of the abdomen, care, he pointed out, should be taken to thoroughly cleanse the hands and to obtain clean instruments before exploring any uninfected region of the abdomen within the neighbourhood, this being often necessary.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXX.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

ALDERNEY MANOR SANATORIUM, PARKSTONE, BOURNEMOUTH.

MUCH discussion has recently taken place as to the best form of sanatorium for the consumptive, and much can be said in favour of the "separate or châlet system." Dr. Johns' sanatorium is an excellent example of a small private institution worked on the "hut" method, and well exemplifies the merits and difficulties of such an arrangement.

Dr. Johns has had a comparatively extensive experience of sanatorium management in Bournemouth and its immediate neighbourhood. In 1896, he commenced "open-air" treatment at Sunny Mount, a small house at Meyrick Park. Later he transferred his patients to Stourfield Park Sanatorium, which was, as regards structure, practically a large hotel. Quite recently he has developed Alderney Manor.

The present sanatorium is well situated about three miles from Bournemouth at an elevation of 210 ft., and in open country. The site is to all intents and purposes a clearing of about 30 acres in the midst of a pine forest. The estate consists of 600 acres of pine woods and heather-covered land. Many thousands of acres of open country surround the estate. The New Forest is near at hand; the River Stour can be easily reached; and the sea is not far distant.

As already indicated, the sanatorium is laid out on the "hut system." The huts, single or double, are one-storeyed buildings throughout. Neither verandahs nor "liegehallen" are provided. An absolutely open-air existence is insisted on.

The sleeping huts are built of galvanised iron, lined with compo or match-boarding, and interlined with felt. In some cases the matching is covered with "salubra." The furniture is of the simplest and has been specially designed to be non-dust-collecting. The windows are large and numerous, and so arranged that the patient can always be provided with a thorough current of air, and yet be protected from draught.

One corridor-building containing several apartments has been reserved for ladies, and here the exposure to fresh air is not so complete, although there is still good ventilation, a window being opposite each door, and the bedrooms placed only on one side of the corridor.

The dining-room is an excellent, airy, well-lighted, and cheery room, standing by itself with windows on three sides.

Dr. Johns devotes himself entirely to the conduct of his colony. Every case receives close personal attention. The following points are particularly observed:—

1. The patient breathes fresh air at all times, day and night.

2. An abundant diet of mixed foods is provided and in some cases judicious "over-feeding" is enforced. Prizes are given to those who increase most in weight.

3. Exercise and rest are systematically regulated, according to individual necessities.

4. The patients are wholly in the charge of the doctor, supported by a staff of trained nurses. The feeding, which forms a conspicuous part of the treatment, is personally superintended by the doctor, who presides at all meals.

Dr. Johns informed us that he finds much benefit results from the judicious use of the "sun bath." An old walled-in garden forms an excellent exercise ground and an admirable "sun garden" for gentlemen. Another "sun-bath" has been formed for ladies. In these so-called "baths" patients lie completely exposed to the light and heat rays of the sun, even at such times of the year when most persons are unpacking their winter apparel.

Extensive provision is made for the comfort and amusement of the patients. There are two croquet lawns, sea-bathing may be enjoyed under medical supervision, and salmon and other fishing may be indulged in, and even a fair amount of shooting is available.

We were surprised to find a band-stand on the grounds, which we learnt was sometimes used by the musicians from a neighbouring village.

There are good stables, and patients may keep their own horses if they so desire. Arrangements have been made whereby gentlemen may gain experience in the management of landed property, and so secure knowledge which may equip them for a useful outdoor occupation.

It will perhaps be of interest to quote from a copy of the Rules as presented to every patient:—

"1. Patients are requested to expectorate only in the receptacles specially provided for the purpose. They must never spit on the ground, or in their handkerchiefs, as by these means the disease is spread. Flasks are provided for patients when out walking.

"2. As it is essential that patients should breathe only pure air continually, they should not frequent any place of public resort. Whilst under treatment they are expected to take only such exercise as is prescribed by the doctor, and they are requested not to go into the town, ride in public vehicles, or enter houses or shops without his permission.

"3. For the same reason patients are asked not to congregate in each other's rooms or huts.

"4. Patients must rest at least one hour before every meal.

"5. It is considered much better for the patients not to see visitors except very occasionally. The doctor will be obliged if patients will make this clear to their friends.

"6. The food is specially ordered to assist the cure of the patient in the shortest period. The patient should, therefore, exert every power of will to eat the quantities prescribed by the doctor.

"7. During the season shooting will be allowed in the woods, Tuesday mornings, Thursday and Saturday afternoons. Shooting will not be allowed at any other time, either in the field or near any building.

"8. Patients must be in bed by 9.30. All lights to be extinguished at 10.30."

The administrative part of the sanatorium consists of a quaint old building, the Manor House, built after the early English style, and here Dr. and Mrs. Johns and the other members of the staff reside. The bells of all the sleeping huts and from the head nurse's room ring in the doctor's bedroom.

It must be admitted that the general view of the sanatorium is peculiar and, architecturally, not altogether pleasing; but if æsthetic considerations have been sacrificed, rigorous insistence has been made on the importance of securing the maximum of exposure to open air.

The drainage system is connected with the newly-constructed main sewer. The water comes from the Poole Water Supply Company. Heating is provided for by Choubersky's stoves, which burn anthracite.

Accommodation is available for above twenty-five patients.

The fees are four guineas a week, inclusive of medical attendance, the only extras being personal laundry, wine or spirits, medicine, and special nursing.

The sanatorium is not readily accessible. It is about twenty-five minutes' walk from Constitution Hill on the Bournemouth to Poole tram route. Parkstone Station is two miles distant, while Bournemouth is three miles away. A carriage can always meet patients by appointment.

REGISTERED FOR TRANSMISSION ABROAD.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 27, 1904.

ST. BARTHOLOMEW'S HOSPITAL.

THE question of the reconstruction of St. Bartholomew's Hospital, which has been before the public for so long a time, appears to be on the point of settlement. The possibility of an extension of area on the present site has been precluded by the purchase by the Post Office of the whole of the ground rendered vacant by the removal of Christ's Hospital School to more salubrious country quarters. The authorities of the Hospital, both medical and non-medical, have agreed upon a course of action, the details to be discussed at a Mansion House meeting on the 26th. The main feature is the removal from the present site of all but strictly hospital buildings, such as the medical school, nurses' home, and other administrative and official offices, all of which would be located at a convenient distance. In this way the present site could be devoted to wards, operating theatres, out-patient rooms, clinical laboratories, and so on. This way out of the wood is fairly obvious, but surely it can be hardly less costly than would have been the prompt purchase of the vacant Christ's Hospital site. The value of the present site of St. Bartholomew's is, roughly speaking, about a million pounds. The appeal about to be made to the public is for some £500,000 for reconstruction, and to that will probably be added some £350,000 for the purchase of an auxiliary site and the construction of extra-hospital buildings. There is little doubt that the money asked for will be forthcoming, although at the same time it is equally certain that the absorption of so large a charitable public gift must necessarily temporarily diminish the resources of other medical charities. Few will dispute, however, the desirability of placing St. Bartholomew's Hospital on a level with the highest modern standards of scientific hospital construction and administration. Let St. Bartholomew's, a national institution, be second to none in its completeness of equipment on all points. The mere profusion of expenditure, it need hardly be pointed out, is by no means a necessary index to the attainment of a high ideal of perfection. In all walks of life success is most likely to result from prudent, cautious and well-informed counsel and consideration. In the steps hitherto taken with regard to St. Bartholomew's Hospital we venture to think that two defects have been conspicuous, namely, the withholding of evidence on which decisions have been made, and the strong partisan nature of conflicting proposals. The report of the first Mansion House Committee was a document unworthy of the administrators of a great public trust. The views of the medical staff of the hospital were revealed to the public by the enterprise of a private individual. The proposal of Sir Henry Burdett to build a large modern hospital has been rejected. There may be excellent grounds for all that has been done, but our contention is that the public should be fully informed of every argument "pro and con." bearing upon every fresh development and every fresh decision. From this standpoint we maintain that the question of "partial removal" has never been adequately discussed by the authorities of St. Bartholomew's. The Mansion House Committee dismissed the matter curtly and contemptuously. The medical staff, in their latest report, condemn the proposal in general terms, but a problem of that kind, although it may be thereby shelved, remains unsolved. A business man has detailed reasons for all he says and does, and there is no reason for any other attitude on the part of the business men who have been entrusted with the management of the greatest medical charity in the Kingdom. The present site could be sold for about a million, and out of the purchase money a palatial building and grounds could be secured in the suburbs of London, while enough accommodation could be left behind in Smithfield for the needs of the day population

of the City. The "Blue Coat" boys have been moved into the country for the sake of purer air. If that be desirable for schoolboys it is surely far more necessary for invalids. The tendency of medicine is to trust more and more to country air. It is questionable whether the surgeon of the future will sanction serious operations in a town environment. If all tuberculous diseases were henceforth declined at St. Bartholomew's, considerable relief to the hospital accommodation would speedily follow. Yet what conscientious surgeon would keep tuberculous patients in the City when he could send them to an airy suburb or to the country? Then, again, the London University has made a bid for the centralisation of medical teaching. Until the issue of that movement is indicated the wisdom of founding a costly medical school in the heart of London may well be questioned. It may be, as we have already said, that the balance of argument may be in favour of retention of the ancient site by St. Bartholomew's. We maintain, however, that the grounds of objection to a scheme of partial removal have never been adequately presented to the public. The demand for half a million or more should be accompanied with a minute statement as to the why and wherefore of its destination, with the fullest and most precise information as to the action of the Hospital authorities throughout the whole of the somewhat complicated recent proceedings with regard to the reconstruction proposals.

PHTHISIOPHOBIA.

DURING the last few months we have been able to furnish a series of unbiassed reports on various British sanatoria, each account being the outcome of a special visit by our Special Medical Commissioner. A study of these articles will make clear the widespread influence of, what we may speak of as, institutional effort in the arrest of pulmonary tuberculosis, and a mitigation of the evils attendant on such disease. Both public and professional attention in almost every part of the country is being focussed on this matter by the rapid uprising of extensive, and often elaborate, and sometimes even palatial, establishments for the care, and, it is to be hoped, the relative cure, of the consumptive. Public notices meet the eye at almost every turn warning of the danger which arises from the expectoration of an ignorant and neglectful consumptive. The greater the warning the more conspicuous appears the danger. The ordinary layman is oftentimes much perplexed at the seeming contradictions of medical directions, and certainly, in regard to the advice respecting tuberculosis he may well stand in perplexity and linger in doubt. Amidst conflicting voices it is hardly to be wondered at that a condition conveniently designated "phthisiophobia" is wont to be developed. The more unknown and ill-defined the danger the greater is the fear. The declarations of not a few would-be leaders of medical thought and hygienic progress have recently gone far to bring about conditions which are in imminent danger of acting prejudicially on the consumptive. We venture to think that the time has come when medical men should take a part in securing measures which may allay the alarm of the public, rather than foment a tendency to panic which must necessarily mean paralysis in action and poverty in thought. In many quarters there exists an exaggerated fear of the presence of the consumptive. This would appear to be particularly the case in certain districts of America, and has probably arisen from an ill-regulated and somewhat precipitate action of officials, whereby a declaration was recently issued stating that pulmonary tuberculosis was a dangerous contagious disease, and immigrants or aliens so afflicted must be debarred from all ports of the United States. It is to be hoped that no such reckless views will receive approval in this country until at least we have secured scientific evidence and sound clinical experience warranting such action. In the State of New York official phthisiophobia has developed to such an extent that it would now appear to be difficult to provide for the suitable establishment of sanatoria in the vicinity of a community. It is well that we should do our utmost to discourage action merely based on the selfish element of fear. Even now those engaged in the treatment of phthisis know that the development of what we may call a State phthisiophobia is in danger of staying progress. Widespread fear of consumption prevails among many, and in certain circles there is likelihood of a consumptive being shunned as a leper, and treated as an outcast from society. In the anti-tuberculosis crusade which is being so actively carried on in Europe, and particularly in this country, there is the utmost need for wise discernment, close observation, strict scientific procedure, and every movement likely to induce panic must be strenuously resisted. After close study of the expressions of recent opinion and a careful investigation into the conduct of measures designed to arrest tuberculosis, we have no hesitation in warning against the well-meant but injudicious and, we venture to add, ignorant advocacy of certain repressive procedures which have their origin in personal, public, and, we are sorry to add, professional phthisiophobia. To all such fear-fanned fanatical agitations we can only oppose the firm force of sound education.

PARATYPHOID FEVER.

IF there be one disease which, from its prevalence, its importance, and its protean character presents a host of difficulties to the physician, that disease is typhoid fever. Other diseases have their own intricacies and present their own puzzles, but none are quite so alluring and evasive as typhoid fever. Its insidious onset, its erratic course, its equivocal symptoms, its startling surprises, its high fatality, all combine to make it at once the bane, the bugbear, and the stumbling block of the practitioner of medicine. A most unfortunate change was made in the nomenclature of the disease by

the substitution of "enteric fever" for the old-time "typhoid fever"—a substitution that has, moreover, become fixed in the popular mind by repeated perusal of the casualty lists during the South African War. "Typhoid fever" may not have been good, but it was, at least, non-committal as regards the pathology of the disease, whilst "enteric fever" more than suggests that it is an affection of the alimentary tract, and of that alone. Had the nosologist waited before re-naming the disease he would have had to confess that typhoid fever is an infective process in which the specific bacilli pass into the blood-stream from the intestine and reach many of the important viscera; and, moreover, that the characteristic phenomena of the disease are due to the pathological changes thus brought about. Now this is far more than a mere academic contention. It involves the whole conception of the nature of the process which we indicate by the term typhoid fever. This process is complex, and its real complexity is only just beginning to appear. For typhoid fever is now known to comprise at least two distinct processes, and the probability is that even more may be differentiated as the study of the question progresses. The *Bacillus typhosus*, which held rank in the bacteriological hierarchy as one of the specific disease-producing bacteria, has been found not to be the causal organism in all that group of cases that now rank as typhoid fever, for in quite a number of cases recently not only has *Bacillus typhosus* not been found, but other organisms of the *Bacillus enteritidis* or Gärtner group have been discovered in such situations and in such numbers that there can be little doubt they play a leading *rôle* in the disease-process. The typhoid bacillus stands at the far end of a long series of organisms closely allied to *Bacillus coli communis*, and one or more of these intermediate forms has been demonstrated in several different cases as the predominant factor. Three interesting problems arise. First, are all the Gärtner bacilli that have been found in these cases genetically the same? Secondly, is the typhoid bacillus only a specialised Gärtner bacillus? And, thirdly, are the cases of disease in which the Gärtner bacillus occurs different in their clinical features from those in which the typhoid bacillus occurs? It is to this third, and very important, question that we address ourselves. Paratyphoid fever, as it has been called, is a disease that has many clinical features in common with typhoid fever; continued pyrexia, rose-spots, enlargement of the spleen, diarrhœa, and hæmorrhage from the bowel have all been noted. On the other hand, agglutination of cultures of typhoid bacilli does not occur when the blood serum of the patient is brought into contact with them. But—here is the important point—the blood from these cases does agglutinate various strains of Gärtner bacilli. It, therefore, contains agglutinins, not the specific agglutinins of *Bacillus typhosus*, but those of one or more varieties of *Bacillus enteritidis*. This, it cannot be denied, is strong evidence of the specific part played by *Bacillus enteritidis* in the production of the disease, and it also helps to explain why Widal's reaction is not given by all cases of (apparent) typhoid fever. The presumption is that the latter cases are not examples of typhoid fever proper, but of paratyphoid fever. Now this latter disease, closely resembling typhoid fever as it does at the bedside, is, as a rule, a milder affection, and though it may run a long course it generally tends to recovery. Moreover, attention has been directed several times lately to cases in which after death from clinical typhoid no changes have been found in the lymph-follicles of the intestine, and the suggestion has been made by Luksch that these cases belong to the "paratyphoid" group, and that not only do these cases differ from typhoid fever clinically and bacteriologically, but that they present, in some instances at all events, distinctive gross morbid phenomena. The further elucidation of these questions will be awaited with much interest, as they involve points not only of the highest scientific interest but of the greatest practical importance. If typhoid fever prove to be a name applied, not to a homogeneous disease, but to a heterogeneous collection of closely-allied diseases, the explanation of much that is at present involved in obscurity will be forthcoming. For the present it may be said with some conviction that paratyphoid fever has established its claim to recognition as a distinct entity; but that is all. What its features are, and what it may include, remain to be worked out. Perhaps one of the most striking developments will be an explanation of the relapse. We feel ourselves that no solution of this problem would be so satisfactory as that which demonstrated that the relapse in typhoid fever was due to fresh infection of the patient's tissues by a different, but closely-allied, bacillus from that which caused the original disease. The laurels of Jenner and Stewart await the investigators of paratyphoid fever.

Notes on Current Topics.

An Age-Limit to Medical Appointments.

THE Court of Contributors to the Royal Infirmary, Edinburgh, have recently very definitely asserted their authority by imposing an age-limit of sixty-five on professors in the University who have also charge of wards in the Infirmary. The decision was the natural sequence to a former decision of the Board of Management, which imposes a similar age-limit on the ordinary physicians and surgeons to the Infirmary, omitting the University professors. The new rule is bound sooner or later to give rise to difficulties, inasmuch as there is no age-limit in the University, nor any obligation to compel a professor who is retired at the Infirmary at the same time to vacate his Chair in the University. Consequently, a professor who has passed sixty-five will find himself in the position of teaching his students without the power of giving them the necessary clinical

instruction. As to the advisability of an age-limit in hospital appointments, opinions will doubtless differ. Many instances can be brought up to show the tendency of men to cling to their posts even after they are physically or mentally incapable of discharging the duties of them; and, similarly, many instances could be brought up in which compulsory retirement at a fixed age would lead to the loss of the best men. The system in vogue in many universities of electing a man for a term of years, with power to re-elect him if it is considered advisable, is, to our mind, the best method that can be obtained, as, if it is carried out as its originators intended, the man who is past his work will be as effectually removed as he would be by an age-limit, while the capable man will be left to discharge his duties. At the same time, we of course recognise the personal difficulty that often arises to the shelving of a man who may perhaps be more or less dependent on his appointment for his livelihood.

Microbes as Instruments of Warfare.

SOME interesting discussions and reminiscences have been called forth by the rumour which was current a few weeks ago that the Macedonians had decided to make use of virulent plague cultures in their fight against the Turks. It is very doubtful whether plague bacilli could be of any avail if used by the particular method suggested—infection of the water supply. The life history of the microbe in question is not yet sufficiently known to say whether plague is at all a water-borne disease, but it is unlikely to be so to such an extent as to render possible the poisoning of the water supply of a great city. It is above all things a dirt disease, but it is too soon to dogmatise regarding its methods of spreading. The use of micro-organisms in warfare, though, of course, at the present day contrary to the methods of civilised nations, has always been practised among uncivilised peoples, and still more by civilised in their attempts to exterminate uncivilised peoples. One of the commonest means of poisoning weapons was dipping their points in putrefying material with the view of producing a septic wound. In the English suppression of rebellions in Ireland in Elizabethan times thousands of the natives were swept away in epidemics accidentally introduced, and the same thing occurred at a later period among the Red Indians of North America. As late as the Napoleonic wars terror was spread through the North of France by the rumour that England was about to attempt to introduce plague to those regions. An interesting document relating to this has just seen the light in Paris. It is a circular addressed to the officials of the Channel ports by the Naval Commissary at Boulogne, stating that the English Government was about to throw upon the French coasts several hundred bales of wool collected in a country where plague was raging. It goes on to give strict directions as to the destruction of any such bales. The story had, of course, no foundation in fact, and is about as near the truth as many of the tales commonly believed in England at the same period concerning the character of Napoleon.

One-Sided Reciprocity.

THANKS to the mandamus of the Privy Council we have a reciprocity understanding with the Italian Government in virtue of which—and very much against the desire of the General Medical Council—Italian graduates are admitted to registration in this country. That formality having been complied with, at the moderate and inclusive fee of five pounds, the same as for British registrants, the Italian physician has the run of the country. He acquires a medical status in that he can sue for fees—whatever that may be worth—and can tender evidence in a court of law at the risk of being heckled by a hostile counsel, over whom, however, a foreigner has the advantage that he need not understand an embarrassing question unless convenient. In return for all these privileges, British practitioners are entitled, or are at any rate allowed, to exercise their calling in Italy. It would seem, however, from a statement made a few days ago in the Italian Chamber, that foreigners are entitled to practise only among their fellow-countrymen; in other words, the privilege conceded to them is narrowly hedged in. This is hardly reciprocity on all fours, and reciprocity, as the Irishman said, must not be all on one side. If strictly interpreted, the British practitioner would not be justified in prescribing for citizens of the United States, since they are not under the same flag, still less for a native Italian. Admitting that in all probability no British practitioner is very keen on ministering to the medical requirements of the natives, seeing that they, for the most part, pay the smallest fees, the question of principle remains. We heartily approve the idea of reciprocity: indeed, the prohibition of the foreign practitioner who only aspires to treat his own countrymen is the *reductio ad absurdam* of protectionism, and marks a big step backwards compared to the intelligent eclecticism of the Middle Ages. Nevertheless, we would urge upon the General Medical Council in future to scheme to do what it can to secure real reciprocity, and not to exchange the whole for the part.

Diphtheria Antitoxin as a Prophylactic.

IT has long been the custom with those who best know the value of antitoxin in the treatment of diphtheria to make use of the serum as a prophylactic among those exposed to the disease. For instance, most physicians, in diagnosing diphtheria in one child of a family, are in the habit of treating the other children with small doses of antitoxin, with a view to producing immunity. And when a case of diphtheria appears in a ward of a children's hospital, it is usual to adopt the same course in regard to the other children in the ward. In some hospitals it has, however, become the habit to go further, and to use antitoxin systematically on all children, whether diphtheria is known to be present or not. In particular is this the case in the Boston Children's Hospital, and the Hospital

for Sick Children in Toronto, and Dr. Graham, in a recent paper, (*a*) publishes observations of great importance made in the latter hospital. It appears that for many years this institution, which does not receive infectious diseases of any sort, was never quite free from diphtheria, and it is calculated that on an average there were annually no less than eighty-four cases. Commencing in July, 1902, 500 units of antitoxin were given regularly to each child every three weeks, with the result that during the ensuing six months there was not in the wards a single case of the disease. This record is the more remarkable since both a doctor and a nurse suffered from diphtheria, and though they went about for several days before a diagnosis was made no child became affected. Dr. Graham's production of immunity is so striking in its success that it ought to go far to establish similar methods of procedure in other hospitals for children where it is found difficult to keep free of diphtheria.

"The Mystery of Sleep."

DIVINES rush in where physiologists fear to tread, and if only physiologists were not so intent on studying the phenomena of sleep they would see that there was really no need for study at all. Everything is as clear as daylight. The Rev. Dr. Bigelow has plumbed the depths of sleep, and has initiated us into its mysteries. After reading his book no one need interest himself in such details as whether the cerebral arteries contract or dilate during sleep, why blood-pressure falls, and how it is that voluntary nervous activity passes into abeyance. Sleep has generally been assumed to be a device for giving tired Nature rest, and affording the tissues an opportunity for recuperation. This assumption, however, amounts more or less to rank blasphemy, according to Dr. Bigelow, for it suggests that the Creator has fashioned us so imperfectly that we need to make up for the deficiencies by wasting precious time in sleep. Other created bodies need no rest; the planets whirl ceaselessly in their appointed spheres, and the sun never takes a day off. No, the need of sleep is moral, not physical; slumber gives to the soul the opportunity of a little jaunt to the spirit-world. There it has the opportunity of meeting other (temporarily) disembodied souls, and also of communing with the spirits of the great dead. From this period of refreshment the soul returns rejuvenated, for do we not find the morning the time of greatest spirituality? "It is then that we feel the charms of Nature most keenly, that we are most disposed to extenuate the misconduct of friends and neighbours." Some breakfast-tables that one knows do not always exhibit these admirable traits; perhaps the souls of these families go to other than Elysian fields during the night-time. The same soul-vagaries happen in lunacy. The madman is brought to his condition by "inordinate ambition, vanity or greed," and the removal of the soul from the terrestrial husk "resembles the operation of sleep, and is a real and usually unappreciated evidence of divine mercy." Most alienists will be disposed to agree with the last statement, so far, at least, as it asserts that the mercy is unappreciated by the sufferer. It is little less than extraordinary that pseudo-philosophic froth of this kind can be stirred up by the eccentric antics of twentieth-century divines, and one feels that the reverend doctor would find his views expressed in certain papers by Lowell that are called by a name resembling Dr. Bigelow's own, in which we are told that—

> "A merciful Providence fashioned us holler
> In order we might our principles swaller."

(*a*) *Canadian Practitioner*, December, 1903.

A New "Trust."

PEOPLE are fond of sneering at medical etiquette, and the laws written and unwritten by which we bind ourselves in our relations with them and with each other. If they would only take the trouble to inquire they would find that the despised "etiquette" is framed far more in their own interests than in ours, and that the greatest sufferers, were these self-imposed restraints removed, would be themselves. Do they realise, one wonders, the abnegation that is placed on the author of a discovery in medicine by being obliged to deny himself all private property in his discovery? Musicians and writers have their copyrights; inventors their patents; business men their trade-marks; the doctor—nothing. If people wish to go into the question how this benefits them, let them pay attention to the outcry that is being raised on the other side of the Atlantic by the proposed amalgamation of three firms to form an "antitoxin trust." Commercialism rules stronger among our fellow Anglo-Saxons than it does among ourselves, and these firms see that by a judicious arrangement they may increase the profit on the sale of antitoxin, of which they have the monopoly of manufacture, by a hundred per cent. Trusts of this kind are considered legitimate commercial enterprises when they affect soap, sugar, or tooth-picks, but when they touch medicinal remedies they become "iniquitous." Now that the American public are alive to what monopolies in remedies of real value would mean to them, it may be hoped that they will be a little less inclined to favour the unblushing quackery that flourishes in their midst, to the great profit of the charlatan and the great loss of the people. One cannot refrain from quoting the following from a contemporary that writes on the antitoxin trust:—"With a cynical effrontery which would be impossible in any other country, they have announced their determination to enter on this traffic in human life without further delay." Quite so, but what is sauce for the goose is sauce for the gander, and little as one sympathises with the antitoxin trust, it will at least deal in wares that are of value and will save life, which is more than can be said for those rogues who at present fatten on the credulity of their fellows. The antitoxin trust will do nothing but good if it brings home to our trans-Atlantic cousins the danger of placing

their health requirements in the hands of selfish and irresponsible individuals.

Adrenal Hæmorrhage.

THE functions and pathology of the suprarenal capsules have long proved an attractive subject for pathological research. The connection of these glands with that mysterious malady, Addison's disease, has, no doubt, given added zest to the work, but, apart from this affection, there are other conditions of the adrenal bodies, notably hæmorrhage, the pathology of which is but little understood. Four cases of adrenal hæmorrhage have been recorded by Dr. Leonard S. Dudgeon, (*a*) in whose paper the whole subject is discussed. All the cases occurred in young children under the age of seven. Perhaps the most striking point associated with the condition is that it is seen in the most varied diseases, and this has also been noticed by other observers. Some of the cases commence acutely, simulating the onset of a specific fever, and, from the fact that purpura is sometimes met with, the question has even been raised as to whether they are not in reality an abortive, fulminating form of small-pox. The bacteriology of the affection is by no means constant, as the pneumococcus has been found in the blood and the suprarenal glands in one case, while in others septic organisms were discovered. The cause of the hæmorrhage appears to be as varied as its pathology. Some cases are definitely connected with traumatism, while others are associated with gastro-intestinal disturbances. It has also been observed in the new-born and in certain diseases of the blood. All degrees of hæmorrhage are met with in the adrenals, from the minute, punctate spots to the condition in which the glands are converted into veritable "blood-sacs." In other instances, the medulla bears the brunt of the affection, the cortical portion remaining quite normal. The relation of suprarenal hæmorrhage to Addison's disease and to purpura is not yet settled, nor are the clinical signs definite enough to render a diagnosis of the condition possible during life.

Eruptions Simulating Scarlatina.

THE short article in last week's MEDICAL PRESS AND CIRCULAR on "Erythema Scarlatiniforme" was probably of interest to many of our readers, for we have had communications that certainly lead us to conclude that cases similar to those described by Kramsztyk have occurred, and have been reported on in this country. About ten years ago there was an epidemic in the West of London which led to Dr. Robert Lee addressing a letter to the Chairman of the Sanitary Committee of the Fulham Council on the subject; and this letter was published in the *British Medical Journal* in November, 1894. The *Lancet* published an article under the title, "Scarlet Fever and its Congeners" (October 13th, 1894), in which it was stated that Dr. Lee gave "an instructive description of some cases which recently happened in that parish (Fulham), and which simulated scarlet fever." Appended to Dr. Lee's communication was a letter from Sir Samuel Wilks, and another from Sir George Johnson, which show that the subject was of interest to them. On December 12th, 1896, in the *British Medical Journal*, Dr. Lee made a further report on these cases, and others that later came under his observation. In the second report Dr. Lee gives a full account of a malady which appears to be absolutely identical with that mentioned in our article on Kramsztyk's cases, and we think that precedence must be claimed for Dr. Lee in the observation and recording of such cases, and the distinct difference between them and true scarlatina. Dr. Lee's remark "that the whole subject of the pathology of eruptions is one, however, which requires more investigation than it has yet received," will be concurred in by many; and it is certainly one of very great interest to those who are required to diagnose and notify accurately, for as we concluded our article, "the diagnosis of scarlet fever is puzzling enough without this added terror lying in wait to catch one tripping." The irritation of the skin by bacterial action, direct or indirect, is a self-evident fact, and whatever the ultimate *causâ causans* may be, Dr. Lee's clinical instinct has detected a pathological relationship of considerable suggestive value.

(*a*) *Amer. Journ. Med. Sci.*, January, 1904.

Obstructive Self-Immolation.

THE brilliant discoveries of Dr. Manson and his co-workers in the domain of the prophylaxis of malarial fever are beginning to bear fruit, and the French Government has taken steps to enforce certain measures with the object of rendering several districts of Algeria less malarial. Active opposition has been offered to the execution of the decree by several Algerian practitioners on the ground that the conclusions arrived at by Dr. Manson and his school are erroneous and only apply, at most, to one or two comparatively insignificant forms of malarial fever. Drs. Treille and Legrain have enlisted the support of the medical practitioners of a Paris society, where a vote adverse to the new departure was carried unanimously. The most remarkable feature of the discussion is that these gentlemen, strong in their scepticism, demand that the experiment of communicating malaria by mosquito bites shall first be tried on themselves, and they solemnly undertake not to take quinine or other medicament which might jeopardise the success of the experiment. To make the offer more ridiculous the editor of a local newspaper, not a medical man, seeks to attain notoriety by insisting that he also must be experimented upon, and the Paris society actually endorsed these pretensions. Of course, the offer is only a feeble imitation of the experiment carried out by the Paris practitioner who attained brief notoriety by inoculating himself with bovine tuberculosis, and it is hardly necessary to point out that one or two observations on individuals would prove nothing either way in

view of the countless experiments upon which the present teaching is founded. It is as if a practitioner declined to make use of anti-diphtheria serum until he had contracted the disease and been cured thereby. The tribe of "antis" is evidently not limited to Great Britain.

The Supply of Poisonous Alkaloids by Chemists.

AN interesting trial has just been under consideration by the Paris tribunals. A watchmaker, who narrowly escaped death in consequence of the abuse of morphine and cocaine, brought an action to recover damages from five retail chemists, who, it is alleged, supplied him without hesitation with the toxic alkaloids in powder form as well as in solution for hypodermic injection. Now, under the French law, no chemist is entitled to dispense a poisonous substance except on medical prescription, with which the plaintiff was not provided. The defence was that the substances in question were not poisons within the meaning of the law, but the expert appointed by the court easily disposed of this contention. The tribunal was urged to decide against the defendants on the ground that by acting as they had done they rendered nugatory the precautions imposed by law in favour of the public. The judges have postponed their decision, the Pharmaceutical Syndicate having asked to be heard on behalf of the defendants, but it is to be hoped that no technical objection will be invoked to perpetuate a practice which is unquestionably in opposition to the public interest.

Typhoid Fever and Water Supply.

THE connection of typhoid epidemics with contaminated water supply is so well known that it seems almost superfluous to draw attention to yet another epidemic due to this cause. But the history of a recent outbreak at Lowell, Mass., is unusually interesting, since not only the source but the actual period of contamination are accurately ascertained. Lowell, which is a manufacturing town of about one hundred thousand inhabitants, is situated on the Merrimac River, and has a double water supply. One source, used only for industrial purposes, is drawn directly from the river, which a few miles up receives the sewage of Manchester. The other, for drinking purposes, and more recently laid on, is drawn from a system of driven wells, and is of good quality. There is no connection between the two systems except at one point, where, in case the river reservoirs should be exhausted by a sudden demand in case of fire, the well water has to supply the deficiency. The connection is guarded by "flapper" valves, which are supposed to prevent any flow from the river system to the other. On July 18th, 1903, a large fire occurred, and the valves opened. Some hours after the demand ceased, it was discovered that the valves were stuck open and that the river water was passing into the well water mains. Though immediate steps were taken to remedy the defect, a certain degree of admixture had taken place. Within a few days, a large number of cases of gastro-enteritis occurred in the districts supplied by the polluted mains. Within a few weeks typhoid fever made its appearance in the same districts, and whereas only four cases were reported in July, in August there were one hundred and thirty-six, and in September thirty-eight. No immediate bacterioscopic examination of the water was made, but ten days after the pollution took place *Bacillus coli* were found in the water. The epidemic emphasises again the moral that no caution is too great in guarding against an impure water supply.

The Therapeutics of Precious Stones.

PRECIOUS stones have at all times and among all peoples been reckoned among materials to be most carefully prized and safe-guarded. The gems of primitive races seem to have been at first valued for their supposed healing and protective virtues. Civilised people, on the other hand, have used them chiefly for purposes of personal adornment. Precious stones are chiefly distinguished by their transparency, lustre, hardness, colour, specific gravity, electric properties, refractive power, and symmetrical crystal form. The more important, arranged in their order of hardness, are diamond, ruby, sapphire, chrysoberyl, topaz, spinel, emerald, zircon, garnet, cordierite, tourmaline, quartz, chalcedony, opal, turquoise, nephrite, lapis-lazuli, malachite and amber. With the results of recent investigations into radio-activity and force-rays facing us, it is of interest to inqure if, after all, precious stones may not be capable of exerting therapeutic influence. Of one thing there can be little doubt, namely, that gems now as in the past, and as in all probability will be the case throughout the future, exercise a more or less marked action in initiating and maintaining emotional conditions and directing the play of psychological processes. The astute physician need not altogether neglect the part taken by gems in the kaleidoscopic variation of human sentiments, and the evolution of personal sympathies.

The Penalties of Malpraxis in Germany.

THERE is no country in Europe where the individual enjoys so much personal freedom as in England, and we are accustomed to regard this feature of our national life as one of the greatest of our birthrights. We trust it will be long, indeed, before the individual medical man in this country will be "cribb'd, cabin'd, and confined," as he is already in some countries on the Continent. For instance, in Germany, there is by law the severest punishment for inattention to certain more or less useful rules of practice. Among these we find that in case a medical man neglects to suture a ruptured perineum, he is liable to be mulcted by the courts to the tune of nine hundred marks (about forty-five pounds

sterling), to undergo three years' imprisonment, and to pay compensation to the patient. Now there is undoubtedly a universal consensus of gynæcological opinion in favour of immediate union of ruptured perineum, and though there may be few instances where it is advisable for the surgeon to adopt other than the customary procedure in regard to a particular lesion, yet the decision must lie with himself, and his responsibility should be to his patient, to the opinion of his professional brethren, and to his own conscience. It is obvious that, if interference by the State in the details of medical treatment be permitted in one instance, there is no logical limit to such compulsion, and whatever be the merits of democratic government, discernment and wisdom in medical treatment are not likely to be among them.

Life Insurance Examination Fees.

THE general tendency to cut down medical fees has long been a growing evil in professional life. In many ways medical men are themselves to blame, because they have set the example by placing their services at the disposal of the community on a scale of remuneration that is simply degrading. The evils of rivalry in an overcrowded profession are heightened by the competition of the hospitals, and by the incessant inroads of an ever-increasing army of unqualified practitioners and quacks, whom there is no law to restrain. Some of the less important life insurance offices are now reducing their fees to half a guinea. Is it too much to hope that medical men will stand by each other and refuse this reduction? As it is, a guinea is small enough remuneration for a highly skilled and responsible medical examination, including a report of the urine. Here in the United Kingdom the insurance offices have no difficulty in obtaining the services of men of the highest skill and absolute integrity at a fee of one guinea per examination. It will be an exceedingly unwise step on the part of the offices if they invite the entry of inferior men by a reduction of the scale of fees. In the United States rumour persistently maintains that insurance frauds are connected with this class of medical examinations in a way that we are happy to think is practically non-existent among British practitioners.

The Hygiene of the Door-Ma .

UNTIL the time comes when street-mud shall be no more, so long will the door-mat continue to be a household necessity. The thoughtless individual who omits to remove the superfluous dirt from his foot-gear in the manner that custom has dictated is the terror of the careful housewife and an unconscious object of execration on the part of the domestics. We are not aware that a bacteriological examination of the dried mud obtained from a door-mat has been specially made, but from the sanitary point of view there is no doubt that this article is quite as often a cause as a preventive of disease. Cases of lead-poisoning have been traced to the dissemination of fine metallic particles emanating from the mat after long-continued friction against the boots of a pottery-worker, and this among persons in whom it was shown that infection from every other source was precluded. Tubercle and tetanus bacilli, to say nothing of the bowel-organisms of the horse, would be found in the dust thus harboured, coming, as it does, from road soil where it is known that these organisms flourish. There is one particularly objectionable practice unavoidably connected with the use of door-mats, namely, their beating or shaking in the front precincts of the house or upon the public highway. The unwholesome clouds of dust thus raised often settle again in the hall or passage, or are blown into rooms through the open windows. A worse nuisance is created when the only available space for shaking is the pavement, especially in the early morning during the busy hours of passenger traffic. Many of the Metropolitan boroughs have recognised the danger of this unwholesome practice, and have prohibited the beating of door-mats after a specified time in the morning. For the infringement of this by-law a fine of five shillings has been recently imposed at the Thames Police Court, and it would be well if the law regarding the matter were more rigorously enforced.

The Silent Operator.

THE surgeon of the future, if he is to keep in touch with the findings of bacteriology, will indeed be a strange creature. He is already clad in sterilised garments, and has his hands sterilised by minute and formal ablutions. Some operators work in sterilised gloves. Others cover their heads with caps and their beards with bags, in order to prevent the chance falling of bacteria from these hairy lurking places upon the wound. Now an Amsterdam surgeon comes along and says that every time we speak we unconsciously emit a huge spray of saliva which is charged with the harmful micro-organisms that are found in enormous numbers in every human mouth, healthy or otherwise. He more than suggests that some of the mysterious bad results of modern operative surgery may be explained in that way. The truth of his conclusions was proved experimentally by talking into a box containing prepared plates from which numerous colonies of bacteria were afterwards cultivated. Every surgeon, even the most taciturn, speaks 150 to 200 words in the course of a short operation, lasting, say, a quarter of an hour. Other surgeons, again, talk incessantly right through an operation. It would be almost impossible for a surgeon to avoid speaking during an operation. The suggested remedy is to wear a sort of cotton wool respirator which permits of audible speaking, but filters off the bacteria. At the same time, it is only fair to add that many talking surgeons have achieved a fine record of success in their operative work.

PERSONAL.

DR. JAMES MILWARD, who has been in the Poor-law Medical Service since the year 1867, has resigned his position as Medical Officer to the east district of the Cardiff Union.

DR. W. JAPP SINCLAIR, Professor of Obstetrics and Gynæcology in Owens College, Manchester, has been elected President of the North of England Obstetrical and Gynæcological Society.

DR. JAS. BARR, Physician to the Liverpool Royal Infirmary, Lecturer on Clinical Medicine in Liverpool University, has been elected President of the Liverpool Medical Institution for the current year.

ON January 21st, the Lord Rector of the University of Edinburgh, the Right Hon. Sir Robert Finlay, M.P., delivered an address to the students of the University in the M'Ewan Hall in his capacity of Lord Rector of the University.

DR. JOHN HAY, formerly Assistant Physician to the Stanley Hospital, Liverpool, has been appointed one of the Physicians of the hospital, in succession to Dr. J. Lloyd Roberts, who has been elected to a similar position at the Royal Southern Hospital.

PROFESSOR ROBERT B. WILD'S important address on "University Education for Pharmacists" appears in the current number of the *Pharmaceutical Journal*, and should receive the attention of all interested in the evolution of the pharmacist-graduate.

THE Earl of Derby, K.G., as Chancellor of the University of Liverpool, a few days ago headed a deputation to the City Council, which, in reply, granted a sum of £10,000 to the University during the year 1904, such sum to be paid out of the city rate.

ON Thursday, January 7th, a bronze statue of heroic size was unveiled of the late Hunter Holmes McGuire in the Capital Square, Richmond, Virginia, the Legislature of the Commonwealth having passed a Bill authorising its being placed there, in close proximity to that of his beloved leader, Stonewall Jackson.

THE Gloucestershire County Council has appointed Dr. J. Middleton Martin, the County Medical Officer of Health and the Medical Officer of Health of the Stroud district, Executive Officer under the Midwives Act at a salary of £105 per annum and out-of-pocket expenses.

DR. ARGYLL-RORERTSON will shortly leave Edinburgh to reside in Jersey. He was appointed Lecturer in Ophthalmic Surgery in the Edinburgh Royal Infirmary in 1890, about the period when he published his famous researches in the eye conditions in various nerve disease, notably the "Argyll-Robertson" pupil in locomotor ataxy. He graduated at St. Andrews in 1857. He has always been a notable athlete, and is a member of the Royal Bodyguard of Scottish Archers.

Cremation Statistics.

IN his report to the Municipal Council of Paris M. Ranvier states that there are twenty-eight crematoria in Italy, six in the United States, nine in Great Britain, eight in Germany, four in Switzerland, three in France, (Paris, Rheims, Rouen), and two in Sweden, while Denmark, Canada, Argentina, and Australia each possess one. France occupies the first place in the matter of cremations. From August, 1889, to the end of 1901 27,171 bodies of persons who had died in the hospitals, 2,399 private individuals, and 20,178 stillborn children were cremated. The United States comes next, with 15,986 cremations.

A MEDICAL MARTYR.

THE LATE DR. W. J. CONEYS, OF ROUNDSTONE.

IT is with deep regret that we announce the death of Dr. W. J. Coneys, medical officer of Roundstone dispensary district, Clifden No. 1 Union. This great area is worked by two medical officers, whose physical strength is taxed to the utmost in their attempts to fulfil their duties among a very poor population, the majority of whom have no idea of cleanliness, who believe that "muck is luck," and whose cabins are foci of dirt diseases. Amid such surroundings Dr. Coneys worked, and fearlessly encountered all risks. But he, no more than any other medical officer, was immune to that dreadful fever, the fear of which in the west, where it is so common, parts wife from husband and mother from child. It became Dr. Coneys' duty to visit typhus in one of those wretched hovels, in which escape from infection is impossible, and the duty was heroically undertaken and his life given for his patient.

A few days before his death he wrote to Dr. Kinkead, of Galway, a description of the duties he had to perform in this case—duties, be it noted, not obligatory to his office, but solely imposed upon him by feelings of humanity. His patient died, and, in his own words, "I could not get a man for love, whisky, or money, to help me, and I was obliged to coffin the corpse, along with the nurses and another." Dr. Coneys' sad death, following, as it does, on those of Dr. Kean, of Arran, and Dr. Conroy, of Spiddal—three deaths within three years in the county Galway alone—shows full well that great as are at times the dangers associated with a soldier's life, the dangers which surround the medical soldier, who fights disease and death, are still greater. Who can deny that the bravery shown is also greater far? There are thousands of men who will face death bravely when spurred on by the surroundings of the moment and the glamour that will always surround physical courage, but the number of men who will in cold blood shake hands with death, when it presents its dread form shorn of the trappings that serve to hide it from the excited brain, are but few, and many of them, we are glad to think, are found in the ranks of the medical profession. The question will arise, Why is it that men voluntarily undertake such risks? If they safely pass through the danger no one wots of its existence, and the thanks they receive are small. If they fall victims to their generous actions, a momentary enthusiasm is created, men congratulate one another that the world still possesses silent heroes, and that is all. No bonds of official duty can compel a man to actions such as those of Dr. Coneys and his assisting nurses, but when the silent calls of humanity hint that there is work to be done, there are few members of the medical profession, and, we are glad to think, still fewer members of the Irish Poor-law Medical Service, who do not respond. When will the public at large understand that what humanity in the abstract demands must be paid for by humanity in the concrete? Is it right, is it honest, to call for a man to take up duties such as those of the Poor-law Medical Service, duties which never end in glory, though they may often lead to the grave, only to reward him for the discharge of those duties by a miserable pittance, to refuse him the means of recovering his health from time to time, and often to leave after his death his immediate relatives in poverty? Medical men, like their fellows, have their duty to humanity to discharge, and humanity has its duties to discharge to medical men. It may seem a useless sacrifice that a living man should lose his life in order that a dead one may be buried, but such deeds serve to show to each one his duties. It may even be that they may also serve to bring out of its present seclusion into prominence that other duty to which we have referred—the duty of humanity to medical men.

Special Correspondence.

(FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

SPREAD OF SMALL-POX.—Small-pox still continues to spread in Scotland, and scarce a day passes without a case being reported in some new locality. In Glasgow on the 21st inst., there were under treatment 235 cases, the death-roll up to that date being 36. In the Coatbridge district 27 cases have broken out. A case has also been found in a lodging-house in Leith, and there the corporation took the wise step of offering 2s. 6d. to every inmate of a common lodging-house who would submit to be vaccinated. Several cases of the disease have also occurred in Edinburgh, one in the person of a Christian Scientist, who seems to have been visiting among the sick in Glasgow. He had had the disease on him for several days before being admitted to hospital, and, unfortunately, succumbed to it. The disease has also broken out in the navvy huts in connection with the construction of the Ayr and Girvan Railway, in Hamilton, in Perthshire, in Lochgelly, in Upper Renfrewshire, and in Cambuslang, Govan, Greenock, and Paisley.

EDINBURGH UNIVERSITY RECTORIAL ADDRESS.—Sir Robert Finlay, Lord Rector of the University, delivered (or attempted to deliver, for the students took good care that no single sentence of it should be audible) his Rectorial Address in the MacEwan Hall, on the 21st inst., his subject being International Arbitration. The undergraduates behaved exceedingly badly, their conduct recalling the very worst days of the era which all had hoped was ended with the birth of the Students' Representative Council. Apparently, however, the body has lost the respect of the students, or is, at least, quite incapable of dealing with such an organised exhibition of vulgar rowdyism as disgraced Thursday's meeting. Great latitude is allowed to the students on the occasion of the Rectorial Address, but their conduct on this occasion has met with universal reprobation. It is sincerely to be hoped that the Students' Representative Council, or the Senatus, will offer some apology to Sir Robert Finlay and to the Chancellor, Mr. A. J. Balfour, for the discourtesy, amounting at one part of the procedings to deliberate insult, which was shown them, and also to the people of Edinburgh for the discredit which such behaviour casts on the city. It is very generally felt that scenes like those of Thursday will make it difficult for the students to get any respectable man to occupy the post of Lord Rector, and they will certainly close the purse-strings of many who would otherwise have felt disposed to respond generously to an appeal for funds to extend the University Union which was issued broadcast only a few days before the Rectorial Address.

EDINBURGH ROYAL INFIRMARY.—The question of an age-limit, to which reference was made last week, and which was supposed to have been definitely settled by the managers, was again thrown into the melting-pot by the action of the Court of Contributors at the adjourned meeting on the 18th inst. It will be remembered that at an earlier meeting a motion extending the operation of the age-limit to the Professors holding wards was carried, while the committee of Contributors recommended to the adjourned meeting that the whole matter should be delayed. Accordingly a motion delaying approval of the new rule (*i.e.*, an age-limit for ordinary physicians and surgeons only) and remitting to a committee of the Contributors and Managers for consideration and report was carried. It will be a thousand pities if so excellent a principle as the age limit be departed from, and we sincerely hope that some agreement will be arrived at for the impartial application of the rule.

BELFAST.

THE PROPOSED CONSUMPTION SANATORIUM AT WHITEABBEY.—The proposed purchase of the Abbey, a large old country house about five miles from Belfast, on the north shore of Belfast Lough, is being vigorously protested against. At a public meeting in Whiteabbey, most of the leading residents of the neighbourhood were present. They protested on the grounds that the site was unsuitable for the purpose, being a cold clay soil, that the cost of adapting the old building to its new purpose would be so great as to add largely to the rates, and that the close proximity of the house and grounds to a large manufacturing village such as Whiteabbey is, would be a source of danger to the latter. A Local Government Board inquiry into the proposed scheme was held in Belfast last week, and at this inquiry the objectors to the scheme were strongly represented. The lands of the Abbey extend to 33 acres, and would accommodate 150 to 200 patients in huts, according to Dr. Richard Purdon, one of the physicians to the Forster Green Sanatorium, who expressed general approval of the scheme. The soil is said to be 12 to 14 inches in depth, and under it is a red retentive clay mixed with gravel. It was said that there would be no difficulty in draining it properly, but there seems little doubt that at present it is decidedly damp. Dr. McKisack, a visiting physician to the Royal Victoria Hospital, said that he had inspected the grounds and found rushes growing on the lawn, and that when he stepped from the raised avenue to the ground below he found he was walking in surface water. In two places he excavated and found red retentive clay in one at six and the other ten inches from the surface. He was of opinion that the site was most unsuitable and unhealthy for consumptives. Dr. Manley, a local practitioner, was also strongly opposed to the site, believing it to be too damp and relaxing. On the whole, the weight of medical opinion is decidedly against the scheme, but it remains to be seen what decision the Local Government Board will come to in the matter.

SMALL-POX IN BELFAST.—As predicted n this column a fortnight ago, there has been a decided increase in the number of small-pox cases. It was mentioned then that a child had been found in a crowded house in a very poor locality. The parents of that child and an old woman who nursed her have since developed the disease, and fresh cases are now occurring daily. Some of these are cases which have a clear history of having been in contact with previous cases, but others are now coming in from almost all parts of the city, showing that the infection is widely diffused.

Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

"KOPLIK'S SPOTS IN MEASLES."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an article under this heading in your issue for January 20th, 1904, you observe:—"The early diagnosis of measles, then, is a great *desideratum*. It seems curious in this connection that the lesions of the buccal mucous membrane known as Koplik's (not 'Köplik') spots should not have received wider recognition than has been accorded to them. These spots were first definitely described by Filatow in 1895, although it is possible that Flindt may have indicated the same changes in his paper published in 1880. The subject was not taken up till 1896, when Koplik, of New York, wrote, in the 'Archives of Pediatrics' an account of them which differed somewhat from that of Filatow, but was undoubtedly intended to apply to the same lesions. At all events, Koplik's name came to be associated with the discovery."

It appears to me that Koplik's "discovery" is nothing new. All close observers of measles for generations have recognised the fact that the rash of the disease shows itself as early as the second day of invasion on the palate and buccal mucous membrane. "Koplik's spots" are the papules of measles modified by their situation on a mucous membrane. Writing in 1891, five years before Koplik's "discovery," I

quoted Dr. Hilton Fagge on this point. Describing the stage of invasion of measles, I wrote as follows:—"On the second day an *efflorescence* may spread over the skin, leading to a wrong diagnosis of scarlatina. This accidental rash may also simulate urticaria because of the itchiness which accompanies it. It is, doubtless, erythematous in character. About this time, further, according to Dr. Hilton Fagge, an eruption of scattered points and spots may be seen over the mucous membrane of the soft palate."—"Eruptive and Continued Fevers." Dublin: Fannin and Co. 1892. Page 138.

In his monograph on "Measles" in the second volume of the English edition of Von Ziemssen's "Cyclopædia of the Practice of Medicine," published in 1875 (twenty-one years before Koplik's "discovery"), Thomas, of Leipzig, gives a detailed account of the appearances described by Filatow and Koplik, as he observed them on the palatal mucous membrane, the buccal mucous membrane, and the conjunctiva. While Thomas does not recognise the perfect justice of the term "exanthem of the mucous membrane," he willingly concedes that, since the peculiarities of the process upon the mucous membrane are unmistakable, one does not need to be so precise in one's application of the conception of the exanthem of measles here as upon the outer skin, since not its form, but its mere appearance at all, is of any significance in regard to a diagnosis.

I am, Sir, yours truly,
JOHN WM. MOORE, M.D.Dub., F.R.C.P.I.

ALOPECIA AND DENTAL CARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—M. L. Jacquet's observations, upon which you comment in your issue of January 20th, are interesting to dental pathologists and dental surgeons. It must be always borne in mind that, once calcified, the hard tissues of the teeth—enamel and dentine—are physiologically unalterable; they can be affected only by external agents. The main predisposing cause of caries is formed by innate structural defects, especially in the enamel. Few sets of teeth in civilised man are to be discovered absolutely free from inherent weaknesses, whilst in great numbers the enamel and dentine show large areas of ill-formed tissue in many, if not all, of the members. The onset and progress of caries are governed mainly by defects of the tissues, the other chief cause being vitiation of the secretions due to neglect or disease by which acid fermentation in the *débris* lodging upon the teeth is encouraged. That caries is especially noticeable in circumstances suggestive of correlation with alopecia is certainly not my experience, nor, so far as published writings go, is it the experience of dental pathologists. Degenerate hair is not a constant accompaniment of degenerate teeth, albeit they are equally dermal appendages, and, presumably, subject to similar hypoplastic influences during development. If a patient's powers of mastication are seriously interfered with by dental caries his physiological apparatus becomes so far handicapped, and if other factors exist it is possible this may lead to a state of general malnutrition. Such debility might no doubt show itself locally in the hair follicles with resulting alopecia, and in such a case caries would certainly constitute a contributory cause; so that in some instances there might be traced between these diseases a connection hardly less close than M. Jacquet suggests, although not quite of the same kind.

I am, Sir, yours truly,
M.R.C.S., L.D.S.

January 22nd, 1904.

THE HOME OFFICE AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to your comment on my previous letter, I wish to state that at one time the Home Office appears to have treated the medical profession with more deference (as regards one class of cases to which I referred) than it does now. In support of this statement I shall quote the terms of a free pardon granted to one Edward M'Quirk, in the year 1769, from the *Annual Register* of that year. M'Quirk had given a man named Clarke a blow, apparently unprovoked, during an election riot, and the main question was whether Clarke had died of the blow (I omit M'Quirk's aliases):—

"Whereas a doubt has arisen in our Royal breast concerning the evidence of the death of George Clarke, from the representations of Wm. Bromfield, Esq., surgeon, and Solomon Starling, apothecary, both of whom, as it has been represented to us attended the deceased before his death and expressed their opinions that he did not die of the blow he received at Brentford: and whereas it appears to us that neither of the said persons were produced as witnesses upon the trial, though the said Solomon Starling had been examined before the Coroner, and the only person called to prove that the death of the said George Clarke was occasioned by the said blow was John Foot, surgeon, who swore that he never saw the deceased until after his death, we thought it fit to refer the said representations, together with the report of the Recorder of our City of London of the evidence given by Richard and William Beale and the said John Foot at the trial of the said Edward M'Quirk for the murder of the said Clarke, to the master wardens and the rest of the examiners of the Surgeons' Company, commanding them likewise to take such further examination of the said persons so representing and of the said John Foot as they might think necessary, together with the premisses above-mentioned, to form and report to us their opinion whether it did or did not appear to them that the said George Clarke died in consequence of the blow which he received in the riot at Brentford on the 8th of December last. And the said Court of Examiners of the Surgeons' Company having thereupon reported to us their opinion that it did not appear to them that he did, we have thought it proper to extend our Royal mercy to him, the said Edward M'Quirk, and to grant him our free pardon for the murder of the said George Clarke, of which he has been found guilty."

Now compare this with, for instance, the well-known Maybrick case. In that case the Home Secretary is known to have taken the opinions of several medical gentlemen, but the names of those consulted and the manner in which they were divided in opinion has never been published. Further, we do not know what statement of the evidence was laid before them and whether any new facts were communicated to the Home Office as to Mr. Maybrick's habit of dosing himself or of the causes to which he himself ascribed his illness were laid before them. But perhaps the most important difference is that the Home Secretary did not consult any representative medical body or empower them to put questions to the medical witnesses which might have tended to bring out the relevant facts much more clearly than the questions put to them by counsel. In a case of this kind the weight of medical opinion received by the Home Office might very probably depend altogether on the official who selected the doctors to be consulted. The improvising of a medical Court of Appeal by the Home Secretary for the occasion is as objectionable as the improvising of a legal Court of Appeal or a Police Court of Appeal—though any of these might possibly do better than the officials if left to themselves.

I am, Sir, yours truly,
A BARRISTER.

[The moral and circumstantial, apart from the scientific, evidence in Mrs. Maybrick's case was overwhelming. The wife's intrigue, the quarrels, the purchase of the poison, the finding of arsenical papers in the bedroom, and other facts pointed to an absolutely clear conclusion.—ED.]

THE MISSING LINK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask from any of your correspondents, so much prejudice and incredulity existing in the public mind, and more especially the clerical portion, as to the truth or otherwise of man's evolution from a lower type of animal on account of the great intellectual gap between the two—whether the idea of the origin of language (I use "language" in its broadest sense, *i.e.*, hieroglyphic or phonetic) has been advanced to account for this?

It must appear, I submit, fairly evident that language in its earliest dawn, or rudimentary stage, would or might commence so complete a change in the environment of sentient existence, owing to the creation of a medium for interchange of ideas, as in the process of time sufficiently to account for the intellectual breach between man and the anthropoids. I shall be glad, therefore, if you will allow me to submit to your readers the following considerations:—

1. It must be self-evident that the art of language did at some epoch more or less remote have a beginning, and this independent of the hypothesis whether man has from all time been a distinct and separate species.

2. It may, I think, be fairly surmised that in the most remote period of man's history, assuming him from the first a distinct species, that there need not necessarily be at the period in question any considerable degree of intellectual difference between man and a lower animal, because the means of exercising, developing, and consummating the faculties are not sufficiently advanced or properly in vogue.

3. Assuming the correctness of this surmise, it seems reasonable to suppose that the improvement between man's intellect at the present compared to his first appearance in Creation can only find its equivalent in the development of language.

4. I have already surmised that the mental faculties of man at his most remote period need not far exceed that of a lower animal; hence it would seem that the intellectual gap in *man's individual history* may be equal to the gap which now exists between man and the anthropoids.

I should be glad, therefore, to ascertain if any of your correspondents think these considerations worthy of notice, or if they carry any weight, as it appears to me that so far from the breach in intellect being a point against Darwin's theory, it is what one should expect.

I am, Sir, yours truly,

CLEMENT H. SERS.

Preston Drove, Brighton, Jan. 22nd, 1904.

DOCTORS *v.* BARRISTERS AND SOLICITORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have often wondered why medicals are such fools in giving so much service for nothing, and in accepting as a working basis the idea that it is better "to throw a sprat to catch a mackerel" than to act in an honest businesslike way. The above views are revived by studying the Midwives Act, in which no provision whatsoever has been made for paying medicals called in; and by looking into the Poor Prisoners' Defence Act, 1903, in which Parliament has enacted as follows:—

"Section I. (1) When it appears, having regard to the nature of the defence set up by any poor prisoner . . . . that it is desirable, in the interests of justice that he should have legal aid in the preparation and conduct of his defence and that his means are insufficient to enable him to obtain such aid," the Justices, or the Judge, or the Chairman of Quarter Sessions, "may certify that the prisoner ought to have such legal aid, and thereupon the prisoner shall be entitled to have solicitor and counsel assigned to him."

Under the above Act the Secretary of State has issued the following rules:—Solicitor's fee, from £2 2s. to £5; travelling expenses (for self and clerk); counsel's fee, £1 3s. 6d. to £3 5s. 6d.

Now, Sir, we must congratulate our legal brethren for having such an Act passed. Each year the legal profession is making itself more and more felt in public importance; while the doctors—well, they can sue persons for using certain medical "titles," and allow a Midwives Act to pass without a single proviso such as is in the Poor Prisoners' Defence Act. It has been stated that about £1,000,000 per annum will be required to cover the fees under this Act. Let every medical obtain a copy, and make a close study of it. Then perhaps—I use the word perhaps—they will lay aside their petty jealousies, in tongue and backbiting, and work as men entitled to payment for services. Doctors evidently prefer "to take their licking lying down."

I am, Sir, yours truly,

ROBERT R. RENTOUL.

Liverpool.

ERYTHEMA SCARLATINIFORME.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your article on "Erythema Scarlatiniforme Desquamativum Recidivans," you make the remark that, "There has been but little attention paid to desquamative erythema in this country, and probably most medical men have not met with instances of it in their practice." May I direct your attention to a communication I made to the *British Medical Journal* in November, 1894, and to an article in the *Lancet*, "Scarlet Fever and its Congeners," October 13th, 1894; and to another communication to the *British Medical Journal*, December 12th, 1896? Copies of the two last I send you. The question of pathological interest in such cases is the depth to which the skin is affected. Why the skin should peel in some cases and only effloresce in others is an interesting one. I am glad to see that some attention is being given to this subject, though I am sorry that we wait till it comes from Germany or some other source.

You conclude your article: "It is well, however, to be on one's guard, for the diagnosis of scarlet fever is puzzling enough without this added terror lying in wait to catch one tripping"; and this confirms the opinion expressed at the end of my communication to the *British Medical Journal*: "The chief point, however, to which we ought to give attention is to be careful not to mistake this malady for either diphtheria or scarlatina, as is very liable to be done."

I am Sir, yours truly,

ROBERT LEE.

West Kensington, Jan. 21st, 1904.

[Dr. Lee's claim to originality in the interesting condition alluded to appears to rest on a solid basis. We hope to publish a short *résumé* of his work on the subject.—ED.]

ST. BARTHOLOMEW'S HOSPITAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The number of beds which the Governors wish to accommodate on the 6¼ acres available in Smithfield is about 700, at about 45 square yards per bed, whereas 100 square yards per bed is the minimum laid down by recognised authorities.

In order to contrast the value of the Governors' scheme for rebuilding on the Smithfield site with that of the alternative scheme for the suggested removal to the suburbs, the following figures will prove convincing:—

St. Bartholomew's Scheme.—The value of the 6¼ acres at present owned by the Hospital, based on the rate at which the adjoining land has lately been acquired by the General Post Office, is approximately £1,040,000.

The total cost of rebuilding on the present site, so far as can be ascertained at the present time, would be at least £500,000 for the buildings and £240,000 for the land recently acquired, making an estimated total of £740,000.

Alternative Scheme.—A perfectly equipped hospital for 700 beds, providing the necessary 100 square yards per patient, could be erected in a suitable position in the suburbs for £675,000, including the cost of land. This outlay would be met by the sale of the land in Smithfield, amounting to over a million sterling, and would leave a balance in the hands of the Governors

amounting to about £365,000, which, if properly invested at 4 per cent. would increase the revenue of the hospital by about £15,000 per annum.

It is not too late for Sir Trevor Lawrence to justify the action of the Governors in invoking such a powerful influence as the Mansion House Fund in support of their appeal for £500,000, which must have the effect of crushing the urgent appeals of poorer, if not more deserving, hospitals.

I am, Sir, yours truly,
ALBERT W. MOORE.

85, Gresham Street, London, E.C.

[The foregoing letter is reproduced from the *Daily News* of January 25th. It so strongly confirms our attitude with regard to "partial removal" that we print it *in extenso*.—ED.]

BRITISH MEDICAL ASSOCIATION REPRESENTATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your leading article which appeared in THE MEDICAL PRESS AND CIRCULAR o January 20th, I would point out that the British Medical Association has not formulated a demand for direct representation on the General Medical Council.

At the annual representative meeting held at Swansea last year a resolution was passed by the representative meeting: "That a petition be presented to the Privy Council praying that in any future legislation the British Medical Association be directly represented on the General Medical Council in proportion to its magnitude and representative character."

This resolution was passed for reference to the divisions for their consideration.

It remains to be seen what the decision of the divisions will be, and pending such information the British Medical Association has not moved in the direction you would imply.

I am, Sir, yours truly,
(Signed) GUY ELLISTON,
General Secretary.

The British Medical Association,
429 Strand, W.C.

Literature.

VINCENT'S NUTRITION OF THE INFANT. (a)

THE literature of infant feeding grows apace. The importance of the subject cannot be over-estimated, and we feel certain that it is impossible to write too much regarding it. Consequently we hail the present work with satisfaction as it is an addition to our already too scanty knowledge of the management of infant life. The book is the outcome of the author's personal dissatisfaction with the modes of infant feeding in vogue in this country. The work has as its basis the researches of Rotch, than whom there is no greater living authority on the subject.

The opening chapter deals with the composition of human colostrum and milk. With regard to colostrum the author maintains that no great advantage is to be gained from the ingestion of colostrum, and states that many of the disturbances of digestion during the first week of life are due to the excessive amount present in the mother's milk. He states later on (p. 37) that it is a serious mistake to allow the infant to take freely of the colostrum when this is plentiful. The chemical composition of colostrum indicates that anything but a small amount seriously disturbs the infant. The author's experience does not uphold the ordinary view that early suckling aids and stimulates uterine contraction.

In dealing with the complications of lactation the writer refers to a condition which he has termed lymphangitis mammæ, in which we have an inflammatory condition of the superficial structures of the gland. It is an alarming condition, but readily yields to hot fomentations and active purgation. We are pleased to note that, in speaking of the care of the breasts during pregnancy, Dr. Vincent absolutely warns against the use of spirituous applications, which tend to cause fissures and excoriations. In this connection he refers to his own "Pregnancy Corset Belt" as being not only supporting but allowing for freedom of movement at the same time. He does not appear to favour mixed feeding in those cases where the milk supply is deficient. "In the interests of the mother it is unfair to advise her to continue nursing when evidence of the stress is present." (P. 53.)

In speaking of infant feeding by other means than that of mother's milk, the author very wisely distinguishes between what he calls "substitute" and "artificial" feeding. The former he regards as the method "by which the infant is supplied with milk from another woman, or from some other animal after modification to adapt it to the infant's digestion," the latter he defines as the mode "by which an infant is fed on preparations artificially manufactured from milk or from other products." A very interesting account is given of the laboratory methods of modifying milk in accordance with physicians' prescriptions of which a number of typical examples are supplied in the text. Artificial feeding is condemned, and the bulk of the various foods on the market are strongly depreciated. The great evil they one and all possess is their "facility for use." (P. 116.) They are also readily digested, but this is largely due to their containing so small an amount of food material. Their danger lies in the fact that disorders arising from imperfect feeding escape for a long time the notice of the parent. Such children are pallid, flabby, and listless. In other words they lack resistance against disease. The author has struck the right note here, and the sooner the profession at large realises the facts the better. The market is flooded with infants' foods, all more or less calculated to produce rickets, and other nutrition diseases, and the banishment of them from our nurseries would be an incalculable gain to the developing race.

The chapter on the heating of milk is pregnant with important facts. As Dr. Vincent points out, the prime object to be aimed at is a pure milk supply, for "milk containing pathogenic bacteria is contaminated, whether heated or unheated." (P. 132.) The objections to milk sterilisation are carefully detailed, and no one who gives this matter attention can fail to be impressed by the fact that what we want is not a sterilised milk supply at second hand, but one which is absolutely pure as drawn from the cow. This means careful feeding and housing as well as cleanly manipulation of the milk both while being drawn off and during its storage and transport.

The later chapters in the book treat of the chemistry of infantile digestion, the normal development of the infant and nutrition disorders, including rickets and scurvy. The concluding chapter gives a brief but striking account of infantile mortality as shown by the registrar's report for various large English towns. On page 286 we find the following noteworthy sentence, which we quote for the benefit of our readers: "Hospitals for the treatment of diseases of nutrition in infants need to be established in every large town or district." We heartily add our assent to these important words, and trust the day may soon come when such institutions will be an established fact.

We have read this work with pleasure and not a little profit. It covers the ground in a very interesting and yet comprehensive manner. The author's style is clear and instructive, while the numerous tables supplied will be found useful for reference, many of them, indeed, being quite inaccessible save to those who are familiar with German. The subject of infant feeding has not as yet received the attention it deserves in this country, and, accordingly we welcome this book from the pen of an English physician all the more eagerly. It deserves to be widely read by general practitioners as well as by those who make pediatrics their special study.

(a) "The Nutrition of the Infant." By Ralph Vincent, M.D., M.R.C.P., Physician to the Infants' Hospital, late Senior Resident Medical Officer, Queen Charlotte's Lying-in Hospital. Pp. 313, with 3 Illustrations. Demy 8vo, 10s. 6d. net. London: Bailliere, Tindall and Cox. 1904.

TOLDT ON HUMAN ANATOMY. (a)

WE have received the first volume of the English translation of this fine work, and are greatly pleased with the manner in which it has been reproduced. The original is a work of much value, and one which will well repay the cost of translation. Dr. Paul, who is responsible for this difficult task, has succeeded admirably, and may be said to be among the few translators who have made additions to the original without impairing the value of the book. His additions are of considerable value, especially to those who are not skilled in foreign nomenclature. As is well known, in many instances foreign nomenclature differs to a marked extent and in a very confusing manner from English nomenclature, and the translator has overcome this difficulty by placing the English term and its foreign equivalent side by side. For this reason, the book is not only an Atlas but a glossary of anatomical terms and their equivalents.

The drawing of the different bones is admirable, and leaves little to be desired save in a few instances, where a larger drawing might have been of more value, It is intended to publish the Atlas in six sections, of which the book before us is the first. If no unforeseen delay occurred, it was intended to complete the issue within the year, but as only one further instalment has so far reached us, we fear that the inevitable printer's delay has occurred. We can cordially recommend the Atlas to both students and medical men.

Obituary.

FRANKLEN GEORGE EVANS, M.R.C.S., ENG., L.S.A.

WE regret to announce the death of Mr. Franklen George Evans, on January 17th, after an attack of apoplexy in his seventy-seventh year. Deceased was the son of Edward Evans, at one time the only surgeon in Cardiff, when the population was numbered only by a few thousands. Mr. Evans received his medical education at St. Bartholomew's Hospital, and in 1849 qualified as M.R.C.S.Eng., and L.S.A. After being house surgeon to the Cardiff Infirmary, he was appointed surgeon to the Pentyrch Colliery and Ironworks, and to the Melingriffith Tinplate Works. Mr. Evans was at the time of his death chairman of the Rhymney Railway Company and a director of the Pontypridd Waterworks Company, as well as of many other large industrial concerns. Much of his spare time was devoted to the study of astronomy, and he was a Fellow of the Royal Astronomical Society. A few years ago he presented to the Cardiff Corporation a large and valuable astronomical telescope. Mr. Evans was twice married, his second wife being a grandniece of Mrs. Wyndham Lewis, who subsequently became the Countess of Beaconsfield. He retired from active practice twenty years ago.

MR. JONATHAN WILLIAMS, J.P.

THE death is announced of Mr. Jonathan Williams, J.P., of Bargoed, at the age of 66. Deceased had been engaged in practice at Bargoed for the last 30 years. He was chairman of the first Parish Council for Gelligaer, and in 1894 was placed on the Commission of the Peace for the Caerphilly Lower Division. The deceased gentleman owned a colliery at Bargoed, he was a director of the Rhymney and Aber Valleys Gas and Water Company, and chairman of the Income Tax Commissioners for the district. He leaves behind a wide circle of friends and acquaintances.

Beri-Beri at Lorenzo.

NEWS from Lorenzo Marques states that several cases of beri-beri have broken out there, seventeen negroes and three white people having already died from the terrible plague.

(a) "An Atlas of Human Anatomy for Students and Physicians." By Carl Toldt, M.D., Professor of Anatomy in the University of Vienna; assisted by Alois Dalla Rosa, M.D. Translated from the Third German Edition by M. Eden Paul, M.D.Brux., M.R.C.S.Eng., L.R.C.P.Lond. First Section: A. The Regions of the Human Body; B. Osteology. Figs. 1 to 377, and Index. London: Rebman, Ltd. 1903. Pp. 160.

Laboratory Notes.

CADBURY'S COCOA ESSENCE.

IT is many years since we analysed the various cocoas then before the public, and we think it desirable for the public health to ascertain from time to time in the laboratory whether manufacturers are keeping up to original standards. To this end we have submitted samples of this well-known cocoa to a careful analysis, with the following results:—

Moisture, 3·4; nitrogen, 3·25; albuminoids, 20·31; inorganic salts, 4·4; cold water extract, 18·4; and cocoa butter.

The inorganic salts, amounting to 4·4 per cent. on treatment with water, yields 1·4 per cent. of soluble ash, and 30 per cent. of insoluble matter. This latter contained the due proportion of alkaline salts that are found in pure cocoa that has not undergone any treatment with chemicals. The cold-water extract, 18·4, is sufficient evidence that no soluble diluent, such as sugar, has been added, and the microscopical examination proved the absence of foreign starch, which is so often added in enormous quantities in cheap cocoa. The cocoa-butter (*oleum theobromatis*) is present in due proportion. The natural bean contains something like 50 per cent. of cocoa-butter, and this quantity is too great to enable cocoa to be presented in a powdered form in the process of manufacture, therefore a part of this is removed by pressing the beans heated to a suitable temperature, and this method is much more to be commended than that of adding diluents, such as starch, sugar, or dried albuminoids from milk. The figures obtained agree well with the "Standards of Purity in Food and Drugs," recently published by Mr. C. G. Moor, M.A., F.I.C., and the aroma and flavour leave nothing to be desired.

We have pleasure in laying before our readers the foregoing evidence that the cocoa essence manufactured by Messrs. Cadbury Bros. is free from all admixtures; pure and genuine in the highest sense.

CADBURY'S MILK-CHOCOLATE.—We have also examined a sample of the milk-chocolate prepared by the same manufacturers, and find on analysis that the article is of the same excellent quality as their cocoa.

THE DETECTION OF YEAST EXTRACT AS AN ADULTERANT OF MEAT EXTRACT.

WHILE the test published in the *Pharmaceutical Journal* of October 10th gives satisfactory results in cases of substitution of yeast extract for meat extract, or gross adulteration of one with the other, it is not so suitable for the detection of *small* admixtures of the former. The author of the process above referred to has now worked out a method by which one is enabled to detect an admixture of as little as 1 per cent., and this may act as an efficient corrective to the temptation which dealers will feel to work off by degrees stocks of yeast extract masquerading as genuine meat extract, which are known to have been hurriedly withdrawn from the market since the test was published. If the sample gives doubtful or negative results by that test, but is still open to suspicion, take from 3 to 6 grammes and dissolve in 3 or 6 c.c. water (according to quantity taken); add to this sufficient spirit (methylated will answer the purpose) to throw down *all* that is insoluble in alcohol. After vigorous shaking separate the insoluble residue by decanting or filtering, dissolve this residue in 60 c.c. water, filtered if necessary and proceed as before. If yeast extract is present the characteristic bluish-white precipitate will be thrown down on boiling with the modified Fehling's solution, and may be collected and weighed.

Medical News.

Society of Members of the Royal College of Surgeons in England.

A COUNCIL meeting of this Society was held at 20, Brunswick Square, London, W.C., on January 12th, Mr. Joseph Smith being in the chair. The following resolutions were unanimously agreed to:—1. "That

this council considers the reply of the College Council to the resolutions passed at the last annual meeting of Fellows and members to be most unsatisfactory. Having regard to the repeated refusal to accede to the wishes of the members as expressed in meetings to which they have been specially summoned, this council emphatically repudiates the claim of the College Council to represent the members, and further declares its determination not to abate its efforts to obtain adequate representation for the great majority of the body corporate." 2. "That this council desires to call attention to the inexpediency of appointing a committee to deal with the relations of the medical profession to the coroners' courts composed exclusively of those who are seldom brought into contact with those courts and would suggest the addition to the committee of some Fellows or members outside the College Council having special knowledge of the matter."

Lectures in Medical Jurisprudence.

ON January 14th, Dr. F. J. Waldo, coroner for the City of London, delivered the first of a series of six lectures on medical jurisprudence at the Old Hall, Lincoln's Inn, under the auspices of the Council of Legal Education. The subject of the first lecture was "The Medical Man as Witness." At the outset the abilities and disabilities attached to the registration of medical men were dealt with. A medical man might give evidence either as a common witness to facts or as an expert in matters of deduction and experience. The why and wherefore of conflicting medical evidence were next discussed at some length and reasons were given to show how candid and skilful men could contradict each other in court without sacrifice of honesty. The illustration of this point was taken from "railway spine," cases of accidental injury in which the widest difference of opinion often prevailed. The ending of litigation was often attended by a speedy recovery on the part of the patient. Quite as great or greater differences existed amongst lawyers, as proved by the reversal of decisions, time after time, in successive courts, until the House of Lords was reached. The important question of personal privilege was discussed at considerable length and the illustrations included the recent appeal of a provincial head constable to the local medical men for information likely to identify the offender in a case of infanticide. A medical witness is bound to answer fully in a witness-box if required to do so by the court, except where by so doing he would incriminate himself. In ordinary life, however, any violation of professional secrets might involve an action at law. The unwritten law of the medical profession appeared to be that there was no obligation to reveal anything that come under their notice short of murder or the gravest criminal charges. This professional secrecy dated from the earliest times, as shown by the oath of Hippocrates, the substance of which was still adopted in the declaration of the Scotch medical graduate. The lecturer concluded with an analysis of the various kinds of medical evidence and some of the points concerned in the medical examination of prisoners.

Society for Relief of Widows and Orphans of Medical Men.

A QUARTERLY Court of the Directors of the Society was held on Wednesday, January 13th, Mr. Christopher Heath, the president, being in the chair. Three new members were elected and the death of a member reported. It was resolved to distribute £1,513 among the 53 widows, 15 orphans, and 4 recipients from the Copeland Fund, now in receipt of grants. A sum of £586 was given at Christmas as a present—£10 each to 53 widows, £3 each to 12 orphans, and £5 each to the 4 orphans of the Copeland Fund. The expenses of the quarter were £77 12s. 6d.

Royal British Nurses' Association.

A SPECIAL general meeting of this Association will be held at the rooms of the Medical Society of London, 11 Chandos Street, Cavendish Square, W., on Tuesday, February 2nd, 1904, at 4 p.m., for the purpose of considering the draft of a Bill upon the State registration of trained nurses, which will be submitted to the meeting; and any amendments that may be proposed thereon. The following resolution will be proposed:—"That the draft Bill, as amended, be approved: and that the Executive Committee be directed to take such steps as they may think necessary to have it submitted to Parliament."

City Hospital for Diseases of the Skin and Cancer, Dublin.

THE new quarters of this hospital were formally opened by the Right Hon. T. C. Harrington, M.P., Lord Mayor of Dublin, on Friday, the 22nd inst. The meeting was large and representative, and an urgent appeal for sufficient funds to allow the Governors to establish fifteen beds for acute cases was, we have reason to believe, generously responded to. The attendances registered during the year numbered 5,468, showing an increase of 1,025 over all previous years. The Light department is well equipped, and at very considerable expense. A short demonstration was given by the medical staff of the Finsen Light, X-rays, High Frequency Currents, and Radium.

Institute of Medical Sciences.—London University Appeal.

THE following letter has been addressed to the Earl of Rosebery, Chancellor of the University of London:—

MY LORD,—We have observed with satisfaction that the Senate of the University of London have lately issued an appeal for funds to build and endow an Institute of Medical Sciences under the control of the University. The positions which we severally hold in connection with the general hospitals of London and their medical schools have compelled us, especially of late, to give the proposal that the University should undertake the teaching of the preliminary scientific subjects of the medical curriculum the most serious consideration. We are convinced that the adoption of the recommendation of the Royal Commission in favour of the concentration of the teaching of these subjects in one or more centres has become a matter of urgent necessity, in the interests alike of medical education, of the hospitals, and the medical schools.

We are, my Lord, yours faithfully,

SANDHURST,
Chairman of the Weekly Board, Middlesex Hospital.
TREVOR LAWRENCE.
Treasurer, St. Bartholomew's Hospital.
H. COSMO BONSOR,
Treasurer, Guy's Hospital.
SYDNEY HOLLAND,
Chairman, London Hospital.
J. G. WAINWRIGHT,
Treasurer, St. Thomas's Hospital.
TIMOTHY HOLMES,
Treasurer, St. George's Hospital.
H. A. HARBEN,
Chairman, St. Mary's Hospital.
THOS. PERCY BORRETT,
Chairman, Charing Cross Hospital.
J. WOLFE-BARRY,
Chairman, Westminster Hospital.

A large sum is required to carry out the scheme. The Hon. Treasurers of the Appeal Fund are J. K. Fowler, Member of the Senate, and H. T. Butlin, Dean of the Faculty of Medicine, 35, Clarges Street, W.

Liverpool Medical Institution.

AT the annual meeting held on Thursday, January 14th, 1904, the following list of office bearers and members of council was adopted, viz.,—President: *James Barr. Vice-Presidents: H. Briggs, G. W. Steeves, *J. R. Logan, and *J. Wiglesworth. Treasurer: T. H. Bickerton. General Secretary: *F. C. Larkin. Secretary to the Ordinary Meetings: *R. W. Murray, Secretary to the Pathological Meetings: *W. B. Warrington. Editor of the *Journal*: *F. H. Barendt. Librarian: *A. S. Grünbaum. Council: *H. Adcock, *J. Bark, *H. A. Clarke, A. Fisher, F. T. Paul, J. Pinkerton, *W. Fingland, *A. G. Gullan, *L. Monsarrat, *J. Hay, *R. Parker, and *Edgar Stevenson. Those marked (*) did not hold the same office last year.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MR. P. M.—Regret we are unable to accede to your request, as a like concession would be expected by the various Institutions if conceded to one.

A DISCLAIMER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Our attention has been called to a report of Police Court proceedings under the Merchandise Marks Act, in respect of adulterated soda crystals supplied by a Messrs. Burgoyne and Co., and, as we are commonly known in the trade and medical profession as Burgoyne and Co., we ask the favour of your kindly inserting this letter disclaiming any connection with the house, or proceedings in question.

Thanking you in anticipation of your compliance with this request,

We remain,

Yours faithfully,

BURGOYNE, BURBIDGES & Co.

THIRD YEAR'S STUDENT.—Yes, it is certainly the best manual of Surgery for you, but we understand there is another edition in the press and would advise you to wait for this. You will probably be able to refer to the existing edition in your college meanwhile.

Dr. J. A. S.—As you are retiring on account of ill health, there should be no difficulty in disposing of your practice. Your best plan will be to put the matter in the hands of a reliable transfer agent, who will relieve you of all trouble and anxiety. If you are not acquainted with one, the information will be found on reference to our advertisement columns.

LIEBIG'S EXTRACT: A DISCLAIMER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As makers of the greater part of the world's supply of Meat Extract, will you allow us to disclaim connection in any way with the firm which was summoned at the Liverpool City Police Court for selling Extract of Beef as Liebig's Canadian Extract of Beef, as reported in your Journal of the 13th inst.

We are the pioneers in the manufacture of Meat Extract, and Baron Justus von Liebig was the head of our Scientific Department from the inception of our Company until his death. He gave us the exclusive right to use his name on condition that the extract was prepared in accordance with certain private formulas which he passed on to us, and that every consignment of Extract was analysed, examined and approved personally by him and his successors, before it reached the public. The most eminent scientific men have carried on this control since his death: and Sir Henry Roscoe, F.R.S., Ph.D., D.C.L., is the present head of our British Scientific Department.

Every ounce of Lemco and Oxo is made under the personal supervision of our own staff and scientific advisers, from prime cattle reared mainly on our own farms, and it was to dissociate ourselves from our many imitators that we adopted the trade name "Lemco" for the only genuine Liebig Company's Extract.

Since your report has led persons to connect us with the case, we trust you will allow us to make this disclaimer.

Yours faithfully,

For Liebig's Extract of Meat Company, Limited,

R. GILLIGAN, *Secretary*.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 27th.

HUNTERIAN SOCIETY.—(London Institution, Finsbury Circus, E.C.)—8.30 p.m. Pathological Evening.

MEDICAL GRADUATES' COLLEGE and POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. P. Paton: Clinique. (Surgical.) 5.15 p.m. Dr. W. Carr: Infant Feeding.

THURSDAY, JANUARY 28th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Cases will be shown by Mr. G. W. Thompson, Mr. E. T. Collins, Mr. G. W. Roll, Mr. S. J. Taylor, Dr. L. Werner, and Dr. D. Mowat, 8.30 p.m. Papers:—Mr. A. H. Jessop: Cases of Ptosis.—Mr. G. Brooksbank-James: A Plan of Treatment in some Cases of Asthenopia.—Mr. W. M. Beaumont: A Note on the Eye Symptoms of Rheumatoid Arthritis with a Special Reference to the Field of Vision.—Major Maynard and Dr. L. Rogers: Pulsating Exophthalmos due to Dilatation and Dropsy of the Optic Nerve, accompanying Internal Hydrocephalus.—Mr. J. R. Lunn: Notes of a Case of Tuberculosis of the Choroid.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. L. Cheatle: Operations for Cancer of the Tongue and Nasolabial Regions.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Dr. G. Johnston: Fibrosis of the Lungs, I. (with cases). (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.). 6.15 p.m. Dr. M. Dockrell: Syphilis. (Chesterfield Lecture.)

FRIDAY, JANUARY 29th.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos Street, Cavendish Square, W.).—Cases will be shown by Dr. Kelson, Dr. W. Wingrave, Dr. A. Wylie, Mr. M. Collier, and Mr. Stuart-Low. The President: Annual Address. Communication—Mr. M. Collier.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. H. Tilley: Clinique. (Throat.)

THURSDAY, FEBRUARY 4th.

ROENTGEN SOCIETY (20, Hanover Square).—8.30 p.m. Ordinary General Meeting. Discussion upon the "Production of Photographic Reversal through the Action of Various Radiations."

Appointments.

BOTTON, A. J. H., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory Act for the Watlington District of the county of Oxford.

BUTTERWORTH, RUPERT, M.B.Cantab., House Physician to the Derbyshire Royal Infirmary.

COLERIDGE, A., M.R.C.S., L.R.C.P.Lond., Senior Resident Medical Officer at the Mount Vernon Consumption Hospital, Hampstead.

CONDELL, A. P., M.D., Clinical Assistant to the Chelsea Hospital for Women.

DONALD, C. W., M.B., F.R.C.S.Ed., Assistant Honorary Physician to the Cumberland Infirmary, Carlisle.

EVANS, J. HOWELL, M.B., M.Ch.Oxon., F.R.C.S.Eng., Registrar to the Chelsea Hospital for Women.

GOODWIN, ROBERT, M.D., Clinical Assistant to the Chelsea Hospital for Women.

HARDY, PERCY, M.R.C.S., L.R.C.P.Lond., Assistant House Surgeon to the Derbyshire Royal Infirmary.

HIGHT, JOHN, M.D. Glas., D.P.H., Medical Officer of Health of Burgh of Prestwick, Ayrshire.

JONES, H. BUCKLAND, M.B., M.Ch. Edin., Assistant Surgeon to the Metropolitan, Ear, Nose, and Throat Hospital.

KIRKBY, WALTER, L.R.C.P., L.R.C.S., L.F.P.S.Glas., Medical Examiner of Recruits for the Glamorgan Imperial Yeomanry in the Maesteg District.

MUMMERY, J. P. LOCKHART, B.C Cantab., F.R.C.S Eng., Assistant Surgeon to St. Mark's Hospital for Fistula and other Diseases of the Rectum, City Road, London, E.C.

PHILLIPS, JAMES, F.R.C.S Ed., Honorary Surgeon to the Bradford (Yorks) Children's Hospital.

ROSE, THOMAS, M.R.C.S., L.R.C.P.Lond., Resident Medical Officer to the Chelsea Hospital for Women.

Vacancies.

Corporation of Manchester.—Monsall Fever Hospital.—Fourth Medical Assistant, Salary £100 per annum, with board, lodgings, and washing. Applications to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester.

Hampstead General Hospital.—Resident Medical Officer, Salary £120 per annum, with rooms, coal, and gas. Applications to George Watts, Secretary.

North Riding Infirmary, Middlesbrough, Yorkshire.—Assistant House Surgeon, Salary £75 per annum, with bed board, and washing. Applications to Angus Macpherson, Secretary.

Poplar Union.—Medical Officer, Salary £130 per annum. Applications to G. Herbert Lough, Union Offices, 45, Upper North Street, Poplar, E.

York Dispensary.—Resident Medical Officer, Salary £120 per annum, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York

Births.

CHARLES.—On January 20, at Pelsall, Staffordshire, the wife of J. R. Charles, M.D., M.R.C.P., of a son.

MAY.—On January 20th, at Ivanhoe, 50, Archers Road, Southampton the wife of Henry J. May, M.B., B.C. (Cantab.), of a daughter.

WILLIAMS.—On January 19th, at Bryn Derw, Penarth, the wife of W. Williams, M.A., M.D., D.P.H., County Medical Officer, of a son.

YELD.—On January 22nd, at 15, Gloucester Road, Regent's Park, the wife of Walter H. Yeld, M.R.C.S.Eng., L.R.C.P.Lond., of a daughter.

Marriages.

TRAILL-THOMPSON—BELL.—On January 20th, at Christ Church, Lancaster Gate, W., W. D. Traill-Thompson, M.B., B.Ch., Knottsall, Wembley, second son of G. Thompson, Esq., late Inspector General of Education, C.P. India, to May, second daughter of the late C. Seymour Bell, Esq., Carlton Hall, Yorks.

Deaths.

BOULTON.—On January 20th, at Ingham, nr. Lincoln, Mary E. Boulton, wife of George S. Boulton, M.R.C.S., aged 56.

PAIN.—On December 8th, at C.M.S. Hospital, Old Cairo, Ethel Blanche, the wife of E. Maynard Pain, Esq., M.B., Ch.M.

WILLIAMSON.—On January 15th, at Southsea, Mary, relict of John Williamson, Esq., M.D., of Grahamstown, S. Africa, and third daughter of Thos. Stringer, Esq. J.P., of Sycamore Hill, Macclesfield, aged 67. South African papers, please copy.

"SALUS POPULI SUPREMA LEX."

VOL. CXXVIII. WEDNESDAY, FEBRUARY 3, 1904. No. 5.

A Clinical Lecture
ON
SOME PNEUMONIAS,

DELIVERED AT THE WESTMINSTER HOSPITAL

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician to the Hospital, Joint Lecturer on Medicine, and Lecturer on Clinical Medicine.

ACUTE lobar pneumonia is a fairly common disease, the symptom-picture of which is readily recognised. The patient is usually a young man who gives a definite history of exposure to cold and wet. The onset is sudden, there is a rigor of some intensity, the temperature is 103° or 104°, the pulse-rate 120, whilst the frequency of respiration is notably increased. There is acute pain in the side, not from inflammation of the lung itself, but from the accompanying pleurisy. The patient feels very ill and readily takes to his bed, the face wears an anxious expression, and is flushed often only on the side corresponding to the seat of the disease. The cough is short and hard, and the expectoration, at first absent, is soon "rusty" or "greengage" in character. The skin is dry and pungent, thirst is a prominent symptom, and there are pains in the limbs. There is also a rash, the herpes labialis or herpes facialis. It is usually seen on the upper lip either at the angle of the mouth or just under one or other nostril, but it may be on the cheek, chin or jaw. It is said that the patch of herpes is on the same side as the lung involved, but this is not always the case. In double pneumonia there may be double herpes, but this is not an invariable rule. Inequality of the pupils is not uncommon in pneumonia, the dilated pupil being usually on the affected side. The dilatation of the pupil is due to irritation of that portion of the sympathetic which acts as the pupil dilator. Usually the herpes and the dilated pupil are on the same side, but here again exceptions are not uncommon. Herpes labialis is not peculiar to pneumonia, and often occurs as the result of a febrile cold or of gastric disturbance. Herpes is attended with elevation of temperature, and it is not always easy to distinguish herpetic fever from pneumonic fever. Cases are from time to time seen of reputed pneumonia without physical signs, there being a sudden onset, a sharp rise of temperature, with termination by crisis and other symptoms closely simulating pneumonia. It will be found in most of these cases that herpes labialis is present, and that they are examples of herpetic fever. It is not, however, every case of herpes which is attended with elevation of temperature. We recently had in the wards a girl, æt. 11, suffering from Todd's paralytic chorea, whose temperature taken every four hours was always normal. She developed herpes on both sides of the lower lip which lasted seven days. There was no pneumonia, and there was no disturbance of temperature. The herpes in inflammation of the lungs sometimes makes its appearance on the tonsil and pharynx, and I have known a case of this description, in a child, diagnosed as tuberculous meningitis. An attack of acute lobar pneumonia usually terminates by crisis, indicated not only by a sudden fall in temperature but by an attack of diarrhœa or profuse sweating, and a subsidence of all the acute symptoms. The critical period is said to be the fifth day, but the statistics of the Westminster Hospital show that it is commoner on the sixth day than on the fifth, and still more frequent on the seventh. As a matter of expediency it is safer to prognosticate that the crisis will be about the eighth day, beyond which it is not likely to be postponed. In termination by crisis there is not uncommonly a pseudo-crisis, or temporary fall in temperature, before the actual crisis, and a post-critical rise is frequently seen. When the termination is by lysis it is spread over a couple of days or more, usually the seventh and eighth.

With regard to the bacteriology of the disease, Fränkel's pneumococcus or diplococcus is the essential organism. It is commonly spoken of as the diplococcus pneumoniæ, but the term streptococcus lanceolatus is sometimes used. It is not always pathogenic, and is present in the saliva and nasal secretions of many healthy people. As a rule, it exerts no morbific influence, but when the resistive powers are lowered by exposure to cold and wet, or other depressing agencies, it attacks the lungs and the patient gets pneumonia. The microscopical examination of sputum for determining the diagnosis of suspected pneumonia is not absolutely certain, for the observation is complicated by the fact that diplococci are frequently present in the mouth in large numbers. When pneumococci are obtained from the mouths of healthy individuals the virulence is not so high, nor can it be so easily increased as when they are derived from pathological lesions. A more trustworthy test is that afforded by inoculation, for the oral diplococci, if present, are usually too few or not sufficiently virulent to produce effects. Moreover, diplococci are not uncommonly found in the lungs of healthy persons. Fränkel's pneumococcus is responsible for a good many morbid manifestations. In addition to acute lobar pneumonia, it may give rise to pneumococcic arthritis, often mistaken for acute rheumatism, to pleurisy and empyema, endocarditis and pericarditis, salpingitis and peritonitis, otitis media with cellulitis and the formation of multiple abscesses, meningitis, and many other forms of disease. Pneumococcic tonsilitis is a condition often accompanied by rusty expectoration, a point worth remembering in connection with diagnosis. The pleurisy which accompanies pneumonia is pneumococcic in origin. It is now recognised that the diplococcus may enter through the lungs and produce remote effects without causing pneumonia. Friedländer's pneumobacillus is not the essential cause of pneumonia, although frequently found in connection with it. It does not stand in the same relation to pneumonia that the tubercle bacillus does to phthisis, although in some cases of pneumonia Friedländer's bacillus is present whilst Fränkel's pneumococcus is absent.

Weichselbaum, of Vienna, as a result of an examination of 129 cases of pneumonia, found Fränkel's diplococcus in 94 and Friedländer's pneumococcus in only 9. It is probable that several varieties of pneumococcus exist. Foà described two distinct varieties. One he calls simply the pneumococcus, whilst the other he names meningococcus. He found that rabbits

immunised against the pneumococcus were not immunised against the meningococcus, and *vice versâ*. Various strains of pneumococci differ much in their virulence. Certain lesions will occur with some varieties and not with others; for example, with some broncho-pneumonia is produced, whilst with others acute lobar pneumonia.

There is often a mixed infection, and in some cases classed as pneumonia, streptococcus pyogenes and staphylococcus pyogenes aureus have been the prevalent organisms. Other organisms found in connection with pneumonia are those characteristic of influenza, enteric fever, and diphtheria. In an outbreak of epidemic pneumonia at Middlesbrough, Klein was unable to discover either the diplococcus of Fränkel or the pneumococcus of Friedländer, but found instead a distinctive bacillus, a mobile rod-shaped microbe. It is clear that whilst one organism is most frequently found associated with pneumonia there are others capable of producing a closely allied if not identical condition. If is often said "no pneumococci no pneumonia," but it is doubtful if this statement is correct. In an apparently typical case of acute lobar pneumonia recently in the wards, the rusty, viscid expectoration was examined many times, but no diplococci were found. It is possible that cocci may have been present in some of the expectoration, but they were absent in the specimen examined. A similar experience is met with in phthisis, for although there may be abundance of bacilli in the lungs the specimen examined may have come from the larynx or nasal passages.

The treatment of asthenic pneumonia presents many points of interest. The patient is knocked down by the severity of the blow, and readily takes to his bed, it being rare to meet with "ambulatory" cases, such as are seen in enteric fever. If the tongue is foul it is a good plan to begin with a dose of calomel, three grains for a private patient and ten grains in hospital practice. The diet should consist of three pints of milk—five ounces every alternate hour—or two pints of milk and one of beef-tea in the twenty-four hours. If there is no expectoration, or if it is scanty and viscid, three drops of antimonial wine may be given every two or three hours. The antimonial treatment is indicated chiefly in the very early stage of the disease, when the skin is hot and dry and the expectoration tenacious. After the first twenty-four hours five grains of carbonate of ammonium may be given in milk every four hours. In cases of delayed resolution, five grains of carbonate of ammonium, ten grains of chloride of ammonium, and five of iodide of potassium every four hours in an ounce of water flavoured with a drachm of liquid extract of liquorice and fifteen minims of spirits of chloroform, will be found useful. If the pain in the side is acute, linseed meal poultices, hot fomentations, equal parts of extract of belladonna and glycerin, iodine, or a chloroform poultice may be applied. If the heart shows signs of failing, two drachms of freshly prepared infusion of digitalis every four hours, or a hypodermic injection of 1-20th grain of strychnine will do good. When there is much dyspnœa with commencing cyanosis, copious inhalations of oxygen usually afford temporary relief. If the crisis is unduly delayed, a single dose of an ounce of Warburg's tincture, either by mouth or rectum, may determine it. Stimulants usually have to be given freely, and old liqueur brandy will be found the best, the ordinary "three star" being of little value for this purpose. Very old brandy, which consists of various forms of ether and is of comparatively low alcoholic strength, commands a high price, and the 1823 and 1821 vintages are not readily obtainable. Champagne is another good form of stimulant, but it must be of some age and standing, for immature wine is of little value. Delbeck 1893 is a light champagne, and I often have given a bottle in the twenty-four hours when the pulse is weak and running. The ordinary half-bottle of champagne holds 13 oz.

The treatment of pneumonia by means of an anti-pneumoccocic serum hardly falls within the range of practical therapeutics. The late Dr. J. W. Washbourn was the first to immunise a horse, and to obtain sufficient serum for the treatment of cases of pneumonia. The serum was of such potency that 0·03 cc., when mixed with ten lethal doses of living pneumococci and the mixture injected into the peritoneal cavity of a rabbit, prevented death. Several cases of pneumonia were treated with the serum with satisfactory results, but subsequent observations showed that clinically it was of little value. Mennes obtained a protective serum from horses and Pane one from donkeys, but they have not come into general use. It is probable that they are antibacterial, but not antitoxic.

SECONDARY OR INTERCURRENT PNEUMONIA engrafted on some other pre-existing disease is more common than the acute lobar form. It may supervene insidiously on various disorders, such as influenza, diphtheria, enteric fever, small-pox, erysipelas, and puerperal septicæmia. In these cases the symptoms are but slightly pronounced and the inflammation steals upon the lung and does irrevocable injury without giving any notice of its presence except such as may be gathered by a careful and systematic examination of the chest. It is not a common accompaniment of bronchitis, phthisis, or pleurisy, but it frequently ends the scene in carcinoma and chronic affections of the kidneys and of the nervous system. Influenza in some epidemics is commonly accompanied by pneumonia, and this was the case in the outbreak in 1889-90. The soil of the influenza bacillus appears to be favourable to the growth of the pneumococcus. Pfeiffer's bacillus may be found alone or in association with pneumococcus or streptococcus pyogenes or both. The type of influenzal pneumonia is broncho-pneumonic with acute interstitial changes. There is no initial rigor, and expectoration may be absent, or, if present, of the muco-purulent rather than the rusty variety. The physical signs may not be detected for some days, and the dulness is usually patchy or scrapy, and not confined to the base or to one lobe. Not uncommonly there is a gradual diffusion of the inflammation throughout the whole of one or both lungs. These cases are prolonged and tend to terminate by lysis, rather than by crisis. Prostration is a prominent feature, and alcoholic stimulants have to be administered freely. Death not infrequently supervenes at an early stage of the disease. Enteric pneumonia is another common form of secondary pneumonia. In every case of pneumonia it is necessary to consider whether the disease is primary or secondary, and if secondary if the primary disease is enteric. It makes all the difference not only in prognosis but in treatment. I have known a patient treated for acute lobar pneumonia for days without the slightest suspicion that it was secondary to typhoid fever, and that at a stage when there was a characteristic roseolar rash on the abdomen. The patient had been fed on chops and steaks, and died of perforation. Some cases of enteric fever practically begin with pneumonia; that is, the symptoms from the first are those of inflammation of the lungs, and it is not until later that the true nature of the disease is suspected. In case of doubt it is essential to diet the patient on the supposition that he has enteric. An acute pneumonia will do well on three pints of milk a day, whilst an enteric case will certainly do badly on a solid dietary. In many cases of enteric the symptoms of pneumonia are not observed until the second or third week, and even then the pain and rusty expectoration are commonly absent. Frequently the complication is recognised only by the dyspnœa, the increased elevation of temperature, and the by no means pronounced physical signs. In the majority of cases the pneumonia is pneumococcic in origin, but in others the enteric bacillus is detected in the expectoration, and sometimes in addition streptococci are found. The term "typhoid pneumonia" is frequently applied to patients who present a "typhoid" condition, and it must not be regarded as synonymous with enteric pneumonia. Diphtheritic, plague, and erysipelatous pneumonias are well-known varieties of the disease. The usual

complication of diphtheria in this connection is broncho-pneumonia, due not to the Klebs-Löffler bacillus but to pyogenic cocci taken in during respiration. Erysipelatous pneumonia may occur in the course of erysipelas migrans, the inflammation affecting first the skin, then the mucous membranes, and finally spreading to the lungs. It is a good example of migratory or wandering pneumonia. Convalescence is likely to be prolonged and attended with much prostration. Pneumonia may occur in connection with pulmonary aspergillosis, although the pulmonary symptoms are usually more closely allied to tuberculosis. In actinomycosis, portions of the lung are converted into tough fibrous material having an irregular interlobular distribution. In pulmonary anthrax there is a condition allied to pneumonia, the lungs on section being congested and œdematous with large extravasations of blood.

It is probable that in the majority of cases secondary pneumonia is a purely local inflammation due to the action of the specific poison, and not differing essentially from inflammation of other organs and structures due to the same cause.

Latent or Asthenic Pneumonia.—These are cases in which the characteristic symptoms of the disease are absent or are masked by other clinical phenomena. In elderly people there is no initial rigor, and the presence of the disease may be revealed only by the prostration, headache and delirium, none of the usual symptoms of invasion being observed. The cough and expectoration may be absent, and the latter, if present, may fail to present the characteristic appearance and may be simply viscid or puriform. The flushed face is not common and the face is commonly pale and sunken. Fever is present, but is rarely high. This elevation of temperature, however, is sufficient to put the observer on his guard, for pneumonia is one of the few febrile disorders from which old people suffer. Most cases of secondary pneumonia tend to assume an asthenic type. There is intense prostration with great depression of the nervous centres. This variety is often met with in people who are alcoholic, and in them the prognosis is grave. Death may occur early, and in cases of recovery convalescence is prolonged. Cheyne-Stokes respiration is a bad sign, and marks the beginning of the end. Stimulants are indicated, and it is in this variety that musk is most likely to do good. It should be administered in four-grain doses in pill every four hours. It is an expensive remedy, and at one time cost 2s. 6d. a grain, but is now cheaper. Sumbul has been proposed as a substitute, but has not the same therapeutical action.

Cardiac Pneumonia is a common disease, although some writers seem to doubt its existence, and speak of it as a condition of hyperæmia or congestion. It is a not uncommon complication of mitral stenosis, pericarditis, and fatty degeneration. The temperature rises suddenly, there is a short, dry, hacking cough, the expectoration is rusty, and fine crepitation is heard over one or both lungs. At the autopsy, in addition to pulmonary infarcts, hæmorrhage, extravasation, and hepatisation are found. A girl, æt. 20, was recently admitted with acute rheumatism followed by endocarditis (mitral regurgitation) and pericarditis with effusion. A week later there was a sudden rise of temperature, and the patient was found to have fine crepitation at the base of both lungs posteriorly, more marked on the right than on the left. There was no rigor, the cough was slight and hacking, whilst the expectoration was rusty and streaked with blood. No tubercle bacilli were present, and the organisms, which were not numerous, consisted for the most part of short, thick bacilli, and of cocci in pairs, but not resembling the diplococcus pneumoniæ. There was a crisis on the seventh day, but the patient died a month after admission of acute endocarditis not septic in origin. The treatment of these cases in which there is a damaged heart as the result of rheumatic fever requires much care. Antimonial wine may be useful, but ten or fifteen minims of solution of hydrochlorate of apomorphine by mouth every three hours gives better results, chiefly by promoting expectoration. Counter-irritation over both bases should not be neglected. Stimulants, especially in the form of champagne and old brandy, are indispensable, and when the heart shows signs of failure and the pulse is frequent, irregular and intermittent, half-ounce doses of freshly prepared infusion of digitalis every three hours, with hypodermic injection of 1-20th grain of strychnine, are useful.

Traumatic and Contusion Pneumonia.—Traumatic pneumonia is the natural sequence of penetrating wounds of the lung. It differs from idiopathic pneumonia in exhibiting very little tendency to diffuse itself through the lung. It shows no predilection for the base, and as a rule is strictly localised. It is asthenic in type, and is accompanied by active febrile disturbance. It may terminate in abscess, but usually the lung exhibits a remarkable power of recovery from even extensive injury.

Contusion pneumonia may follow blows on the chest-wall or falls. It was at one time considered doubtful whether external violence, short of lung laceration, was capable of producing pneumonia, but the fact is now established that inflammation of the lung having all the characters of acute lobar pneumonia may ensue. This is a matter of importance in connection with claims against accident insurance companies. If a person meets with an accident and subsequently dies of pneumonia it is not always easy to say whether the condition of the lungs is primary or secondary to the injury. It is probable that in some cases a blow on the chest lowers the vitality of the subjacent portion of the lung, whilst a subsequent exposure to cold or wet determines the onset of the disease. A street scavenger, æt. 31, was admitted to the hospital having been knocked down by a hansom cab, the wheel of which passed diagonally over the lumbar region and the left side of the chest. On admission, he was not collapsed, and there was no evidence of fracture of the ribs or injury to the liver. The urine was smoky in appearance, and as the patient had been in South Africa it was examined for bilharzia, but nothing was found. On the day following the injury a patch of fine crepitation was detected near the angle of the scapula on the injured side. There was no rigor and no elevation of temperature. The same night the patient commenced coughing, and the expectoration was rusty in character. The crepitation persisted for some days. There was no herpes, and no pleuritic effusion, and the patient made a good recovery.

Septic or Streptococcic Pneumonia.—The term "septic" is sometimes applied to cases of pneumonia originating in bad sanitary conditions, especially exposure to sewer gas. A true septic pneumonia may arise in connection with a wound or trivial abrasion, and the entrance into the system of either streptococci or staphylococci or both. A patient admitted for pneumonia is found to have an abrasion on the finger. There is no tenderness of the lymphatics, and there are no enlarged glands in the axilla. There is no cough or expectoration, the physical signs are not those of acute lobar pneumonia, and there is no crisis. The condition of the lung is apparently secondary, but there is nothing to connect it with the wound. The temperature is high, but not hectic in type. Anti-streptococcic serum does no good, and anti-staphylococcic serum is equally inefficacious. There are frequent shiverings, a very rapid and feeble pulse, with profuse perspirations, and death ensues by asthenia. At the autopsy a general pyæmic condition is found, and cultures show a mixed infection, probably having its origin in the wound. These cases are often extremely puzzling. Some writers limit the term septic to post-operation pneumonias in which there is absorption of septic material from open wounds. Cases of parturient pneumonia come within this category. Septic pneumonia following pregnancy is not especially fatal, but the prognosis of idiopathic pneumonia both in pregnant and parturient women is extremely bad. In many cases of septic pneumonia both pneumococci and streptococci are found in the expectoration. When the streptococcus infection predominates the onset is less

abrupt than in the pneumococcic form, but the fever is of a hectic type, and there may be a succession of rigors. The physical signs are usually few and doubtful, and there may be little or no dulness on percussion. If the inflamed lobules are near the surface moist sounds may be audible. The most notable feature is the long duration, with the shifting character of the physical signs. Termination is usually by lysis, and convalescence is as prolonged as in enteric fever.

ANÆSTHETIC PNEUMONIA.—This occurs most frequently after the administration of ether, but is occasionally seen after chloroform. Ether pneumonia may be due to the irritation produced by the anæsthetic itself, by exposure of the patient to cold, especially in abdominal explorations, and possibly in some cases from the use of a contaminated mouth-piece. It has been suggested that prior to the administration of the anæsthetic the mouth, throat, and nasal passages should be rendered aseptic by the use of a mouth-wash and gargle. The symptoms of pneumonia may make their appearance in from five to seven hours after the operation, or they may be postponed for some days. The mortality in cases of ether pneumonia is said to be about 50 per cent., whilst in chloroform pneumonia it is higher.

THE DIAGNOSIS AND INDICATIONS FOR OPERATION IN ACUTE APPENDICITIS. (*a*)

By W. RUSSELL, M.D.Ed., F.R.C.P.,
Assistant Physician, Royal Infirmary, Edinburgh, &c.

IN his introductory remarks Dr. Russell alluded to the seeming paradox that, while each of us relied in practice on his individual experience, this individual experience was of little value as compared with collective experience. For twenty-one years the appendix vermiformis had been recognised as the great cause of trouble in the cæcal region, and concomitantly therewith the terms perityphlitis and typhlitis had almost dropped entirely into disuse, some, indeed, being inclined to deny that such conditions existed. Nevertheless, Dr. Russell thought that in a small percentage of cases the cæcum was primarily at fault. He had three bad cases of perforation of a fæcal ulcer of the cæcum, and one of perityphlitic abscess, in which there was proof that the vermiform appendix was not involved. In approaching the question of diagnosis, it was necessary to have a clear conception of the conditions which favour the occurrence of the disease, and the essential points in its varying intensity. He thought that the anatomical conditions of the appendix, especially the length of the mesocolon, were of importance in predisposing to the disease. The mesocolon contained the vessels of the appendix, though in women there was an additional vascular supply (which might account for the lesser frequency of appendicitis in females), so that its length might have some effect on the ease with which the blood supply was interfered with. Again, variations in the length and position of the appendix, and variations in the ratio of its calibre and length to the lumen of the cæcum, might make some appendices more liable than others to defective drainage. Appendicitis—catarrhal, ulcerative, perforative, or gangrenous—was most likely to occur when the organ was sickle-shaped, and had a short mesentery. Some persons, in fact, had appendices which, from their anatomical peculiarities, were bound to give trouble, sooner or later. Interference with the drainage of the appendix played an important part in determining inflammation. The bacillus coli, though not the only organism, was that usually present in appendicitis, and its virulence varied greatly in different cases. It was exalted by any morbid condition of the intestine—diarrhœa, constipation, or obstruction. It must be remembered that the drainage of the appendix could be interfered with by its being blocked by a catarrh of the cæcum, or the blockage might be wholly or partially due to fæcal concretions, which were especially frequent in the fulminating types. In very rare cases appendicitis had been caused by a gall-stone occluding the appendix. Before discussing the symptomatology of an acute attack, the speaker referred to "appendicular colic," in which transitory symptoms of appendicitis recurred at intervals, but no local signs could ever be made out. He thought that such a condition must be recognised; it seemed to be due to the engagement of a fæcal mass in the mouth of the appendix, and disappeared after a dose of castor oil. This appendicular colic may, or may not, go on to appendicitis. The symptoms of such appendicitis were common to other diseases. As to *pain*, he thought that too much stress might be laid on its seat; it was often general, around the umbilicus, or referred, and was, especially when associated with cutaneous hyperæsthesia, very often misleading. *Deeply-seated tenderness*, on the contrary, was the key to all abdominal diagnosis, and though the tension of the abdominal muscles might make it difficult to elicit, careful deep palpation would overcome this, and enable us to detect the painful diseased appendix. Sometimes it could be most readily made out by rectal examination, when it dipped down into the pelvis instead of being an abdominal organ. He did not dwell on the other symptoms of appendicitis—the vomiting, muscular rigidity, pulse rate, temperature, appearance of shock, &c. The diagnosis depended upon individual skill in eliciting the essential, and distinguishing it from the non-essential. Deep-seated tenderness was, he repeated, the safest guide.

Indications for Operation.—At the outset of this consideration, two schools had to be faced—the radical school, represented in America and France; the conservative school, represented in Britain, France and Germany. If Lequen's aphorism, "toute appendicite doit être operée à temps," were accepted, the position was simple, and there was nothing to discuss. The chief argument of those who held the radical view was that in every case there was great danger of perforation, and that this danger could never be foreseen. The opinions of the conservative school, as represented by Treves, Talamon, Hawkins, and Nothnagel, were then quoted. Statistics showed that about 90 or 95 per cent. of cases of acute appendicitis recovered. Thus Fürbinger had had 120 cases with a mortality of 1; Guttmann, a recovery-rate of 91-92 per cent.; Curschmann, a recovery-rate of 96 per cent.; Sahli had had a series of 453 cases with a mortality of 4·5 per cent., and only nine cases treated surgically. In another series of 7,213 cases, of which over 6,000 were operated upon, about 8 per cent. died. In the Edinburgh Royal Infirmary, of

(*a*) Abstract of Paper to introduce discussion on subject at the Edinburgh Medico-Chirurgical Society, January 20th, 1904.

268 consecutive cases treated in the medical wards, 169 were cured, 7 relieved, 29 died, and the rest were transferred to the surgeons. The supreme question at the outset of every case was: Is the appendix rapidly about to perforate or to become rapidly gangrenous? The chance was about nine to one against this, but the responsibility of deciding which was the one case out of every ten that would require operation was none the less, perhaps more, onerous on this account. He had come to the following conclusions as to operation:—(1) In an acute attack which has been preceded by one or two mild ones immediate operation should be advised, because probably the anatomical condition of the appendix was such as to render it liable to become inflamed. (2) Cases in which there was an early rigor should be operated on at once. (3) Fulminating cases of course required immediate operation. There remained over, however, the great balance of acute cases; in these medical treatment might first be adopted. Purgatives he never now ventured to give. Pain should be relieved by heat or an ice-bag. The question of giving opium arose; Nothnagel thought it should only be administered to relieve pain, and that a call for its continued use indicated operation. He knew that it masked symptoms to some extent, but not so much, he thought, as to forbid its use absolutely. He preferred belladonna, however, which only alleviated the spasm. He was inclined to commend lavage of the bowel, as advised by Bourget, of Lausanne. How long should medication be continued, and what are the indications for operation? As to this, he thought that (1) continued pain was an indication, as it pointed to a severe inflammation and blocking; (2) a recurrent spasmodic pain showed that the appendix was not draining itself, and should be removed; (3) if the pain is severe, but the other symptoms mild, we should be on our guard; (4) the leucocyte count gave little help in cases of gangrene; here deep palpation was of great value; (5) in less acute cases increasing temperature, pulse, and leucocytosis indicated operation; (6) obvious evidence of peritoneal infection was also an indication. He summarised his paper as follows:—Bear in mind variations in the anatomy of the appendix. Consider the question of drainage of the appendix into the cæcum. Appendicular colic is a danger signal. Deep palpation is of paramount importance in all abdominal diseases, and the site of pain as shown by it out best guide. From statistics, it seems that 95 per cent. of patients recover. All cases beginning with rigors should be operated upon; also all second attacks. Fulminating cases have only deep tenderness, little local reaction. Medical treatment should not be continued for more than twenty-four to forty-eight hours, unless there is improvement. Continuance of symptoms and increasing leucocytosis indicate operation.

PROFESSOR HOWARD MARSH, F.R.C.S., delivered his inaugural lecture as Professor of Surgery at the University of Cambridge last Friday, and met with a most cordial reception in the anatomical lecture-room.

THE new Anglo-American hospital at Ghezireh, Egypt, was opened last week by Lady Cromer. The sum of £10,700 has been subscribed for the erection of the building, the principal donor being Sir Ernest Cassel, who contributed £5,000.

MODERN PHYSICAL THERAPEUTICS. (a)

By W. S. HEDLEY, M.D.,

Physician in charge of the Electrical Department, London Hospital.

HE first referred to Professor Dewar's discovering the presence of helium when examining the gases collected over the King's Bath at Bath, and to the fact that Sir W. Ramsay and Mr. Soddy had seen the spectrum of helium develop in a vacuum tube into which nothing but the radiation and "emanation" of radium had been admitted. In other words, radium develops helium by a spontaneous change. Thus a sample of the deposit from the Royal Bath was found to contain radium in appreciable quantity. It therefore seemed possible that a substance undergoing such constant change and disintegration as does an atom of radium might fling off from itself something that might endow the water with therapeutic value. Such substance being in a "nascent" form might help to explain the comparative inefficacy of the waters of certain springs when removed from their source; and the same fact might, perhaps, supply a reason for the recognised difficulty of making successful artificial imitations of the waters of mineral springs. The radiations of radium were then considered, the "Alpha" rays being shown on the spinthariscope, and those from polonium on the zinc screen. The bactericidal properties and therapeutic applications of radio-active substances were then considered, and "applicators" for throat, nose and gynæcological work were shown, as well as thorium, pitchblende, and other plasters, kindly made up by Mr. Martindale for the occasion. The "N" or Blondlot rays were then discussed, their place in the scale being apparently between the infra-red and the shortest wave length of the Hertsian waves. They seem to bridge the gap between electrical action and radiant energy. Professor Charpentin had shown that these rays are emitted from nervous tissue in proportion to its quantity, its physiological activity, or its injury. It would seem that destructive decomposition of the tissue, whether physiological, as in generation of nervous energy, or what may be called pathological, as in the case of herring brine, is a source of "N" rays. It is rumoured that radium is soon to find a rival in the destructive distillation of herring brine; at least, this and guano are now being experimented upon as a source of radio-activity.

The therapeutic action of heat was then dealt with, as well as light of various colours, and the necessity for the use of the actinometer to secure definite and accurate dosage. The importance of measurement of the quality and quantity of X-rays was also insisted upon, and a new method was demonstrated of ascertaining by measuring this on a milliamperemeter, the rectified current passing through a focus tube; also by the radio-chronometer. High frequency currents were considered, and a tendency noticed to desert the methods of the condensation couch and auto-conduction for bipolar effluvation—the latter being demonstrated. The fatal effects of high-frequency currents on the lower animals was then referred to.

(a) Abstract of Paper read before the Balneological Society, January 20th, 1904.

THE CLINICAL IMPORTANCE OF THE LYMPHATIC GLANDS CONTAINED IN THE THICKNESS OF THE CHEEK.

By M. TRENDEL, M.D.,

Professor at the University of Tubingen.

THE existence of lymphatic glands in the thickness of the cheek was shown some time since by Poncet, of Lyons, who demonstrated their frequent existence and described their exact situation. Briefly stated, these glands may be divided into three groups—(1) a maxillary or supra-mandibular group, consisting of one or two glands which lie between the facial artery and vein at the anterior margin of the masseter muscle; (2) a buccinator group, situated on the external surface of the buccinator muscle, more rarely in its thickness, or even between the muscle and the buccal mucous membrane, just below the level of a line drawn from the labial commissure to the lobule of the ear. This group may be subdivided into two, an anterior group situated a finger's breadth from the labial commissure (commissural glands) between the artery and the vein, and a posterior group behind the vein, at the front of the masseter, not far removed from the meatus of Steno's duct; (3) a superior maxillary group of less frequent occurrence, consisting in glands included in the naso-labial fold on a level with the lower border of the orbit at the internal palpebral angle.

The anatomical accuracy of this distribution is confirmed by clinical observation. I have notes of seventeen observations (two of them already published by Küttner) from von Bruns' clinic; in nine of these the supra-mandibular glands were involved, and in eight the buccinator glands, the lesion being cancerous in twelve and tuberculous in the others.

As a matter of fact chronic adenitis is usually due to cancer or tuberculosis, and even acute suppurating adenitis is, in many cases, tuberculous, though sometimes consequent upon infection from carious teeth, tonsillitis, erysipelas, &c.

Out of eighty-four cases which I have found in the literature of the subject, in twenty-five the initial lesion was cancer (cancer of the nose, lower lip, cheek, temple, parotid or superior maxillary alveolus), while in fifty-nine the *point de départ* was an acute or chronic inflammatory lesion of the face. I may add that the buccinator glands were involved in forty-six (nine cancer, thirty-seven tuberculous, or simple inflammatory lesions); the supra-mandibular glands in thirty-seven (sixteen cancers, twenty-one inflammatory affections), and once the sub-orbital glands, following facial erysipelas.

These figures suffice to prove that adenitis of the cheek is not merely a pathological curiosity, and that it is worthy of being looked for even though it never results in the formation of large tumours or chains of enlarged glands, such as we meet with in the neck and submaxillary region. Cheek adenitis rarely exceeds the size of a pea, or at most of a nut. Its consistence and mobility vary according to circumstances, *e.g.*, its situation and its period of evolution. Cancerous and tuberculous glands in the cheek may remain for a long time as hard indolent nodules, perceptible on pinching up the thickness of the cheek between the fingers. To make sure of finding them when present, it is desirable to carry out the exploration with one finger inside the mouth, and in every case of epithelioma of the face this method should be resorted to, carrying the search into the submaxillary and submental zones, as well as the cheek.

Later, the tuberculous gland, sometimes also the neoplastic gland, spreads, becomes adherent, invades the skin and ulcerates. In acute adenitis the suppurating gland soon opens externally, and is accompanied by very considerable tumefaction of the cheek. These inflamed glands almost invariably open on the external surface of the cheek, and in the rare instances of an opening through the buccal mucous membrane, the glands affected are those exceptionally situated on the buccal surface of the buccinator muscle.

When it has reached this stage the diagnosis presents some difficulty. It is highly probable that many so-called scrofulous or tuberculous ulcerations of the cheek were originally of the nature of adenitis. We cannot be sure thereof unless, indeed, we discover the remains of glandular structure on the walls of the excised abscess, an observation by no means easy to make. Certain fistulæ of the cheek surrounded by a skin, dull violet in hue, and presenting a close resemblance to a tuberculous lesion, may be simply due to dental lesions, as, for example, necrosis of a stump in the upper jaw. In such event it is obvious that curettage or excision will be useless, and if the carious stump be removed the fistula will heal by itself.

The treatment of adenitis of the cheek, properly so-called, is simple enough. Adeno-phlegmons should be opened through the cheek except in the rare instances of a submucous collection of pus. If tuberculous they should be scraped or removed *in toto*. Lastly, cancerous glands should be removed at the same time as the original growth if we wish to do a complete operation, and for this purpose the exploration of the cheek should never be omitted in presence of facial epithelioma. The removal of these glands should be effected through incisions as short as possible, and made horizontally in order to avoid wounding branches of the facial artery or damaging Steno's duct.

The Out-Patient Departments.

GREAT NORTHERN CENTRAL HOSPITAL.

MEDICAL CASES

Under the care of Dr. H. W. SYERS.

Case I.—A man, æt. 55, suffering from a general eruption, especially marked on the face. The first glance at the patient gave the impression that he was suffering from variola. The forehead was covered with papules of the size, shape, and colour of those usually characteristic of small-pox. The whole body was more or less covered with similar spots, which were also well developed on both wrists. It was clear that the case was one of very severe secondary syphilis, for further examination revealed the fact that the patient was suffering from a chancre, and also that the rash was, to a certain extent, polymorphic, erythema, staining.

and some pustulation being present contemporaneously with the papular rash.

Dr. Syers observed that he had known cases in which this form of secondary syphilis had been diagnosed as small-pox. He also remarked that, in his opinion, this cutaneous syphilide was always indicative of a very severe, even malignant, clinical type of the disease. In the present case this was so, for the general health of the patient was gravely impaired, and he was much emaciated.

Case II.—A girl, æt. 17. This case was diagnosed as one of diabetes mellitus from the facial aspect and general condition of the patient. There was no obvious cause for the disease, which had manifested itself eight months previously, the symptoms first noticed being inordinate thirst and diuresis. Physical examination revealed the fact that latent phthisis was present; in the left supra-scapular region the note on percussion was high-pitched, and on auscultation a few crackles were present immediately after the patient coughed.

Dr. Syers called attention to the latency of the pulmonary condition; there was no cough or other symptom of the disease. This is not unusual in cases of diabetes. The physiognomy was strongly suggestive of diabetes, the face was thin and the features themselves sharp, the complexion rather yellow and inclined to duskiness, and there was a faint acetone odour in the breath. The muscles of the upper part of the chest were somewhat wasted, the clavicles and the ribs being unduly prominent. Dr. Syers remarked that the prognosis of the disease in young people was very unfavourable, diabetic coma nearly always supervening at a comparatively early stage of the illness.

Case III.—A middle-aged man came complaining of pain and tenderness of the soles of the feet, but worse in the left foot.

The left sole was found to be the seat of a perforating ulcer in a somewhat advanced stage; it was situated over the metatarsal bones and was as large as a half-crown. The ulcer on the right sole was in a less advanced condition. Symptoms had existed for some months before the patient was seen.

Dr. Syers pointed out that in all probability the case was one of locomotor ataxy; no knee-jerk could be elicited on either side, the pupils reacted to accommodation, but not to light, and on standing with the feet together the patient at once began to sway, and would have fallen had he not been supported. There were no lightning-pains in the limbs, and no inco-ordination of movement of the upper extremities could be made out.

BRITISH SANATORIA FOR CONSUMPTION.—XXXI.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR, ISLE OF WIGHT.

The Royal National Hospital for Consumption and Diseases of the Chest was founded mainly through the exertions of the late Dr. Arthur Hill Hassall in 1867. The original block, accommodating twelve patients, was opened in 1869. The last of the eleven blocks, of which the institution at present consists, contains rooms for twenty-one cases, and was completed in 1889. The hospital now forms an imposing series of houses, and affords accommodation for 154 patients, ninety-two bedrooms being available for men and sixty-two for women.

The hospital is admirably situated in the sheltered and beautiful Undercliff, about a mile west of Ventnor, and overlooking the English Channel. This district of the Isle of Wight has long been noted for its suitability for many chest cases, and although recent experience of sanatorium life in various parts of the British Isles has gone far to modify opinion on the special advantages of particular climates in the management of phthisical cases, it must be admitted that the Ventnor district presents not a few advantages. The hospital is well protected on the north by trees, a well-wooded slope, green sand cliffs and lofty chalk downs; it is also sheltered to some extent on the east and west, but to the south it lies open. It is only some three hundred yards from the sea, and its elevation is but eighty feet. The soil is mainly sandy. There are about twenty-two acres of ground. Generally speaking, the climatic conditions may be characterised as mild and humid, with considerable sun and a comparatively small amount of rainfall. Many find the place relaxing. Some consider the district unsatisfactory for throat cases.

The institution, although it still retains its name of "hospital," has for long occupied a prominent position among pioneers in the application of hygienic methods. As far as possible it is conducted on modern sanatorium lines. For many years great insistence has been made on open-air procedures. The hospital has been designed and constructed on the separate principle; each patient is supplied with a sleeping apartment. There are eleven blocks; most of them have been erected by private friends, and practically form separate and complete houses; each bears a distinct name, usually that of the donor or some relative whose name is associated therewith "in memoriam." All the blocks are connected by a spacious subway. Each block is well constructed of brick and stone and is slated. There is a covered verandah along the ground-floor, and covered wooden balconies to all but the topmost storeys. The patients' apartments are all on the south. The ground-floor is used for day rooms. The administrative block is No. 9, and has a large and elegant dining-hall, pleasantly decorated and well lighted, and with a convenient stage for entertainments. There is also a large orchestron and portrait of Dr. Hassall, the founder of the hospital. The men and women dine together, but at separate tables, and it is only in the dining-hall or at chapel that the sexes are supposed to have any opportunity of communication. In the grounds there is a sharply-defined dividing line. No. 9 block contains consulting rooms, dispensary, board room, medical officers' quarters and kitchen. The newest portion of the hospital is the Battenberg block, No. 11, which is thoroughly modern, with its teak floors and staircases, walls of Parian cement and rounded angles, well-designed doors and windows and wide balconies of iron sufficiently wide to allow a bed to be wheeled out on to them.

Nowadays the open-air method is strictly carried out. There are, however, elaborate arrangements for the collection of impure air and the admission of warmer air. Heating is by steam pipes and radiators. Electric lighting is employed in all parts.

The following are among the rules:—

"Patients shall rise at 8 a.m., and go to bed at 9 p.m., lights to be all extinguished half an hour after retiring.

"The hours for meals are: Breakfast, 8.30 a.m.; dinner, 1 p.m.; tea, 5 p.m.; supper, 8 p.m. These hours must be punctually observed, and no one must be absent from any meal without the sanction of the resident medical officer.

"Patients are strictly forbidden to enter public houses, or other places where intoxicating liquors are sold, or to partake of any liquor not ordered and provided by the hospital authorities. Summary dismissal will be incurred by infringement of this rule.

"Patients are prohibited from bringing into the hospital, or receiving from without, any article of food or drink.

"Smoking is permitted in the lower terraces and in the shelter provided there, also on the walks, but only at times sanctioned by the resident medical officer.

"Card-playing and gambling of every description is strictly prohibited."

Open-air treatment is systematically enforced. Strict hygienic precautions are taken; and as far as possible, the patients are instructed in the conduct of a healthy life. Baths are employed, and those in the newer blocks are good. Various drugs are employed as required. There is a good dispensary and a very capable

lady dispenser, who also acts as recorder of the meteorological observations. There is a general superintendent and a chaplain, who are non-resident, and a resident medical officer and three assistant medical officers, a matron, and staff of eighteen nurses. The honorary medical staff consists of five consulting physicians, four "physicians in London," three "physicians in Ventnor," one local surgeon, and there are also two analysts.

The institution is directed by a somewhat complicated series of committees, which meet in London and Ventnor.

The hospital opens its doors to all applicants without distinction of creed or sect. Cases are received from all parts of the United Kingdom. Over 19,000 patients have been admitted. Cases eligible for admission are those which are in an incipient or early stage of disease or arrested if in the later stages. Patients must be necessitous, and not in a position to defray the entire cost of maintenance and medical treatment, but not in receipt of parochial relief. Applicants for admission must be provided with a letter of recommendation from a governor and a medical certificate, and if admitted will be required to pay ten shillings a week. We recommend a careful study of the last, or thirty-fourth, annual report, which contains much matter of interest, including a valuable report on the mortality in England and Wales from pulmonary phthisis and other diseases of the respiratory system, by Dr. John Tatham, of the Registrar-General's Office, Somerset House. The report is well illustrated, and we commend its perusal to all medical men who desire to send cases to the Royal National at Ventnor.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JANUARY 20TH, 1904.

MR. CHIENE, President, in the Chair.

THE meeting was devoted to a discussion on the

DIAGNOSIS AND INDICATIONS FOR OPERATION IN ACUTE APPENDICITIS,

which was opened by a paper by Dr. W. RUSSELL, an abstract of which will be found on page 112.

Mr. J. M. COTTERILL, speaking from the surgical standpoint, said that the difficulty was to diagnose the exact condition of the appendix, the possibilities being so many, and often complicating one another. The three cardinal symptoms were pain, tenderness, and rigidity of the abdominal walls. Pain was usually first in the right iliac fossa, then umbilical, and in a few hours appendicular once more. Pain increasing after thirty-six hours indicated blockage, perforation or gangrene. He deprecated the use of opium; pain so severe as to require a narcotic was a reason for surgical intervention. Gradual diminution of pain generally meant improvement; its sudden disappearance, gangrene, especially if the other symptoms continued, in which case a cessation of pain was a very bad sign. Pain associated with frequency of micturition generally indicated that the appendix was in the pelvis. As to deep tenderness, care must be exercised in palpation lest rupture be caused. Rigidity of the right lower quadrant of the abdomen was usually progressive; it was not, however, a very early symptom. Spread of rigidity was a sign of peritonitis. Vomiting was a very common initial symptom; if it continued after the first twelve hours that was a bad sign. While constipation was the rule, uncontrollable diarrhœa might be met with. Along with vomiting, diarrhœa was unfavourable. If obstruction and tympanitis were present the case was usually past surgical measures. A moderate temperature of 102° or 103°, falling on the third or fourth day, was favourable; a fall with a rapid pulse was the reverse, while a high, remitting temperature usually indicated sepsis. He looked on the pulse and the nature of the vomiting as the most trustworthy signs; early rigors meant gangrene or perforation; leucocytosis was suggestive, but not conclusive. The facies was also a help. It was quite impossible to foretell rupture, since all the bad symptoms developed after and in consequence of rupture or gangrene. The chief indications for operation were: (1) fulminating cases, which, however, were rare; (2) in acute cases—vomiting after the first twelve hours, pulse of 100 or over, falling temperature without general improvement, sudden cessation of pain. Delay might be safe in cases of gradual onset, with tumour, and with slow pulse. The mortality in surgical cases was 25 per cent. The most important question was whether all cases should not be operated on within twenty-four or thirty-six hours, irrespective of their severity. This could only be decided by a statistical determination of the risks attending early operation, for which materials were as yet wanting. If the mortality was no higher than by the expectant method, then undoubtedly all cases should be treated surgically.

Dr. HALDANE discussed the medical treatment shortly. He advised calomel and salol as an intestinal antiseptic in the early stages. Leeches relieved the pain effectually, and so did hypodermic injections of strychnine.

Mr. CRAWFORD RENTON (Glasgow) divided acute appendicitis into three groups of cases:—(1) Ordinary catarrhal, unaccompanied by swelling; (2) acute cases with swelling, which might resolve or suppurate; (3) perforating cases. Catarrhal cases might about the fifth or sixth day give rise to exudation or become gangreneous, therefore the risk of this happening was greater when catarrhal cases were allowed to go over the third day. Ought this risk to be run? Personally, Mr. Renton inclined to remove the appendix early, even in catarrhal cases; if they were not seen till after the third day, failing urgent symptoms, he preferred waiting till the quiescent period. It was most important to watch the pulse and temperature, especially about the fifth and sixth day, when perforation or suppuration was most likely to occur. When a patient once had an attack of catarrhal appendicitis he thought he ought never to be allowed out of bed without being operated on. Leucocytosis he thought a valuable addition to the other signs.

Dr. JAMES RITCHIE said that, apart from cases he had had operated on, he had only had one death, so that his views as to the severity of the disease must be different from a surgeon's, who saw only the worst cases. Appendicular colic was in reality often a catarrh of the colon or cæcum. The diagnosis of appendicitis might be very easy or very difficult; it was very essential to examine the whole of the abdomen. As diagnostic difficulties, he mentioned cases of colitis, gastric catarrh with rheumatism of the abdominal parietes, and perforation of the stomach with passage of the gastric contents into the pelvis. Fulminating cases, and cases attended with sudden pain and shock, should certainly be operated on; quiescence of the symptoms was often very deceptive. Opiates ought only to be given after a definite decision as to whether or not operation was required had been come to. After recovery, if there was absolutely no tenderness remaining, he did not think operation was indicated.

Mr. CAIRD thought they could best understand the symptoms of appendicitis by comparing them with affections of other parts of the intestine. They were very much the same as that following strangulation of a knuckle of colon, involving only a part of its circumference, and not causing mechanical obstruction. In the same way other cases of appendicitis might be compared with partial occlusions of the intestine by swelling and the presence of a foreign body. In any case, whether the affection was of the appendix or of another part of the intestine, the result was a localised paralysis of the bowel which gave rise to the symptoms. The diarrhœa which was sometimes met with was comparable to that accompanying strangulated hernia, and was due to the emptying of the bowel below the lesion. Pain referred to the urethra, with

frequency of micturition, was probably as a rule reflex, though it might be due in some cases to the appendix dipping down into the pelvis. As to the question of operation, he pointed out that recovery always meant a damaged appendix, though, to be sure, dense adhesions might to some extent protect against future perforation. He gave details of several cases illustrating the principles of operation. As to the question of early operation in all attacks, the point on which information was needed was, How many patients have one attack, and no more?

Dr. Burn Murdoch gave a synopsis of the symptoms on which he relied for diagnosis, and alluded especially to the difficulty in distinguishing appendicitis from ovaritis in some cases. He thought there could be no doubt that perityphlitis and typhlitis existed. As to the indications for operation, he could only say that he had never had a case treated surgically but that he was glad afterwards for having done so, while he had often regretted delaying operation. Speaking generally, he was becoming more and more favourable to early operation as years went on. In his own experience single attacks were rare, and relapses common.

Mr. Stiles said he proposed to limit his remarks to appendicitis in children. He very seldom had operated on young patients in the intervals, for, as a rule, the first attack was very serious. His rule was always to operate in a definite acute appendicitis in a child. Fulminating and acute cases, the latter rapidly going on to suppuration, were relatively very common in children, catarrhal appendicitis being much rarer. The chief guide was *suddenness of onset*. Pain in the abdomen and vomiting, and especially persistence of vomiting, were most important indications. Next to them he placed the pulse, not so much its rate, which was usually over 120, as its character. The temperature was little guide. As to the examination of the abdomen, pain and resistance were difficult to estimate, so the examination should be carried out under an anæsthetic. The conditions usually mistaken for each other were intussusception and appendicitis, but the symptoms were really different; in intussusception the patient was quiet and happy in the intervals, but in appendicitis miserable the whole time. Examination under chloroform would never fail to reveal the tumour in intussusception, while in appendicitis fulness could usually be made out *per rectum*. In children early operation within twenty-four hours was imperative; by forty-eight hours the case was often hopeless. His rule was to operate on every case with an acute onset in which *any symptom persisted*. The disease was rare in the period of first dentition. As to differential diagnosis, the conditions which were most likely to give rise to error were peritonitis from rupture of caseous tuberculous glands, abdominal tubercle with an acute exacerbation of some kind, inflammatory conditions of the base of the right lung and pleura, pneumococcal peritonitis, and strangulation of a Meckel's diverticulum.

Dr. Affleck reminded the Society of a discussion on appendicitis which had taken place there eleven years ago. The diagnosis was not always easy; in his opinion the two principal causes of fallacy were enteric fever and tuberculous peritonitis. He had seen many cases with quite latent symptoms in which the patients had walked about for several days after the onset of symptoms. The worst case he had ever seen recover had been of this nature, the appendix being gangrenous and the abdomen full of pus at the time of the operation, which was succeeded first by pneumonia, and thereafter by general septicæmia.

Dr. Gulland referred to the value of the glycogen reaction as a guide to the occurrence of suppuration.

Dr. Russell replied to the discussion.

The Duke of Marlborough has consented to take the chair at a meeting at the West India Committee Rooms, on Tuesday, March 8th, at 3.45, when a paper, illustrated by limelight lantern, on "Tropical Diseases" will be read by Sir Patrick Manson.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Clinical Meeting held Friday, January 8th, 1904.

The President, Dr. Seymour Taylor, in the Chair.

Dr. Leonard C. Dobson showed a case of

LYMPHO-SARCOMA.

The patient, a man, æt. 44, had suffered a year from severe pains in the left occipital region, followed by enlargement of the cervical glands on the same side, those on the right side becoming enlarged some three months later. Three months after he complained of a bloody discharge from the pharynx accompanied by some "fleshy lumps," and rapidly lost weight. He attended the out-patient throat department of the hospital in November, 1903. Up to that time the glands were more than twice their present size, and he had a large, soft growth occupying the position of Luschka's tonsil, which bled profusely on examination, and broke down on the slightest pressure. There was no history of syphilis, and no other glands in the body were enlarged. The case was referred to Mr. Chisholm Williams for treatment, and under two exposures to the X-rays weekly had improved considerably. The diagnosis had at first been lymph-adenoma with lymphoid growth in the pharynx, but the fact that there were no other enlarged glands in the body, the persistent loss of weight, and the nature of the pharyngeal tumour seemed to point to lympho-sarcoma as the true solution.

Mr. E. Percy Paton considered it unfortunate, though unavoidable, that no microscopical examination had been possible to determine the nature of the growth in the pharynx. Should it be really lympho-sarcoma, it should not be forgotten that in such cases, quite apart from treatment, there was frequently great variation from time to time in the size of the growths.

Mr. G. A. Garry Simpson showed a patient in whom he had ligatured the internal saphenous vein for old-standing varix complicated by thrombosis. The vein was ligatured close to the saphenous opening, and in addition two masses of thrombosed veins were tied above and below without removal of the intervening portion. The result has been highly satisfactory.

Mr. McAdam Eccles congratulated Mr. Garry Simpson on the eminently satisfactory result in his case. He considered that in cases of venous thrombosis the vein at the actual site of the phlebitis should not be disturbed, but ligature of the internal saphena close to the saphenous opening was quite justifiable, especially with a view to the prevention of detachment and movement of clot.

Mr. E. Percy Paton thought that the course followed by Mr. Garry Simpson was clearly justified by the result.

The President showed a case of

SARCOMATOSIS CUTIS

in a man, æt. 32. The patient complained chiefly of cough, which was not accompanied by expectoration or night sweats. On further examination, tracheal stridor was noted, and the cough had the brassy character associated with pressure on the respiratory tract. On physical examination of his chest nothing further than distinct increase of the breath sounds and vocal fremitus and resonance on the right side could be detected. Laryngoscopic examination showed nothing abnormal. On the trunk numerous tumours—upwards of forty—were to be seen. They varied in size from that of a pea to that of a small orange, most being about the size of a small walnut. The smallest were not adherent to the skin, but very soon the cutaneous structures appeared to be involved, and a few of the larger had come to the surface and presented a granular dull red surface, dry and free from any exudation or discharge. The head, neck, and limbs were free from growths. The diagnosis lay between mycosis fungoides and multiple sarcoma of the skin, but in view of the fact that there has been no antecedent skin disease as, *e.g.*, eczema, Dr. Taylor was inclined to the latter opinion. No primary source other than the

probable intrathoracic new growth had been discovered.

Mr. E. PERCY PATON referred to three similar cases which he had seen. In each of these the primary growth appeared to be in the testis, and in each extraordinary rapid increase in size of the skin tumours was a marked feature.

Dr. ARTHUR WHITFIELD believed that the case was not one of mycosis fungoides. He thought it probable that the case was one of primary sarcomatosis cutis, a very rare disorder, but that all possible situations for a primary growth should nevertheless be investigated, as he remembered a case in which somewhat similar growths were proved after death to be metastases from an insignificant prostatic tumour of carcinomatous type.

The PRESIDENT showed a girl, æt. 19, who had been under his care in hospital for eight weeks. She was sent in as a case of advanced phthisis, and was extremely emaciated on admission, her weight being just over four stones. No evidence of tuberculosis or other organic affection was discovered, and the case was recognised to be one of anorexia nervosa as described and figured by Gull and others. The treatment consisted of careful dieting, at first by means of the nasal tube, as food was systematically refused, and later by giving small, easily digestible meals at frequent intervals. In addition, cod-liver oil was given in teaspoonful doses thrice daily. Improvement was steady and continuous, and when she left hospital she had improved immensely in appearance and in general strength, and had gained very considerably in weight.

Dr. RICE OXLEY referred to several similar cases which had been under his care. They were all of a distinctly "nervous" type; they all ran a long course; and in all careful dieting, together with massage and electricity, eventually effected a cure.

Dr. LEONARD C. DOBSON suggested the use of high-frequency electrical currents in the treatment of this and similar cases, especially if skilled massage were unavailable.

Mr. A. V. HAMILTON (for Mr. C. B. Keetley) showed a child with tuberculous disease of the spine, presenting two foci of disease with angular curvature—one in the cervical and the other in the dorso-lumbar region.

THE LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JANUARY 15TH, 1904.

The President, DR. P. MCBRIDE, in the Chair.

DR. W. H. KELSON showed (1) a case of deformity of fauces in a woman; (2) a case of epithelioma in the cricoid plate region in a woman, æt. 30.

Dr. A. LOGAN TURNER showed a case of affection of the palate and larynx in a man. The patient suffered from œdema and infiltration of the uvula, left half of the soft palate and left lateral wall of the pharynx. There was infiltration of the epiglottis and both arytænoid regions. He considered the condition analogous to certain cases which Sir Felix Semon had shown at the previous meeting.

The case was discussed by Dr. P. McBride, Sir Felix Semon, and Dr. Dundas Grant.

Mr. ATWOOD THORNE showed a case of malignant disease of the nose in a man, æt. 70.

Mr. H. B. ROBINSON showed (1) a case of syphilitic necrosis of the sphenoid bone; (2) a case of left abductor paralysis in a male, æt. 31; (3) a case of syphilis of the posterior part of the tongue and posterior pharyngeal wall.

Dr. L. H. PEGLER showed a case of crumpled septum in which he had erased the hard structures four years ago, and in which the intact mucous perichondrium remained unstiffened.

Mr. P. DE SANTI showed (1) a case of laryngeal vertigo; (2) a man with tertiary syphilis of the larynx causing stenosis, on whom thyrotomy had been performed four years ago with satisfactory results.

Dr. STCLAIR THOMSON showed (1) a case of complete paralysis of the left vocal cord in a woman, æt. 36; (2) and (3) cases of bleeding polypus of the septum.

Mr. H. T. BUTLIN showed a specimen of EPITHELIOMA OF THE CRICOID PLATE AND OF THE ŒSOPHAGUS removed by operation. The patient was a man, æt. 44, with a large smooth red tumour at the back of the larynx, almost confined to the left side, involving the whole of the ary-epiglottic fold, but not encroaching to any extent on the interior of the larynx. There was a very large mass of glands on the left side of the neck so intimately associated with the sterno-mastoid that their removal could only be carried out by removing almost the whole of the muscle. The disease had started ten months previously as a curious catch in speaking. For four months there was a difficulty in swallowing, and when first seen by Dr. Butlin the patient could only swallow with pain, and the voice had just become husky. The age and immense strength of the patient, and the fact that Professor Gluck's successful operations for what would have appeared to be hopeless conditions of malignant disease of throat and neck, induced him to put the matter before the patient, who decided in favour of operation. An extremely extensive operation had to be performed, necessitating removal of the whole internal jugular vein, the glands of the neck, and the whole of the sterno-mastoid muscle on that side. The patient made an excellent recovery, but within two months the disease had recurred. He had operated on another case of the same sort, but within a week the patient died suddenly from profuse hæmorrhage, probably from the carotid.

The case was discussed by Dr. McBride, Sir Felix Semon, and Dr. Watson Williams.

Mr. F. C. SHRUBSHALL (for Dr. P. Kidd) showed a patient suffering from a tuberculous outgrowth from the anterior end of the left vocal cord.

Dr. DUNDAS GRANT showed (1) a case of sessile fibromata at the anterior extremity of the left vocal cord partially removed by means of forceps and completely extirpated by the galvano-cautery; (2) a case of atrophy and collapse of alæ nasi treated by means of a subcutaneous injection of paraffin. A note of warning was sounded by some speakers as to the dangers that might accrue after the injection of paraffin; (3) photographs of a case of flat and sunken nose treated by paraffin injections.

Mr. HUNTER TOD showed a case of soft fibroma of the left vocal cord in a woman, æt. 31; (2) a case of sarcoma of the post-nasal space probably involving the ethmoidal region, with enlargement of the cervical glands on the right side in a man, æt. 51. The general expression of opinion was that operation was impracticable.

Dr. WATSON WILLIAMS showed a man, æt. 42, with an interlaryngeal new growth.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD JANUARY 15TH, 1904,

DR. PORTER PARKINSON in the Chair.

DR. ERIC PRITCHARD showed a case of transposition of the viscera in a girl, æt. 12. The heart, liver, stomach, and spleen were transposed. The child had been delicate since birth, and had at one time been treated for enlargement of the spleen, owing to the liver having been mistaken for that organ. In reply to questions, Dr. Pritchard said the girl was undoubtedly deficient mentally, and that he would have a skiagram taken to see whether the aortic arch was on the right side.

DR. PRITCHARD also showed a case of congenital absence of the left arm in a girl, æt. 15. The stump ended about two inches below the elbow in a small excrescence, which presented the appearance of a rudimentary thumb provided with a nail. He regarded the case as one of arrested growth during an early stage of development by a fibrous band which partially strangulated the growing extremity.

Dr. HAWTHORNE said that there were many cases which presented processes in the stump; he had seen at least two in which there were processes that might

be claimed to be digits. In one of these there were five processes.

Mr. A. H. TUBBY showed a case of sarcoma with secondary deposits in a boy, æt. 2¾. Seven weeks previously the child received a knock on the left leg, and soon afterwards the mother noticed a swelling there, which was poulticed. Three weeks ago he was again struck on the same leg, and also fell, striking his head. He now presented a definite tumour over the left leg, attached to the fibula, and a smaller tumour over the right parietal bone. The left inguinal and iliac glands formed a large adherent mass, but were not tender. In 1889 Mr. Tubby, in a paper published in the *Lancet*, had pointed out the direct relation of traumatism to sarcoma of bone, and he thought this was now generally accepted. The growths on the leg and head both followed a direct injury. He thought they might be looked on as separate local outbreaks of a specific disorder. The occurrence of pyrexial attacks was not unknown in cases of rapidly-growing sarcoma, and might complicate the diagnosis. He had seen a case of sarcoma of the lower end of the femur in a girl, æt. 13, where the temperature reached 102° F., and led a colleague to believe that it was a case of acute periostitis. This was disproved by incision. In the present case operative treatment was not available owing to the implication of the glands.

Mr. LOCKHART MUMMERY suggested that the primary growth might have been in the glands of the pelvis without giving any external signs.

Mr. TUBBY also showed a case of congenital dislocation of the fifth cervical vertebra in an infant of three months. The deformity was noticed the day after a normal birth. No symptoms had been observed until a week ago, when vomiting occurred several times a day. At the base of the neck there was a sharp bony prominence, which corresponded to the fifth cervical vertebra. The summit of this process was formed by the left articular process, and the spinous process could be felt to the right of it. On pharyngeal examination, a depression could be felt on the left side of the affected vertebra. There was also congenital scoliosis, the curve being to the right in the dorsal region, and to the left in the lumbar. Another congenital deformity present was the absence of the costal cartilages of the fifth to the eighth ribs on the right side of the chest. There were no evidences of paralysis. Mr. Tubby regarded the case as one of dislocation of the vertebra.

Dr. ERIC PRITCHARD showed a specimen of congenital malformation of the heart.

Dr. T. M. FORTESCUE BRICKDALE (Bristol) showed the following specimens:—(1) Two examples of congenital dilatation of the ureters and hydronephrotic kidneys, with hypertrophy of the bladder; and (2) two specimens of tuberculous ulceration of the stomach.

Dr. GEORGE CARPENTER showed a specimen of congenital cysts of the lung.

Mr. T HOWELL EVANS read a paper on the relation of

CERTAIN EXTRA- AND INTRA-CRANIAL HÆMORRHAGES IN THE NEW-BORN.

He considered that these hæmorrhages were dependent on the following factors:—(1) Irregularity in the moulding of the fœtal head; (2) this irregularity arises from the presence of accessory sutures in the situations where certain extracranial vessels anastomose with the intracranial vessels; and (3) the rise of blood pressure which occurs during the reactionary period, when the child is recovering from the birth trauma. In support of these views, he noted the facts that these hæmorrhages occur in non-instrumental labours, and as frequently in breech as in vertex presentations, and with approximately the same frequency as the accessory sutures referred to. In a normal fœtal skull the anastomosing occipital and meningeal vessels are secure from injury, but when the accessory sutures are present irregular moulding occurs at them and the vessels are lacerated. The author illustrated these anatomical irregularities and the allied conditions in anthropoid apes by a series of lantern slides.

Dr. SUTHERLAND said that this subject was of extreme interest to physicians and surgeons, and that he considered Mr. Evans' paper was a most suggestive one. They met with cases described as birth palsies, in which the labour was normal, neither too prolonged nor too rapid, and it was difficult to understand how such cases were explained by the ordinary pressure theory.

Dr. HAWTHORNE said that any theory which was to account for these cases of intracranial hæmorrhages must take cognisance of the fact that they occurred in cases which had not been subjected to any undue pressure, some cases occurring in infants born at the seventh month.

Dr. W. C. CHAFFEY (Brighton) read a paper on

THE SEQUEL OF A CASE OF EXTREME WASTING,

shown at a meeting in July last. The patient was a boy, æt. 10, who was extremely wasted, refused all solid food, but drank two and a half pints of milk daily, and presented no objective signs of cerebral disease. The case had been regarded by most of the members as one of hysteria. In October he developed bedsores, had attacks of headache with screaming, and tonic contractions appeared in the extremities. These and other symptoms led to a diagnosis of tumour cerebri or meningitis. At the necropsy there was found to be chronic meningitis, chronic hydrocephalus, and an endothelial tumour about the size of a walnut attached lightly to the posterior aspect of the right optic thalamus.

Dr. CARPENTER said he believed that not only might new growths be started by traumatism, but also other diseases, such as tuberculous meningitis, pneumonia, and pleurisy.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

AN Ordinary Meeting was held at 20 Hanover Square, W., on Wednesday, January 20th, at 8.30 p.m., the President, Dr. ALFRED STREET, in the Chair.

A paper was read and a demonstration given by Dr. W. S. HEDLEY on "Physical Therapeutics," an abstract of which will be found on page 113.

The PRESIDENT said he was particularly struck by the judicial moderation of the claims put forward, and inquired whether investigation had yet been made of the radio-activity of sea-water, and why the healing of an ulceration caused by radium sometimes took so long as six months. He asked for information as to the activity, applicability, and mode of using the plasters containing thorium and pitchblende, which were shown by Dr. Hedley.

Dr. SYMES-THOMPSON drew attention to the value of the instruments described, by which the quantity and quality of the forces evolved were estimated as likely to add greatly to the precision of X-ray therapeutics.

Dr. SANSOM narrated his experience of the high frequency current at Aix, and how a great authority there thought little of them. We ought to be very careful to differentiate between the subjective and the objective. There was much of glamour about electricity, but the radium discovery was very potent for good and taught us that there was much yet to learn.

Dr. HERSCHELL said that he could not agree with Dr. Sansom that the results of high frequency applications were mainly due to suggestion. In addition to the effect upon the metabolism of the body, which might be disputed, if we administered the current from the small solenoid with a spark gap in the circuit we should obtain muscular contractions equalling those produced by the induced current or by the Morton current. There could be no suggestion about that. The effect upon hæmorrhoids also was a visible one; if we saw a pile of an inch in diameter shrink to half the size as the result of two or three applications of a condensor electrode we must perforce credit the evidence of our own senses. And it was difficult to understand how such a result could be brought about in any other way than by the direct action of the current upon the tissues.

Dr. GROVES (Carisbrooke) said he had gathered that

the X-ray and high frequency currents were powerful and dangerous agents, about the action of which very little was actually known by some of those who practise this form of therapeutics. He thought that careful experiments should be made in public institutions by scientific men, and any positive results obtained by them given to the profession.

Dr. BRAITHWAITE wished to know whether the effect of high frequency currents in rheumatoid arthritis is due to general tonic effect on the patient or to an effect on the specific cause of rheumatoid arthritis.

Dr. SEPTIMUS SUNDERLAND asked what effect was produced on cheloid growth in scar-tissue by the X-rays, Finsen light, and radium.

Dr. Leonard Williams and Dr. Gage Brown made remarks.

In reply, Dr. HEDLEY could not refer to any experiments demonstrating the radio-activity of sea-water. He thought the ulceration produced by radio-active bodies was the same in its clinical character and pathology as that of X-ray burns. The therapeutic uses of high frequency currents had never been tested under really experimental conditions, but there was no possible doubt as to their physiological effects upon the "respiratory combustions," urine, blood, and blood pressure, &c.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT the conclusion of the annual meeting for the election of office-bearers, held in Owens College, Manchester,

Dr. A. STOKES read the notes of a case of eclampsia, with fatal result.

A discussion followed, in which the President, Drs. Briggs, Martin, Croft, Nesfield and J. Garner took part, after which Dr. STOKES replied.

Dr. A. DONALD (Manchester) read a paper on—

CHRONIC ENDOMETRITIS AND CHRONIC METRITIS IN VIRGINS.

He dealt with affections of the endometrium and mesometrium occurring apart from the usual infective causes (sepsis, gonorrhœa, &c.). The paper was based on a series of forty cases which had been carefully observed. Attention was specially directed to one group of cases, which were characterised by the association of these three conditions:—(1) Small or infantile cervix; (2) acute flexion, forwards or backwards; (3) enlargement of the uterine body. The symptoms in these cases were, in the order of frequency: (1) pain or dragging sensation in one or both iliac regions, or pain generally in the lower zone of the abdomen (in thirty-six out of forty cases); (2) dysmenorrhœa (in thirty-three out of forty cases); (3) leucorrhœa (in thirty-one out of forty cases); (4) menorrhagia or metrorrhagia (in sixteen out of forty cases); and (5) remote or nervous symptoms. In a large proportion of the cases the uterine mucosa was much thickened. The uterine cavity showed an increase in length of from a quarter to one and three-quarter inch, and the mesometrium was sometimes considerably thickened. Microscopic examination of the mucous membrane removed showed great increase in glands or in inter-glandular stroma, or both. Remarks were made as to the etiology and treatment of the condition.

The paper was discussed by Drs. Lloyd Roberts, Arnold Lee, W. E. Fothergill, Stokes, Richardson, and the President.

Dr. DONALD replied.

The list of office-bearers elected at this meeting will be found under the heading of "Medical News."

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST, JANUARY 21ST, 1904.

DR. JOHN CAMPBELL, F.R.C.S., President, in the Chair.

THE QUESTION OF SMOKING AT MEETINGS.

IT was proposed by Dr. A. B. MITCHELL, and seconded by Professor LINDSAY, that the practice of smoking at the general meetings of the Society be discontinued. After an amusing debate, in which the painful symptoms induced in some of the weaker brethren by an evening spent at a meeting where many men were smoking were vividly described, the motion was passed by a fair majority.

Dr. W. B. MCQUITLY showed a case of muscular dystrophy, and

Dr. FULLERTON an anomalous case of the same disease affecting one arm only.

Dr. ROBERT CAMPBELL showed two cases illustrating the effect of surgical treatment in obstetrical paralysis.

Dr. H. L. MCKISACK showed films from the urine of a case of tuberculosis of the kidney, showing casts of tubercle bacilli.

Dr. R. J. JOHNSTON read a paper on

NORMAL AND ABNORMAL MOBILITY OF THE KIDNEY,

based on an examination of the mobility or otherwise in a series of about 250 gynæcological cases, in which he had studied this point.

The paper, which led to an interesting discussion, will be published later.

Dr. Thos. Carnwath and Dr. Robert Watson, both of Belfast, were elected members of the Society at this meeting.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 31st, 1904.

PNEUMONIA IN CHILDREN.

NOTHING is generally more difficult, said M. Variot, than the diagnosis of pneumonia in children. The classics say that it is a rare affection, that broncho-pneumonia was more generally observed. The fact was true for broncho-pneumonia, but not absolutely exact as regarded pneumonia, which often passed unperceived.

A child, æt. 10, entered the hospital for supposed typhoid fever; high temperature, prostration, loaded tongue, diarrhœa; the symptoms were all those of typhoid. Examination of the lungs revealed sub-crepitant *râles* at the base. However, by percussion M. Variot discovered a dull zone at the apex of the right lung and behind which awakened his attention; nevertheless, the treatment ordered was that of typhoid fever: baths at 86° every three hours as long as the temperature remained above 102°, and quinine given by the mouth.

On the sixth day the fever fell suddenly, and at the same time the signs of pneumonia became evident, souffle and fine sub-crepitant *râles*.

In commenting on the case, Dr. Variot said that in such cases the signs afforded by auscultation were very uncertain; pneumonia in children attacked the centre of the lung, and as a large layer of healthy tissue separated it from the ear, nothing very abnormal could be heard. Weyle, of Lyons, claimed he had discovered a new sign of pneumonia: absence of expansion of the chest in inspiration on the affected side; but that sign was inconstant and could be found in other affections. The radioscope constituted a much better means of diagnosis, as the diseased part was represented by a shadow on the screen.

Practitioners, in presence of pneumonia in children, should eliminate from their mind, by careful and repeated percussion of the lung, the idea of typhoid fever. The same prudence should be observed with meningitis, a malady which naturally threw a family into despair. It was true that meningitis could succeed pneumonia as purulent pneumococcic meningitis, but it was a very rare affection, and was always fatal. On the other hand, pneumonia was a very benign affection in children.

Antisyphilitic Injections.

Huile grise:
Purified mercury, 40 grammes;
Lanoline (sterilised), 12 grammes;
Vaseline (sterilised), 13 grammes;
Oil of vaseline, 35 grammes.

Shake the mixture before using; two drops injected every six or eight days.

Abuse of Vaginal Injections.

Professor Lucas-Championniere has for many years protested against the abuse of vaginal injections. In a normal confinement, when the uterine wound and the vagina have been properly disinfected, further injections were needless. Ordinary leucorrhœa was not septic; it resulted only from uterine congestion, which was frequently cured by scarification of the os and the administration of iodide of potassium.

During pregnancy, vaginal injections might provoke miscarriage, while at the time of delivery the professor admitted only one injection of a strong solution of phenic acid. After delivery the patient should not be touched. In gynæcology M. Championnière criticised also the abuse of injections which irritate the nerve plexus. Among the agents used he preferred solutions of phenic acid, oxygen water (3 or 4 volumes), permanganate of potash, 1-2,000, alkaline solutions, astringents (camomile, walnut leaves, oak bark, tannin, &c.).

In the healthy woman no injection should be used; they were an obstacle to impregnation. Against leucorrhœa, alkaline injections to correct the acidity should be prescribed.

In conclusion, M. Lucas-Championnière said that vaginal injections should be regarded as a medical treatment, and never become a part of the toilette of a woman.

Anæsthesia by Cocaine and Adrenalin.

One of the most useful applications of the extract of the suprarenal capsules, says M. Foisy, consists in the possibility of obtaining anæsthesia and absence of hæmorrhage by its association with cocaine as follows:—

Solution of cocaine (1-200), 10 grammes.
Solution of hydrochl. of adrenalin (1-1,000) 10 drops.

In the case of large incisions (anthrax, suppurating adenomata) the entire following mixture may be employed:—

Solution of cocaine (1-200), 20 grammes.
Solution of adrenalin (1-1,000), 3 drops.

For a whitlow or boil:—

Solution of cocaine (1-100), 1 gramme.
Solution of adrenalin, 4 drops.

To avoid any accident it is necessary to place the patient in the horizontal position. The first injection should be made in the line of the incision and into the skin. One or two Pravaz syringes suffice. The needle is withdrawn and inserted more deeply, and three or four syringes may be necessary for the infiltration of the cellular tissue, and finally, one or two syringes are injected into the abscess.

As effect of the injection, the redness of the skin disappears very rapidly, a well-marked whiteness taking its place. In three or four minutes the anæsthesia is complete. The incision should be made layer by layer; transfixion with the bistoury should be rejected. As the incision is almost bloodless, care should be taken to ascertain if any vessel needs pinching up, otherwise secondary hæmorrhage might occur. To avoid such accidents as pallor, vertigo, or syncope it is prudent to make the patient keep the recumbent position several hours after the operation.

By anæsthesia, adds M. Foisy, obtained by this method one can operate without pain on whitlows, boils, anthrax, abscesses, anal fistula, &c.

Germany.

[from our own correspondent.]

Berlin, January 31st, 1904.

The Treatment of Epilepsy with Bromide of Sodium and Withdrawal of Chloride of Sodium.

A notice of a paper on this subject by C. Madien appears in the *Deut. med. Zeitung* of January 18th. This form of treatment has now been carried out in different institutions for two or three years, and the mode is based on the assumption adopted by Toulouse and Richet, that a much larger quantity of common salt is used than is required by the system, and that the excess prevents the due sedative action of the bromine salt so that unnecessarily large doses of the latter have to be given to produce a decided effect. It is claimed that only about two grammes of the sodium salt are required daily in place of the fourteen grammes usually made use of. In the case of twenty epileptics who, in spite of bromine treatment, had attacks almost daily, experiments were made. They each received 100 grm. milk, 300 grm. of meat, 300 grm. of potatoes, 200 grm. of flour, 2 eggs, 50 grm. of sugar, 10 of coffee, and 40 of butter. The nutrient value of the diet was 2,700 calorics. It was well borne for months. Besides this, 4 grm. (later 2) of bromide of sodium were given. It is stated that the results corresponded to the hypothesis, the attacks diminishing both in number and severity. The special diet without the bromine, however, showed no beneficial influence. Balirit also made experiments. He left out the meat, and replaced the sodium chloride of the bread by sodium bromide, a change which was well borne by the patients; 3 grm. of sodium bromide were added to 300 to 400 grm. of bread. The results in twenty-eight persons were remarkable; 86 per cent. of them lost their attacks completely, and in the remainder they were fewer and less severe.

The writer gave a modified Balirit diet—141½ litres of milk, 40 to 50 grm. of butter, 300 to 400 of bread and fruit of a nutritive value of 2,300 to 2,400 calorics. This was given to eighteen patients with slight modifications with good effects. In order to suit various appetites and to vary the dose of bromide, three sorts of bread were baked, one containing ¼ grm. of bromide to the 100 grm. of bread, one with ½ grm., and one with 1 grm. As, however, the diet could not be carried out strictly for months together, one consisting mainly of vegetables and with very little meat was adopted, and without harm to the treatment. As regarded results, a much more intensive action of the bromide was visible, a much smaller dose was required than formerly, and the undesirable bye-effects were avoided. The action on the disease also was more favourable. Patients who before had a monthly attack remained quite free after six months. He considers that the treatment, which, however, can only be properly and thoroughly carried out in an institution, has much to recommend it.

At the Medical Society, Hr. Plehn showed a case of

Leucæmia.

The patient was admitted into the City Hospital on October 30th, for a pain in the left leg that he had had for ten days. He had ascites, swelling of the liver and spleen, slight glandular enlargement, gingivitis, retinal hæmorrhage, and leucæmic changes in the blood; besides this, he had a rather large retro-peritoneal hæmaturia. After getting worse at first, he soon improved. The original myelogenous mixed-celled leucæmia improved, so that at the time only slight blood changes remained. All the changes in the organs had disappeared except a slight remaining enlargement of

the spleen. Such remissions in the course of the disease were very rare. The treatment made use of—injection of arsenic—he did not think responsible for them.

Hr. Kohn had seen such remissions twice, and did not think they were due to treatment. In one case the remission lasted six months, and then the disease proved rapidly fatal. In another case the improvement lasted ten years, but the latter was a chronic case.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 31st, 1904.

ANEURYSMA SPURIUM.

STUTZER showed pathological preparations to the Gesellschaft der Aerzte, where an exostosis from the femur led to a false diagnosis.

Wernlechner related a similar experience where a coagulum in the vessel over the exostosis compelled him to amputate the limb. In the early part of treatment the aneurysm was perfectly distinct, but when the blood coagulated in the cavity the whole vessel solidified, closing up the arterial circulation. No pulsation could be detected, and from the hardness of the neoplasm it was concluded that an osteo-sarcoma was the cause of the obliteration.

CEREBRAL ANGIO-SARCOMA.

Moszkowicz followed with a few cases of some interest to the Society. The first was a joiner, æt. 28, from whom he had removed an angio-sarcoma from the cerebrum, leaving an opening in the frontal bone of 6 by 7 centimetres, which he had covered with a celluloid plate.

He exhibited a tailor, æt. 39, whom he had resected at the first and fourth rib on the left side for peripleuritis.

He next showed a test tube for centrifugal work in securing sediment by means of attaching two drainage-tubes.

CHLOROMA.

Hitschmann reported the history of a case of chloroma affecting the skin and buccal region. From the right tonsil spread a neoplasm having all the appearance of a sarcoma. Immediately after this a few disseminated patches appeared on the body, first on the breast, next on the face, and subsequently on the extremities. These patches were of an efflorescent green colour, and were observed on the conjunctiva of the eye as well as the bulbus itself.

A careful examination of the blood showed an increase in the number of the leucocytes; at a later period lymphæmia poikilocytosis and polychromophilia.

The post-mortem revealed a large accumulation of a greenish deposit diffused over the body, which seemingly had taken its origin in the tonsils, as it was found under the mucous membrane of the fauces, nose, throat and bronchi. The glands of the neck and mediastinum were as green as grass by infiltration.

CANITIES PREMATURA ET ALOPECIA AREATA CURED BY RÖNTGEN RAYS.

Karl Ullmann showed two patients whom he had successfully treated for premature grey hair or poliosis, which is supposed to be more correctly described under the term canities, which is simply an atrophy of the hair pigment.

The first was a young man, æt. 28, who had always been healthy, but ten years ago, when only eighteen, he found himself becoming grey-haired, although the growth was of the usual or normal thickness. About the beginning of 1903 the hair began to fall out in great quantities without any attributable cause. This denudation confined itself to the middle of the head. As an experiment the Röntgen rays were applied for fifteen minutes on two occasions within a week, but to the horror of the patient this seemed to aggravate the disease, as another denudation occurred, leaving the patient's head as bare as the palm of the hand.

A few weeks after the hair had all fallen off, a fine, soft crop of black hair commenced to appear, and by June he had a profuse head of hair. Ullmann concluded that there was no doubt about the efficacy of the rays in stimulating the growth of hair as well as inducing the formation of pigment, which he endeavoured to prove by another case of alopecia areata.

BILATERAL TUBAL PREGNANCY.

Emerich Ullmann related the history of a patient, æt. 29, who on February 26th, 1903, was operated on for tubal pregnancy on the left side.

In July, 1903, symptoms again showed that tubal pregnancy had occurred on the right side. By the end of September this suspicion was confirmed and an operation performed, removing both uterus and right ovarian tube with the fœtus. The patient is now well.

GROWTHS IN FRONTAL AND MAXILLARY SINUSES.

Weil showed Röntgen photograms of the maxillary and frontal sinuses, both before and after treatment with sulphate of lead. He first fills the sinus with the powder, which prevents further thickening of the mucous membrane or increase of any growth present, which he contends is the most simple and conservative way of treating these cavities and thus obviating a radical operation.

Chiari observed that he recently treated an empyema of the maxillary sinus with an iodoform plug, with an excellent result. The progress of the disease and treatment was watched with the Röntgen rays.

ENTEROSTOMY.

Eiselsberg gave the Society a detailed history of 52 cases of lateral anastomosis of the bowel with 13 deaths; 8 of the cases were unilateral with one death; and 14 were total "Auschaltung" of the bowel with 3 deaths. Of 39 cases with lateral anastomosis 14 died within a year after the operation; 4 cases are still under observation, and two have quite disappeared. The remainder range from one to four years, three of whom were certainly carcinomatous. The operations were performed on account of neoplasms in 35 cases; acute ileus in 8 cases; tuberculosis, 21; acute appendicitis, 4; and 8 times for fistula. In summing up his results he said inoperable cases where anus præternaturalis is necessary, later entero-anastomosis is the best. It is also preferable where an antecedent operation is necessary in cases of fistula. The unilateral operation is usually more severe and more prolonged than the lateral operation, neither does it give the freedom desirable. When the bowel is fully separated most satisfaction will be obtained, although this is the longest and most severe of all the performances, but is the sovereign remedy for such affections.

In the discussion Schnitzler said that he always performed the lateral anastomosis by using one of Mosetig's double closing tubes, which was a protection for the contents of the bowel in the separated portions. He related another case of obliteration between ileum and cæcum from tuberculous ulceration. After the operation the pain was very great, which necessitated another operation to resect the obstruction which appeared to be the cause of the pain, owing to the peristaltic action dragging on the affected part. After resection the patient was quite well.

Ullmann said he had performed the total operation five times with disastrous results, not one of the patients surviving. They either died through the operation or from the disease.

Eiselsberg said he had not confirmed nor seen Mosetig's method tried on animals.

The Operating Theatres.

GUY'S HOSPITAL.

Excision of Large Vascular Tumours.—Mr. Clement Lucas operated on a female child, æt. seven months, who had been admitted for a swelling on the right side of the head. The patient was a healthy-looking baby who had enjoyed good health from its birth. When the child was born she had a red mark on the same side of the head, and in the same place. It was then as large as a sixpence; it was not raised above the skin, but the hair on it did not grow. The parents had brought her to the hospital when she was five weeks old, when the red mark was burnt out and the wound strapped up. When the strapping was removed, the place looked sore; this soreness gradually disappeared, but afterwards the place looked the same as before, and the red mark got gradually larger and became raised from the surrounding skin; it continued to swell and extend till about four months before the present time. On examination, the swelling was now about an inch and three-quarters long and an inch in breadth, and was situated over the parietal region; it was soft and fluctuating, and its edges were definite, there being a red mark in its centre; its surface was shiny and dry-looking, and no pain was felt on its being manipulated. The patient having been anæsthetised with chloroform, an elliptical incision was made surrounding the coloured area. The skin was dissected backwards for some distance on either side over the cavernous part of the nævus until well beyond its margin. In this way, there being often a kind of fibrous limitation to a cavernous nævus, fewer vessels, Mr. Lucas pointed out, are met with than if the nævus is by accident encroached upon by incision. The feeding vessels can very readily be controlled by finger pressure against the bone till their ends are secured by forceps and ligatured. The nævus being isolated on all sides was finally dissected up from its attachment to the pericranium and removed. Having completely controlled the hæmorrhage, Mr. Lucas brought together the scalp, but only with considerable difficulty, owing to the large surface removed. In order to render the scalp more movable, it was detached still further from the subjacent parts, and it was then found that with the aid of strong salmon-gut ligatures the edges could be approximated.

The second case was that of a rapidly spreading nævus of the scalp, eyelid, ear and face, where it was absolutely necessary to do something to prevent its rapid growth. The patient was a male child, æt. six months, who had been born with a red mark on its forehead about the size of a pea; the mark was situated to the right of the anterior fontanelle. It spread rapidly, soon reaching to the back of the ear and down over the right eye, on to the cheek, and also towards the nose, and across the middle line of the forehead. A place on the back started at the same time, and was at first the size of a pin's head, but this also spread rapidly, so that now it is six inches from above downwards and about five inches at its base; it is situated over the scapular region. The little patient was perfectly healthy in all other respects. In these cases Mr. Lucas relies on galvanic cautery puncture as a primary measure to prevent the spreading. The patient being under an anæsthetic, a series of deep punctures were made along the margin of the growth about an eighth of an inch apart; they were carried through the cellular tissue down to the deep fascia. Any tendency to bleed was stopped by reducing the heat of the cautery so as to make a black eschar. The apertures thus made along the margin of the growth were then filled in with iodoform powder, dry, antiseptic gauze being applied over. In this way, Mr. Lucas said, suppuration is reduced to a minimum.

He remarked that these two methods—excision and cautery—he entirely relies upon for the cure of all nævi. Although he considered the galvanic wire cautery to be the more convenient, yet a pointed Paquelin's cautery is often more easy to carry about, and when neither of these is available the homely skewer heated in the fire serves equally well for cautery puncture, or even a straight paper file will serve the purpose heated in the fire, the wooden handle of which protects the surgeon's hand from injury. He pointed out also that there was still hesitation among many in employing excisions for the very largest nævi, some of which may occupy a large part of the cellular tissue of a limb; in these cases he himself operates successively on considerable portions, leaving each successive part to heal before subjecting the patient to a second, third, fourth, or fifth operation. He mentioned a recent case which had just left the hospital, in which he excised in three operations a large subcutaneous nævus affecting the lower eyelid, nose and cheek; the first operation was carried out in a vertical direction, leaving the scar on the side of the nose; the second and third were carried out horizontally on the eyelid and cheek, so as to leave the scars corresponding to the upper margin of the superior maxilla. The result was very satisfactory, the scarring following these lines not being very noticeable, whilst, on the other hand, the nævus before removal was most disfiguring. Again, in a case which he completed last autumn, he removed by excision in seven operations an enormous nævo-lipoma of a pendulous character extending from the buttocks to the foot, completely curing the patient of a tremendous disfigurement. He remarked that the cautery was of chief use in the red capillary nævi, which are apt to spread rapidly, whereas excision is more applicable to the subcutaneous cavernous form or to the mixed form.

CHELSEA HOSPITAL FOR WOMEN.

Abdominal Hysterectomy for Myoma.—Dr. Arthur Giles operated on a single woman, æt. 30, who had been under the care of Dr. Gordon Hull. Her principal symptoms were weight in lower part of the abdomen, severe pain in the left iliac region, and irritability of the bladder, causing frequency of micturition. She was unable, in consequence of these disturbances, to follow her occupation. There had been no alteration in the characters of menstruation except that the pain on the left side was then aggravated. On examination, a hard, rounded tumour was felt, which appeared to involve the left side of the uterus; the uterine cavity was deflected towards the right. The patient was very anxious to be relieved of her tumour, and an operation was undertaken accordingly. On opening the abdomen it was found that the tumour originated in the left cornu of the uterus, displacing the left Fallopian tube to a considerable extent. It was the size of a large orange. The rest of the uterus was not affected, and the right tube and ovary were normal. A supra-vaginal hysterectomy was performed. The operation presented no special difficulties, and the abdominal wound was closed in the usual way. Dr. Giles remarked that pain was not a conspicuous symptom of uterine fibroids; when present it was due either to pressure or to some complication, such as

localised peritonitis or disease of the appendages. In this case the pain was due to compression of the left ovary between the tumour and the wall of the pelvis. The bladder irritation arose from the fact that the tumour had developed anteriorly as well as laterally. It was a case in which the choice in the matter of operation lay between hysterectomy and myomectomy. The latter procedure was best adapted for tumours situated on the anterior or posterior walls of the uterus; it was not usually suitable for tumours arising in the cornua, because removal of a tumour in this position left the uterus greatly distorted. On this account hysterectomy was performed in this case. It had been shown by the statistics of a former registrar, Dr. Crewdson Thomas, that there was a very definite advantage obtained by leaving one or both ovaries in a young woman, as the disadvantages of an artificial menopause were thereby lessened. In the case of a patient, æt. 45 or more, the removal of both ovaries made comparatively but little difference in the convalescence. In the present instance it was possible to leave the right ovary. The left appendages, although healthy, had to be removed owing to their position, as they virtually arose from the tumour.

The patient made an uneventful recovery, and left the hospital on the seventeenth day after operation.

WEDNESDAY, FEBRUARY 3, 1904.

RADIUM AND CANCER.

THE importation of radio-active forces into modern medicine constitutes one of the most recent as well as one of the most fascinating chapters of modern science. The discovery of the Röntgen rays placed in the hands of surgeons and of physicians a powerful additional weapon of exact diagnosis. Before long it was discovered that the emanations from the active Crookes' tube used to produce the X-rays were possessed of therapeutic properties. So far as malignant growths are concerned exposures to the live focus tubes are found to promote healing of ulcerating carcinomatous surfaces and to relieve pain, although they do not cure the disease. Applied to recurrent nodules after operation numerous cases have been recorded in which the secondary local recurrences have disappeared and sometimes been warded off indefinitely. Many cures of superficial epitheliomata have been reported, as well as of rodent ulcers. The usefulness of the X-ray tube in malignant growths, then, appears to be distinctly limited. A field of richer promise, however, is to be found in radium, that wonderful radio-active substance whose therapeutic properties, as yet in their infancy, are being investigated by many eager inquirers in various parts of the world. A few weeks since news came from Vienna that an epithelioma inside the cheek had been cured by the application of radium. Before that time, so long back, indeed, as May, 1903, brilliant results had been attained in our own country by Mr. Mackenzie Davidson, the well-known inventor of an exact system of X-ray localisation. In the year mentioned, by the application of radium he succeeded in curing several cases. The first, one of external rodent ulcer of the nose, healed up in about a couple of months, and showed no signs of recurrence five months later. The second case was a patch, the size of a sixpence, of verrucose tuberculosis of the skin of the hand. The lesion disappeared after seven applications of radium, and with one slight recurrence was completely cured. The third patient suffered from "rodent cancer" of the nose, and was cured with nine applications. The most brilliant of Mr. Davidson's cases was that of an extensive epithelioma of the face. The whole of one cheek was destroyed, the tongue and teeth being bare, the lips partially gone, the tongue foul and discharging, the hard and soft palates invaded. After several months' treatment, the discharge has been rendered inoffensive and sterile, speech has been recovered, and extensive cicatrisation has taken place. The patient appeared to be on the high road to recovery, but in any event it is clear that the course of the epitheliomatous process was profoundly modified, if not finally arrested. That result is sufficiently encouraging to instil fresh hopefulness into the energy of the many workers who are in quest of the key to that most baffling of all medical problems, namely, the etiology and the cure of malignant new growths. One suggestion thrown out by Mr. Mackenzie Davidson is worthy of careful consideration. Twice during the treatment of the last mentioned of the above cases a more than usually prolonged application of the radium was followed by a kind of erysipelatous rash, and a "reaction" temperature running up as high as 105° F. In the remission following each of these reactionary periods there was a distinct improvement of the local condition. Mr. Davidson, in an article published in the *British Medical Journal*, observes:—"It seems fairly clear that the radium radiations produce profound changes in rodent cancer, and that absorption of the altered products leads to the blush that so often follows the application of radium in this disease; and, if the exposure has been too long, then the blush may be succeeded by a severe inflammation resembling erysipelas. There seems a possibility that the products

absorbed may act as antitoxins. There is no evidence, meantime, that this is so. It is obvious that with a large surface care must be taken not to over-expose the parts to radium, otherwise serious constitutional disturbances may be produced." Radium appears to have little or no effect when applied to carcinoma through the unbroken skin. That it is capable of exercising a profound effect upon some of the morbid cell processes in malignant neoplasms can no longer be doubted. Modern science travels fast, and it may reasonably be hoped that the glimmering nescience of to-day will be replaced by the brilliant and adequate knowledge of to-morrow. Meanwhile the thanks of the community are due to the patient and devoted labours of those who, like Mr. Mackenzie Davidson, throw the search-light of scientific method into the dark recesses of the unknown.

THE PRODROMATA OF THE PSYCHOSES AND THEIR MEANING.

To the psychiatrist and neurologist, as well as to the general practitioner, any authoritative statement bringing fresh evidence in support of ascertained facts on psychiatry cannot fail to be welcome. The importance of a knowledge of the prodromata of so serious an event as an attack of insanity cannot be too assiduously pointed out. This we are constantly reminded of by the asylum physician, as doubtless in numerous cases which finally find their way to our asylums, if the recognition and importance of the prodromata were sufficiently recognised, the mental attack might often be prevented. A most interesting and important paper by Dr. Clouston was read on this subject at the last meeting of the Scottish Division of the Medico-Psychological Association, in which the author urges the importance of recognising that attacks of mental disease have early symptoms which are often not mental in character; and that it is equally true that in neurology the fact has not attracted sufficient attention; that all sorts of sensory, vasomotor and motor symptoms may be the mere preludes to an attack of insanity and not of themselves the real disease. He also points out that the neurologist who is called in to see a woman suffering from an unusual form of headache, with anorexia, insomnia, and obscure paræsthetic sensations, often misses the real point of the case because he does not realise that such symptoms are, in this particular patient, higher-cortical in origin, and may mean an attack of acute mania in a week, if nothing can be done to arrest their course. Discussing sensory symptoms, he holds that in addition to the various forms of headaches which are most commonly met with among women, there are other sensory symptoms of pain or of paræsthesia not confined to the head, namely, spinal pains and visceral pains, which frequently precede attacks of insanity; also that the sensory prodromata of mental disease may take the form of disturbance of special sense functions, which he attributes to a failure of nutritive and dynamic energising of the higher cortical cells. If the sensory system is hereditarily weak, or exhausted, or starved, or poisoned, then the mental centres that it keeps going must soon exhibit disturbance. Hence the common sequence of sensory neuroses and melancholia. Among the motor disturbances discussed are general convulsions, followed by attacks of acute insanity; localised twitchings are common, but the most marked and characteristic motor prodromata of insanity consist of changes in the facial and eye expressions. Among the other disturbances enumerated are insomnia, circulatory, nutritive and digestive disturbances, and menstrual derangements, and Dr. Clouston contends that a general consideration of the character and frequency of such facts from the physiological and pathological, as well as from the clinical, point of view leads to the inevitable conclusion that an attack of mental disease is commonly not a simple or localised phenomenon, but that they show the solidarity of action of the whole brain and of the whole of the nerve centres in the cord, and the special ganglia of the organic systems of the body, that they seem to point to the fact that the lower parts of the sensory apparatus very often break down before the mental apparatus in the highest regions, and prove the mental cortex to be the centre of the organism and teleologically its end, and that the whole class of "mental disease" should be regarded and treated, not as local disturbances, but as widespread departures from the normal physiological condition of the whole organism. Space fails us in referring further to Dr. Clouston's paper, which contains many other interesting points not here touched on. It gives a fresh impetus to the study of the pathology of mental disease, and demonstrates the importance of a careful study of all the organs as well as the brain and spinal cord, and also of bacteriology, in connection with mental disease. Dr. Clouston has on many former occasions emphasised the relation of phthisis and other physical diseases to insanity, and there is no doubt that certain disturbances of one or other of the systems mentioned by Dr. Clouston, most frequently the alimentary, exist prior to the development of the mental symptoms, although often most difficult to elicit, as the relatives and even the family physician constantly incline to view the mental as wholly apart from any physical symptoms the patient may have exhibited prior to the development of mental symptoms.

TUBERCULOSIS IN IRELAND.

It has nowadays become a truism that the battle with consumption is one quite as much for the layman as for the medical man. The function of the latter is chiefly advisory, both as regards his particular patient, and more generally as regards the health of the community. It is the physician's duty to instruct the public in

hygienic matters, and in the case of tuberculosis, at any rate, it is satisfactory that the intelligent interest of the public has been aroused. Under the circumstances the struggle against the disease has become a prolonged campaign, and, as often happens when but little apparent progress is being made, a certain weariness of conflict appears. So much is being said and written, both in lay and medical papers, that it is often with something approaching a sense of duty rather than real interest one returns to the subject. This being so, it is with a peculiar pleasure that one finds any contribution to the literature, where either through intrinsic importance of the views held, or because of some freshness of utterance, the reader is at once interested in spite of himself. On both these points we commend the paper contributed to the current number of *Tuberculosis*, by Dr. Alfred Boyd, the Honorary Secretary of the Dublin Branch of the National Association for the Prevention of Tuberculosis. In discussing the present position of the problem in Ireland, he states, as tersely as it is possible to do, the facts and figures of the past few years, contrasting the rates of incidence and mortality with those of England and Scotland. It is discouraging to those particularly interested in the Irish aspect of the question to find that while the death-rates from tuberculous diseases in England and Scotland have during the past forty years been reduced by about one-half and one-third respectively, the death-rate in Ireland shows a slight increase. It is curious that whereas the Irish rate is now the highest, in 1864 it was by far the lowest. In an agricultural population, such as in the main is that of Ireland, it ought to be easier to arrange life on hygienic principles than in an industrial population. But we must bear in mind the fact that in the Irish peasant's cabin over-crowding is the rule, and ventilation, once the door has been shut for the night, is unknown. If anything will counteract the evils of such habits, and tend to ameliorate the sanitary conditions of the people, it is the persistence of such efforts as Dr. Boyd tells us are now being made under the auspices of his Branch. "Much is being done to educate the people in matters of general hygiene. This subject is now taught in the Roman Catholic Theological College at Maynooth, and in several of the Training Colleges for National School Teachers; the influence of such teaching on the students in these colleges should in time show itself in an improvement in the hygienic state of the towns and villages, in the life of which the clergy and teachers are so important a factor. Hygiene is also being taught by the itinerant lecturers under the Technical Instruction branch of the Department of Agriculture and Technical Instruction." As regards the treatment of the disease itself, we find that in seventy-two Union infirmaries—nearly half the total number—there is now separate accommodation for cases of consumption, and it is likely that much greater enterprise will soon be shown by the Poor-law authorities. In Dublin itself, much remains to be done. The question of making phthisis a notifiable disease is still under discussion, and though it has been stated that it is at present optionally notifiable, no step has ever been taken by the sanitary authority to invite the co-operation of the profession in Dublin. No attempts are made to prevent spitting in the streets, and but little in public conveyances. The Medical Officer of Health has again and again urged the advisability of providing bacteriological examination at public expense, but the Corporation remains inert. The existing institutions for the treatment of consumption in Dublin, while doing admirable work as far as their resources permit, are quite insufficient. In fact, for the very poor there is at present practically no provision outside the Union infirmaries. While the position in Ireland is still very grave, yet there are undoubted hopeful signs in the awakening of public opinion and the enlightened action of many public bodies. With determined reform along the lines laid down by Dr. Boyd, there is no reason why the death-rate from tuberculosis in Ireland should not be materially reduced in the next few years.

Notes on Current Topics.

St. Bartholomew's Hospital.

THE meeting of the Governors of St. Bartholomew's Hospital at the Mansion House last week in furtherance of the appeal for funds for rebuilding on the present site resulted in a preliminary subscription list of £40,000. There is reason for congratulation on this result, as showing the practical sympathy of the public for this ancient and noble charity. At the same time it cannot be said that any of the speeches advanced any conclusive grounds against the adoption of a partial removal scheme, whereby the necessity of an appeal to the public would have been rendered unnecessary. The sale of the present site would have enabled the authorities concerned to have built a palatial hospital in a healthy suburb, and at the same time to have left behind ample out-patient, casualty, and medical school accommodation. The arguments advanced by speakers were founded mainly on sentiment. Sir Trevor Lawrence remarked that removal would not only make a great difficulty in the treatment of patients, but it would absolutely destroy the medical school. Why it should be more difficult to treat a sick patient at Hampstead, say, than in Smithfield is not clear, remembering that the great majority of St. Bartholomew's patients are drawn from the provinces and from outlying London. If the medical school be threatened by removal of the hospital wards, it is well to bear in mind the infinitely greater jeopardy arising from the centralising proposals of the University of London. The Bishop of London observed that the proposal to remove the hospital would be supported by some people just as would a similar suggestion with regard to St. Paul's Cathedral. The analogy, however, is hardly sound. St. Paul's is built for healthy citizens, and St. Bartholomew's for the sick and ailing. Moreover,

many City churches are deserted, and have plainly outlived their function, while others have been removed into the country. In short, the Bishop could not have advanced an apter illustration of the desirability of sacrificing sentiment to reason as regards the retention of effete institutions on the site of their former usefulness instead of removing them to fresh centres of activity. Mr. John Tweedy said removal of St. Bartholomew's would be not only a calamity but a disgrace to the City of London. Dr. Gee argued that if the Governors listened to critics who put forward ignorant schemes the result would be the disintegration and destruction of the Hospital. We venture to think, however, that strong expressions of opinion of that kind cannot take the place of convincing argument in so important a matter. Several London daily newspapers have made a strong stand in favour of a more economical scheme of partial removal. Some pointed questions bearing upon the point were raised by a Governor, and inadequately answered.

Notifications and Erroneous Diagnoses.

The action recently tried before Mr. Justice Grantham, in which Dr. William Gould was sued for damages for certifying a child as having small-pox, when it was really suffering from chicken-pox, should encourage practitioners to have the courage of their opinions. The plaintiff was a dressmaker and she claimed that her business had been ruined by the report that she had had a case of small-pox in the house. No one can help sympathising with a person placed in this unfortunate position, but the blame must be placed on the state of the law and an unhappy conjunction of circumstances, not on the doctor. Dr. Gould is to be heartily congratulated on having come scathless out of the trial, and secured a verdict exonerating him from any suspicion of blame. We are all fallible, and the power of making a correct diagnosis does not always lie within human capacity; the best a man can do is to arrive at the decision that seems to best accord with the phenomena that he observes. Having done this, he has no option in the case of infectious disease; he is bound to notify the case, whether he wishes to or not. The responsibility entailed by his decision passes out of his hands. In the case under notice Dr. Gould admitted in his pleadings that his diagnosis had not been confirmed by the subsequent progress of the case, but that he had performed his duty when he informed the sanitary authorities of his diagnosis. A medical man in one of the large towns was lately prosecuted and fined for failing to notify a case of infectious disease with regard to which he denied that he had made up his mind, but of which he had spoken to the relatives as being possibly one of scarlet fever. With the hard legal obligation laid on him the practitioner has no alternative but to notify to the best of his ability, and it will be well for people to grasp the fact that it is they who make the laws of the land, and that any disabilities that they suffer through its being carried into effect, however hardly they may press in individual cases, are such as they themselves are responsible for. There will always be grit in the axles of the best-oiled wheels, but the coach must be driven on nevertheless.

The Late Dr. George Salmon.

In common with our fellows in other fields of science and learning, we this week deplore the death of Dr. George Salmon, Provost of Trinity College, Dublin. To few men has it been given to make a world-wide reputation in two such distinct branches of study as mathematics and divinity, yet of Salmon this may truly be said. It is a great deal more than a generation ago since his publication of "Conic Sections" raised him at once to the foremost rank of mathematicians, where he established himself permanently by other works which soon followed—"Higher Algebra," "Higher Plane Curves," "Analytical Geometry of Three Dimensions." These books were at once recognised as epoch-making in higher mathematics, and were translated into every European language. It is passing curious that as text-books they are still, after forty years, in universal use. For the past fifteen years he had ruled over his College, where he had been regarded almost with reverence by those under his sway. Of unfailing courtesy, of delicious humour, of massive learning, of incredible modesty, and withal one of the strongest of men in character and will, he had these traits that ensure both respect and love. His loss to Dublin University is incalculable, for never in her history were calm judgment and inflexible strength such as his more necessary. To our own profession he was bound by warm ties, not only as the head of a College possessing a great medical school, but by his accepting a few years ago the Honorary Fellowship of the Royal College of Physicians in Ireland.

Cancer and Morphology.

The recent researches which have been undertaken in connection with cancer have resulted in the discovery of cancer cells in fish. It is not so very long ago that a distinguished pathologist asserted that the disease was peculiar to the human species, an assertion shortly afterwards discredited by the results of a careful inquiry into the occurrence of cancer in the lower animals, which results have now been supplemented by the present discovery. This, while it does not, so far as can be seen, enlarge the scope for treatment, seems to throw some light upon the morphology of the disease, and tends rather to support the view which has from time to time been expressed that certain embryonic cells possess spermatic properties. Haeckel's pronouncement that the individual in his life epitomises the "form-modifications" undergone by the successive ancestors of the species in the course of their historic evolution, may be held to explain the genesis of those cells. If the latter are remnants of bygone ages, it is not unreasonable to anticipate that with the increase of medical

science and the consequent preservation of the physically unfit, in defiance of the law which leads to the advancement of all organic beings, namely, "To multiply, vary, and let the strongest live and the weakest die," there will be a still further increase in the number of cancer cases. It may, however, be that the improved conditions under which we live will result in such a strengthening of the resistance of the tissues that the parasitic cell can no longer make encroachments upon them. Prof. Roswell Park, of New York, stated five years ago that the death-rate from cancer was increasing at such a pace that if for the next ten years the relative death-rates were maintained, in 1909 there would be more deaths in the State of New York from cancer alone than from consumption, small-pox, and typhoid fever combined.

Gonorrhœal Infection in the Female.

A SOMEWHAT unsavoury, but nevertheless highly important point has been brought forward by Dr. Antin, of Guatemala, who, as Government examiner of prostitutes, has gained a wide experience of venereal disease in Central America. It has always been assumed and taught that gonorrhœal infection was conveyed to the female by the introduction of the gonococcal pus into the vagina, and that the first symptoms of the disease occurred in connection with that tube. The vaginitis thus initiated, one has been accustomed to think, spread to the urethra and vulva, and, if not cured by strong and early measures, to the uterus. The disastrous results of gonorrhœal endometritis and its intractable nature are too well known to need comment. But Dr. Antin holds that the primary infection occurs in the cervix uteri, and that it is only when this structure has become inflamed that the vagina suffers, the discharge passing into it from the external os. Dr. Antin first noticed that all women with vaginitis and urethritis suffered also from cervical inflammation, and subsequently his attention was drawn to the fact that many women who were quarantined for cervical endometritis developed vaginitis and urethritis later. He then took to examining the discharge from the cervix in such cases, and found the gonococcus of Neisser both by staining and culture. His final observations were made on 154 women suffering from first attacks, and in all these he found the specific organism. The therapeutical deduction from these facts is that our recognised systems of treatment have been far from sufficient, and as the early treatment of the affection—which, unfortunately, is far from being confined to the class of women of whom Dr. Antin treats—is of the greatest moment, it will be well in the future to examine the cervix carefully. It is generally admitted now that unless energetic and severe measures are adopted at the outset, very grave complications may follow, and that to treat gonorrhœal vaginitis with mild antiseptic irrigations is to play with the fire. The best method is to anæsthetise the patient and apply strong antiseptics directly to the inflamed parts, and in all future dealings the cervix must be thoroughly dealt with in the same manner if an early and complete cure is to be effected.

Pulmonary Œdema and Serum Injections.

A CHRONIC condition of œdema at the bases of the lungs is one encountered in the course of many affections, accompanied by long-continued pulmonary congestion of cardiac insufficiency, notably in chronic renal disease, when the heart has begun to fail. The occurrence of an acute œdema of the lungs is less often met with, and fortunately, for it is a very grave condition. MM. Achard and Paisseau, at a recent meeting of the Société Médicale des Hôpitaux, described an autopsy they had performed in such a case. The patient was a woman who had undergone an operation for hysterectomy, and secondary internal hæmorrhage had supervened. In order to combat this, a subcutaneous injection of normal saline solution was given, the total amount of fluid inserted beneath the skin being ten litres in the course of twenty-four hours. Signs of pulmonary œdema began to appear to which she ultimately succumbed, and the characteristic lesions were found in the lungs after death. There were, in addition, alterations in the epithelial cells lining the renal tubules. To what the real cause of the pulmonary œdema was due in this case is a matter of some uncertainty. The authors were inclined to attribute it not so much to the chloride of sodium in the injection, as to its mere bulk. Alterations in the renal epithelium have been produced experimentally by the subcutaneous injection of saline solution in rabbits, but whether a condition of pulmonary œdema might be similarly caused is still undetermined. It is conceivable that danger might arise from the use of solutions of unequal tonicity to that of the blood, and still grosser errors, such as the injection of air when the fluid is introduced directly into the circulation, have, as is well known, been attended with fatal results. The case, such as the one quoted, shows that, beneficial as serum injections generally are, some caution, at least, is required in their use.

Typhoid Fever among the Chinese.

AMONG the various external factors which influence the incidence and character of disease, none, perhaps, are so interesting or so little understood as topographical conditions. Climate, race, and national habits and customs are known to render in the same malady certain symptoms prominent, and to obscure others. Typhoid fever is a disease which is powerfully affected by locality. Mr. James Cantlie (*a*) has shown that in China its type differs somewhat from that seen in Western countries. Taken on the whole, the disease is not common among the Chinese, but, owing to the absence of accurate statistics extending over a sufficiently long period, actual figures are difficult to procure. The Chinese method of preparing food would seem to be responsible for the comparative immunity which they enjoy from

(*a*) *Practitioner*, January, 1904.

enteric fever. Practically all the water consumed by them is boiled before drinking, either in the form of tea or in the shape of congee-water, which is water in which rice has been boiled. Vegetables are invariably cooked, and little milk is drunk. It is seen, therefore, that the most important channels of infection of the disease are eliminated. Europeans appear to contract typhoid in China with greater relative frequency, perhaps because they do not always adopt the native methods of preparing and cooking food. On the other hand, the case-mortality is much higher among the Chinese than among Europeans, but, here again, difficulties arise through lack of statistics. The reports of the different missionary societies deal less with medical cases, as a rule, than with surgery and ophthalmology, as the natives seem to prefer their own doctors for ordinary medical complaints. The "typhoid state" is said to be rarely seen in the Chinese, and real epidemic forms of the disease are almost unknown, though sporadic cases occur from time to time.

The Risks of Gastric Inflation.

The simplest form of intra-gastric technique, and, next to lavage, the one earliest learnt by the student of medicine, is that of artificially inflating the stomach with gas in order to delimit its boundaries or to demonstrate the position or immobility of a suspected tumour. No special apparatus is required for this purpose, all that is necessary being the administration of a measured quantity of bicarbonate of soda followed by some vegetable acid salt, such as the tartrate of potassium. The effects can be then carefully watched, and the position of the stomach accurately noted. As a general rule the method is devoid of pain or inconvenience to the patient, and is frequently of great assistance in arriving at a correct diagnosis of certain morbid conditions of the organ. That the practice of inflation may not be altogether without danger is shown by Dr. Moses Behrend, (*a*) of Philadelphia, who relates three cases in which its performance was followed by death. All the patients were over fifty years of age. The first died from hæmorrhage, a chronic gastric ulcer being found at the autopsy. In the second case, one of carcinoma of the lower end of the œsophagus and cardiac end of the stomach, death resulted from prostration, while in the third instance the fatal issue was directly attributable to shock, great dilatation of the lower part of the œsophagus being discovered at the post-mortem. In all cases carbonic acid gas was employed in the usual manner, and each one complained of a sense of oppression shortly afterwards. One striking point is the great diversity of the lesions discovered after death, but it is noteworthy that in two cases there was disease affecting the lower end of the œsophagus and cardiac extremity of the stomach, which would thus appear to constitute a "dangerous area." The chief drawback to inflation in gastric disorders is the inability to regulate exactly the amount and tension of the evolved gas. In advanced disease and debilitated subjects its practice is certainly contra-indicated.

(*a*) *Med. News*, December 19th, 1903.

The Health of Hospital Residents.

The state of the general health of the resident staffs in our hospitals is well known to be liable to considerable deterioration during their term of office, unless special precautions are taken to avoid it. There are many causes which combine to make it difficult for a resident medical officer or house-surgeon to keep himself thoroughly "fit." The sense of responsibility, which is apt to weigh unduly upon the newly-appointed resident, the constant contact with disease, both in the wards and in the out-patient department, the disturbed rest at night, and the limited amount of open-air recreation, all conspire to undermine the health of any but the most robust. In nine cases out of ten it is the resident himself who is to blame by deliberate neglect of regular, if brief, daily exercise in the open air, for there is nothing like complete absence from the scenes of work to remove the feeling of being always on duty which is apt to develop into a veritable fixed idea. There is more excuse, perhaps, for laxity in this respect in the case of the smaller hospitals, where the resident staff is limited to one or two, but in every large institution with a medical school attached it is quite possible for those holding house appointments to get "off-time" daily, except under circumstances of great pressure. Some interesting statistics bearing on the subject have been brought to light by Dr. W. R. S. Emerson, of the Boston City Hospital, in which it is clearly seen that the health and general fitness of the resident bear a distinct relationship to the amount of exercise taken. Tonsillitis, or "hospital sore throat," was the most common ailment on both the medical and surgical side, while influenza, furunculosis, and septic complaints added their quota to the list of minor illnesses. Since the introduction of the gymnasium and the swimming-bath as part of the residential equipment of hospital colleges, the health of house-officers has materially improved, and for their own sake, as well as that of their patients, it behoves them to use the opportunities provided for systematic recreation.

The Teaching of Hygiene and Temperance.

We have received a copy of a petition which is being sent to the registered medical practitioners of Great Britain and Ireland for signature, and which deals with a matter of considerable practical importance to the State in general, as well as of deep interest and concern to the medical profession. The object of the petition is to endeavour to secure that every child in our national schools shall obtain some instruction in the rudiments of the simpler rules of health and temperance. The petition draws attention to the great importance of such instruction as a means of leading children to appreciate at their true value cleanli-

ness, personal hygiene, food, drink, &c. It also draws attention to what is being already done in this direction in the Army schools, in many of the colonies, and in the United States, as well as in some schools in Great Britain and Ireland. In the opinion of the promoters of the petition, such instruction should be compulsory and given by competent teachers, who must have themselves received adequate instruction in these subjects. THE MEDICAL PRESS AND CIRCULAR has ever striven hard to impress on its readers the necessity for every medical man endeavouring by precept and example to inculcate among his patients and the public generally the principles of hygiene. At the present time, when so much attention has been drawn to the necessity for the improvement of the national physique, the circulation of the petition is especially wise, and we trust that every member of the profession who has not already done so will add his name to those already at its foot.

Pulmonary Osteopathies

THE association of clubbing of the finger-tips with chronic pulmonary congestion has long been known, so that the possibility of similar changes from the same cause on a more extensive scale excites interest rather than surprise. According to Dr. H. E. Symes-Thompson, (*a*) the salient feature of this "hypertrophic pulmonary osteo-arthropathy" is more or less symmetrical enlargement of the bones and joints, and sometimes also of the soft parts, more particularly in the extremities. The pathological anatomy of this curious constitutional disturbance is of less immediate general interest than its causation, and it happens that this is largely a matter of hypothesis. It is said to be commoner in males than in females, and is more frequently met with between thirty and forty years of age. Although in the majority of instances the affection was consequent upon chronic suppuration in the chest, it is sometimes met with in association with other protracted morbid states, as, for instance, in congenital heart disease. It is surmised that the changes in the osseous system and joints are brought about by the presence in the blood of certain undefined toxins, some of which are fixed and others volatile. The latter should normally be got rid of through the lungs, the fixed toxins being destroyed by the liver. If this hypothesis be correct, it follows that the presence of a toxic focus in the lungs is not essential to the production of osteopathy. Many obscure points remain to be worked out before we can hope to grasp the pathology of these far-reaching changes, and the author deserves praise for his courage in tackling a problem presenting so much difficulty. As was pointed out in the discussion to which Dr. Symes-Thompson's paper gave rise, these changes are not always, or even often, met with in association with chronic pulmonary disease, so that there must be some independent factor to explain their incidence. Various forms of chronic intoxication have been invoked to explain the lesions of that ill-understood group of lesions known *en bloc* as rheumatoid arthritis, and intoxication of pulmonary origin may in certain subjects be the determining factor.

Royal Medical and Chirurgical Society, January 12th, 1904.

Tuberculous Infection of the Tonsils.

THE importance of the lymphoid tissue of the pharnyx and adjacent regions as a possible channel of infection by means of which the tubercle bacillus gains access to the system, can hardly be over-estimated. The early eradication of adenoid vegetations in young children is freely justified when viewed from this standpoint alone. The peculiar susceptibility of the tonsils in this respect is especially noteworthy, as experimental observation has abundantly proved their capability to act as channels of infection, not only for the ordinary septic organisms, but also for pathogenic ones, including the tubercle bacillus. Primary tuberculosis of the tonsils unassociated with lesions elsewhere, is exceedingly rare, as has been pointed out by Koplik, (*a*) of New York, but the same observer considers that the tonsil may be the seat of infection in certain cases of tuberculosis of the cervical lymphatic glands. Dr. George B. Wood, (*b*) of the University of Pennsylvania, has collected 1,354 cases from the literature in which the tonsils were examined for primary tuberculosis, with the result that positive data were obtained in seventy-three—*i.e.*, in 5·4 per cent. Secondary tuberculosis is somewhat more frequent, and the opinion of Schlesinger is quoted to the effect that in pulmonary phthisis tuberculosis of the tonsils is almost always co-existent. The presence of the latter can, as a rule, only be detected by microscopic examination, as the deposits of tuberculous material is situated deeply in the tonsillar substance. One clinical proof of importance is always brought forward, namely, that in tuberculous cervical adenitis the posterior submaxillary is generally the first gland to be affected, and as the efferent lymph-vessels of the tonsil lead into this gland anatomical evidence of the continuity of the path of infection is thereby furnished.

Irish Maternity Hospitals and the Midwives Act.

WE are pleased to learn that the representatives of the Belfast Maternity Hospital have joined in the protest of the Dublin Hospital against the extraordinary regulations which have been adopted by the Central Midwives Board, with the result of rendering every Irish trained nurse ineligible to offer herself for examination and certification in England. At a meeting of the staff of the Belfast Maternity Hospital, the following resolution was adopted and entrusted to Professor Byers for presentation to the President of the Central Midwives Board. "That the Central Midwives Board be requested to alter their rules so that any woman attending 'The Incorporated Belfast Maternity Hospital' shall be deemed to have complied with

their regulations in reference to the training of hospital midwives, and shall be eligible to present herself for the examination of the Central Midwives Board." This resolution has been somewhat loosely drafted, but its meaning is nevertheless clear. It cannot be expected that every woman "attending" a midwifery hospital can be regarded as having received a suitable training, it is the woman who has taken her full course at the hospital and passed the examination held by the staff who can claim the right, and whose claim must be granted. We cannot help thinking that the Central Midwives Board must be very nearly on the point of recognising that it has placed itself in an impossible position by recognising midwife-trained nurses, while at the same time automatically excluding every nurse trained in the great Irish maternity hospitals.

Scarlet Fever Prevalence and Isolation.

The relationship between modern preventive medicine and infectious diseases is one of the most important of scientific problems. In every communicable disease the application of sanitary measures of notification, isolation, and disinfection have been followed by a satisfactory lessening of incidence. In scarlet fever, however, the disease not only holds its own, but appears to gather in strength in spite of all the efforts of sanitarians. It becomes necessary, therefore, to search out diligently for the weak spots in the armour, for the control of scarlet fever is certainly within the compass of modern preventive science. At an early period we propose discussing the whole question exhaustively, and meantime we cordially invite the co-operation of our readers in approaching the subject. Mr. Corbet, the Medical Officer of Kidderminster, aptly remarked in the course of an able report, which is noticed elsewhere in our columns:—"Although it might be said that hospital isolation is not completely successful, yet, as far as yet known, isolation and disinfection were the only practical means for minimising the spread of the malady."

The Richmond Asylum.

The report of the Finance Committee on the estimates for the ensuing year have been presented to the board of the hospital. They show that to meet all charges the enormous sum of almost £100,000 will be required. This sum will, however, include not alone the Richmond Hospital but also the new auxiliary at Portrane, and a suitable allowance for an estimated increase of 150 patients during the year. The report shows that since 1894 the number of lunatic patients in the Dublin district has increased by 1,000. We are glad to note that the report bears testimony to the admirable manner in which the Resident Medical Superintendent, Dr. Conolly Norman, discharges his duties with regard to the management of the institution.

It is announced that His Majesty the King has consented to open the new University buildings at Cambridge early in March.

PERSONAL.

Mr. George Philip Francis, L.R.C.S.Edin., L.A.H.Dub., of Brecon, has been placed upon the commission of the peace for Breconshire.

The Lettsomian lectures of the Medical Society of London will be delivered by Mr. C. B. Lockwood on Monday evenings, February 1st, 15th, and 29th, at 9 p.m., upon "Aseptic Surgery in Theory and Practice."

Dr. J. Kingston Fowler will deliver a lecture at Brompton Hospital to-day, the subject being "The Treatment of Thoracic Aneurysm by Gelatin Injections."

On Thursday of the present week, Dr. F. J. Waldo, Coroner of the City of London, will deliver a lecture on the "Medico-Legal Relations of Insanity" at the Old Hall, Lincoln's Inn, London.

Dr. George Thin, of Harley Street, who died at Nice on December 27th, leaving estate of £29,975, bequeathed to the Royal Society of London and the Royal Medical and Chirurgical Society £100 each, and, on the death of Mrs. Thin, £100 each to the Middlesex Hospital and the Edinburgh Royal Infirmary.

Sir William MacEwen, M.D., F.R.S., will visit Cardiff and deliver an address to the local medical society on Friday afternoon next. Sir William is Regius Professor of Surgery in the University of Glasgow, and Surgeon in Ordinary to His Majesty the King in Scotland.

Mr. G. P. Rugg, M.D.Aberd., L.R.C.P.Lond., M.R.C.S.Eng., who has been the medical officer of the British Home and Hospital for Incurables at Streatham, London, S.W., for more than twenty-four years, recently received from the patients and nursing staff of the home a silver bowl.

Mr. C. F. Sutton, M.R.C.S.Eng., was recently presented by his patients and friends with a silver soup tureen, together with a silver tea and coffee service and tray, as a token of esteem on his retirement from practice after nearly forty years' residence at Holmes Chapel, Cheshire.

At the fifth annual dinner of the University College Colston Society, held in the large hall of the College at Bristol on January 21st, Mr. Henry Hobhouse presided and the principal speakers were Sir John Gorst and the President of Magdalen College, Oxford (Mr. T. H. Warren).

On January 14th, Alderman Graham, M.D., presided for the last time over the Public Health Committee when a special resolution was passed expressive of the great loss the City of Belfast and its council had sustained by the retirement of Dr. Graham. Dr. J. King Kerr has been since appointed chairman of the Committee.

Dr. D. C. Lloyd Owen, Consulting Surgeon to the Birmingham and Midland Eye Hospital, and Honorary Ophthalmic Surgeon to the General Hospital, Birmingham, has resigned his membership of the Spectacle Makers' Company in consequence of the action of the company in instituting an examination and issuing a Certificate in sight testing, an action of which Dr. Lloyd Owen disapproves.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

SCOTLAND.

SCOTTISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION. — From the annual report which was adopted at the meeting of this Association on January 22nd, it would seem that the efforts of the organisation to better the position of its members are being attended with some degree of success. The Association's attempts to improve the status and prospects of the Poor-law medical officers by legislation have so far not led to any definite results, the Bill introduced by Mr. Wason, M.P., not having reached a second reading. Allusion is made to the unsatisfactory state of matters shown by the return of medical officers discharged by parish councils; the return was quoted in this column some months ago. Regular advertising in the medical papers has induced many applicants for posts in the Highlands and islands to communicate with the secretary before proceeding with their candidature, and in nearly every case the result was that the application was not pursued. The lack of *ésprit de corps* displayed by some of the medical women who have taken these posts is deplored by the Association. A list of vacant parishes is given, with the reasons for which the previous holder of the office of medical officer had to resign or was dismissed. The Association numbers 350 members, less than one-half of the Poor-law doctors in Scotland, to whom an appeal, in which we strongly concur, is made to join the Association.

DISTURBANCES AT THE EDINBURGH UNIVERSITY RECTORIAL ADDRESS.—In the sequel to the disgraceful rowdyism which characterised the behaviour of the students at Sir Robert Finlay's address last week, two of the principal offenders were called before the Principal and Dean's committee, and were rusticated for two years. The sentence, though severe, is not unmerited, and will do more than much lecturing to show the undergraduates that there is a limit to folly, which, when overstepped, brings unpleasant consequences in its train. The Senatus are understood to have had the whole question of rowdyism under consideration at a subsequent meeting, and have resolved to take steps to put down this nuisance in the classes. It is stated that strong disapproval of the tone of the *Student*—the University magazine—was expressed at that meeting. A special meeting of the Representative Council was held on the 26th, at which a series of more or less self-condemnatory motions were carried with but little opposition. After apologising for the uproar, it is suggested that the students' concerts, at present preludes to the address, should be discontinued, that seating arrangements should be altered so as to admit of more effective "policing," that the professors should, the day before such a gathering, point out to the students the propriety of good behaviour, finally, one of the council, who acted as a ringleader, is called upon to resign his seat. For ourselves, we feel most strongly that it is not a question of merely suppressing the rowdyism which characterises public students' functions, but of doing away with the general insubordination and noise which disgrace many of the class-rooms from year's end to year's end. The first year's arts and medical students are the worst offenders, and if half a dozen of the ringleaders in each faculty were rusticated early in their career it might induce them to give up professions for which they are obviously unfitted, and leave the University in peace—neither would be losers by the change.

BELFAST.

BELFAST LOUGH FORESHORE NUISANCE.—A Local Government Board Inquiry into this subject was opened in Belfast last week, which greatly interests medical men. The city, as most people know, is situated just where the River Lagan flows into the Lough, and, as happens in all such places, there are great stretches of mud flats at the head of the Lough, covered by the tide at high water. Though thousands of acres have been reclaimed, many thousands more remain, and at every high tide are irrigated with the liquid sewage of the city, which, as the tide falls, emits anything but a savoury odour, especially if the sun happens to shine on it. Some years ago Professors Letts and Lorrain Smith, of Queen's College, investigated the cause of the smell, which is uncommonly "full flavoured." They found it was due to the decomposition of a green sea-weed, *Ulva latissima*, which flourishes in great abundance on the mudbanks, and which, containing a high proportion of sulphur in its composition, gives off great quantities of sulphuretted hydrogen as it decays. It might be thought that the inhabitants of the districts around the Lough, growing up in an atmosphere so flavoured, would become acclimatised, but it is only since 1890, or so, that it has become troublesome, the cause generally assigned being the introduction of the "main drainage system" at that time. Some idea of the quantity of weed may be inferred from the fact that during the summer and autumn months of 1900 and 1901 the District Council, which took the matter up on the co. Down side of the Lough, caused about 420 tons to be removed each day. Dr. Donnan, Medical Officer of Health for Holywood, stated in his evidence that the nuisance was both objectionable and injurious to health. The amount of sulphuretted hydrogen is so great that silver is quickly blackened. Dr. Chas. O'Neill and Dr. Thos. Greenfield corroborated Dr. Donnan's evidence. Dr. Letts (Professor of Chemistry in Queen's College, Belfast) gave a most interesting account of his experiments, carried out to ascertain the cause of the nuisance. It appears that the septic tank treatment of sewage, which is being tried in Belfast, results in the production of nitrates in abundance, and on these nitrates the seaweed flourishes. To render the sewage less nutritious to the weed it will therefore be necessary to submit it to further treatment, though what that will be has not been decided. As to the immediate lessening of the nuisance, Dr. Letts thinks that much might be done by the prompt removal of the weed as soon as it begins to accumulate in April, instead of waiting till it is at its greatest luxuriance from July to October. The inquiry has been adjourned till February 25th.

FORSTER GREEN HOSPITAL FOR CONSUMPTION, BELFAST.—At the annual meeting of this hospital, held last week, the medical report was read by Dr. Howard Sinclair. During the past year 186 in-patients were treated for periods varying from ten days to nine months. The average stay in the hospital, which is really a fresh-air sanatorium, is not given, but is apparently about two and a half months. The report dwells at length, as it has done every year for eighteen years, on the necessity for early treatment. It also mentions that the hospital grounds would accommodate ten times as many patients as there are, but owing to lack of funds they cannot be utilised.

BELFAST HOSPITAL FOR SICK CHILDREN.—At the annual meeting of this hospital the medical report stated that during the year 826 children had been treated in the wards, and 328 operations were performed. In the extern, 5,377 new cases were treated, and 304 operations were performed. In the excellent convalescent homes connected with the hospital 201 patients were treated.

SMALL-POX IN BELFAST.—Three new cases were reported last week, bringing the total number of cases since the beginning of the outbreak to about thirty.

German Dentist for the Korean Emperor.

WE understand the following notice has been published at Berlin:—"H.M. the Emperor of Korea desires to engage a German dentist for a period of two years. Terms: 300 yen monthly. Expenses allowed: Lodging, 30 yen; travelling expenses, 1,000 yen; for instruments, 4,000 yen; for establishing a laboratory, 50 yen. One yen equals two marks (or shillings). A consultation once a week at the Palace. Two months' leave granted annually, and private practice allowed. Knowledge of English or French essential."

Correspondence.

KOPLIK'S SPOTS IN MEASLES.

To the Editor of The Medical Press and Circular.

Sir,—The claims of individuals to priority in the description of morbid phenomena are always difficult to decide, for the reason that probably every clinical event in disease has, at some time or another, attracted the notice of at least one physician. No one would deny Darwin the credit that is his due because the question of organic evolution had been agitating men's minds for many a long year before the "Origin of Species" was published, nor because Dr. Alfred Russell Wallace had practically arrived at Darwin's conclusions at about the same time as Darwin himself. Jenner's work on the differentiations of typhoid fever from typhus remains classical, although for quite half a century before he published his results observers in many countries had been seeking to establish the same distinction. No piece of enduring work springs fully equipped from the brain of the thinker like Athene from the head of Zeus.

The occurrence of lesions of the mucous membrane of the mouth and palate in measles has been mentioned by writers for many years. Trousseau says that the mucous membranes of the respiratory tract and conjunctiva show the presence of the eruption on the first day, and that the disease is "inscribed" on the pharynx, tonsils, and velum palati before the appearance of the exanthem of the skin. Similar statements are made by other writers, Ringer being, perhaps, the first to mention definite white patches. He, however, confined them to the gums and inside of the lips. I have not the opportunity of referring to Professor Thomas' article in von Ziemssen's "Cyclopædia" of 1875, but I do not think that his description, however accurate, would invalidate the general argument of your leader, namely, that since the publication of Filatow's and Koplik's respective papers general attention was not directed to the almost universal occurrence and practical importance of these lesions.

Those of us who have had much to do with the health of communities of children have found Koplik's spots (or whatever their lecture designation may be) of the greatest help in the early diagnosis of measles, and I think your leader is likely to prove of great value in bringing the subject before the profession. Whilst thoroughly recognising the justice of Sir John Moore's intention, it seems to me that even his great experience had not led him to attach the weight to these lesions that they deserve, for instead of speaking authoritatively of them in his classical work, "Eruption and Continued Fevers," he quoted a not very full statement from Dr. Hilton Fagge's book. If Sir John Moore had been convinced of the value of these phenomena, would he not have described them himself and pointed out the assistance they render in diagnosis? It seems improbable that these spots are the homologues of the cutaneous eruption. They occur considerably earlier; they have a definite relation to certain structures, and they are explicable on other grounds. If one examines the buccal mucosa in measles one finds it generally injected and inflamed. Peeping through the reddened mucosa one finds white specks, namely, the papillæ, just as one sees the papillæ in the scarlet fever tongue showing through the pus. The mucosa over the papillæ being rubbed and fretted by the teeth or other contiguous structures tends to necrose, or one finds eventually where some of these white specks had been, little masses of dead epithelium with a margin of inflamed mucous membrane surrounding them.

As to the umlaut over the "o" in Koplik, perhaps you transferred it inadvertently from that over Knöspil's name, Knöspil having written on the same subject about the same time (*Prag. med. Woch.*, 1898, No. 41). I am, Sir, yours truly,

Hubert E. J. Biss.

Eastbourne, Jan. 30th, 1904.

ERYTHEMA SCARLATINIFORME.

To the Editor of The Medical Press and Circular.

Sir,—Dr. Robert Lee's letter in your issue of January 27th with reference to desquamative and non-desquamative erythema is of much interest to me personally because of its relation to a general law outlined by me in 1890 under the name of excretory irritation. I then ventured to claim that form of dermatitis as one of a series of inflammations of various excretory organs—*e.g.*, skin, kidney, intestine, bronchi. The common bond between these symptomatic excretory disturbances is the irritant, which may be chemical, bacterial, or of unknown tissue origin. Instances of each origin may be found in mercury, enteric fever and gout, which may either directly or indirectly inflame any of the excretory outlets of the body and give rise to diarrhœa, nephritis, bronchitis, dermatitis, and so on. In fact, the application of the general law of excretory irritation will be found to furnish a satisfactory explanation of the phenomena of many morbid conditions. So far as Dr. Lee's desquamative erythema is concerned, it supplies a rational *causa causans* for his original and acute observation of what is obviously a symptomatic condition.

I am, Sir, yours truly,

Grosvenor St., London, W. David Walsh.

ALOPECIA AND DENTAL CARIES.

To the Editor of The Medical Press and Circular.

Sir,—The letter of your correspondent, "M.R.C.S.," in your issue of the 27th, on dental caries and alopecia, seems to me to be based upon a somewhat out-of-date pathology. Nowadays it is pretty generally agreed that most forms of alopecia, no less than of dental caries, are due to bacterial invasion. The tissues of some individuals are more resistent to the adverse effects of such invasion than those of others. Early degeneration means simply lessened resistance to adverse conditions, due either to inherited or acquired weakness of individual constitution. The hair and the teeth of persons of good resistance will survive many years of partial damage. On the other hand, early degenerates, as we call them, lose both teeth and hair at a premature age. Why go out of the way to find less simple explanations? Again, the statement that the solid constituents of the teeth, once deposited, undergo no further change, appears to me to be a pure assumption. He would be a bold physiologist who would affirm a similar fact regarding bone. What facts are there to support such a theory in the case of dentine and enamel? I am, Sir, yours truly,

York, Jan. 30th, 1904. Medicus Senex.

Laboratory Notes.

ALLENBURYS MILK FOOD CHOCOLATE.

We have examined a sample of this Milk Chocolate, with the following results:—

Moisture, 0·76;
Albumenoids, 5·44;
Fat, 30·28;
Mineral matter, 1·54;
Cold water extract, 61·20.

This is an excellent example of a palatable sweetmeat, free from all objectionable additions and of real nutritive value. It contains a very high proportion of nourishment in a convenient, pleasant, and portable form and is very suitable for travellers, expeditions, &c. Some of the cheaper forms of chocolate are loaded with the husk or fibre of the cocoa bean, this is not the case with the article in question, which is of very fine quality, and may be given to children with the utmost confidence.

"TABLOID" ZINC VALERIANATE, Gr. ⅛ (0·13 gm.).—(Burroughs Wellcome & Co.)

The nauseous nature of zinc valerianate renders it unacceptable to the patient in its crude form. In the shape of the tabloid, however, it is possible to present this drug in such a condition that it can be taken by the most fastidious patients without difficulty. Zinc valerianate, made up into pills in the ordinary way,

is liable to become hard. The volatile constituent, moreover, usually permeates the coating, and renders the pill extremely distasteful. The tabloid zinc valerianate obviates these objections as far as possible, and should be useful to practitioners prescribing the drug. The salt employed is of exceptionally high quality, and the tabloid product disintegrates promptly on reaching the stomach.

"DARTRING LANOLINE" TOILET SOAP.

WE have tried this excellent soap and find that "Dartring Lanoline" Toilet Soap satisfies the requirements of a perfect soap. It claims to be an efficient detergent, while containing no free alkali, and not to deprive the skin of its natural protective oil. It is a true superfatted soap for an excess of genuine "Dartring Lanoline" above that necessary to secure complete saponification is present. We have no hesitation in saying that this soap is most excellent for toilet purposes.

New Instruments.

THE REPELLO CLINICAL THERMOMETER.

WE have received a most ingenious clinical thermometer from Mr. G. H. Zeal, of Turnmill Street, London, E.C. It is a "thirty-second" thermometer which can be set in an instant without shaking. The method whereby the mercury scale is restored to normal or to the desired degree below normal is simple. At the top end of the tube, opposite to the ordinary mercury registering bulb, is a second small round flattened bulb connected with a short column of mercury. After the thermometer has been taken from the patient's body and the temperature read the small top bulb is pressed between the fingers and the mercury expands. The result is that the mercury-registering index column at the lower end of the tube is immediately forced back into position by an air gap which is provided in the central tube between the two mercury bulbs. The old-fashioned way of shaking down the mercury into position has always proved tedious and a fruitful source of damage to these delicate instruments. If Mr. Zeal's invention stands the test of practical experience, as it promises to do, he will have conferred a distinguished service upon both medical men and nurses, not to mention patients.

Medical News.

Lectures on Medical Jurisprudence.

ON January 21st, the second of a course of lectures on medical jurisprudence was delievered by Dr. F. J. Waldo, coroner for the City of London, at the Old Hall, Lincoln's Inn. The lecturer dealt with "Live Birth in Relation to Civil and Criminal Law," a subject of great importance to lawyers. The consideration of live birth, he said, was naturally divided into two classes—namely, those which affected either civil cases of inheritance or criminal cases of infanticide. In both the evidence that established the fact of live birth was identical. The medical view of live birth differed from the legal. The medical man demanded proof of the establishment of circulation and of respiration even when the child had not been born into the world. In this way crying was one of the most satisfactory proofs of respiration and hence, to the medical mind, of live birth. The law, on the other hand, was content with the faintest sign of vitality, provided the child was fully born into the world, as establishing the fact of live birth. The tremor of a muscle or the quiver of an eyelid might be sufficient evidence of live birth from the legal point of view. The positive signs of live birth, as laid down by Casper, were next discussed, and the crucial point of viability or the capacity of a child to survive birth was treated at some length. The remaining lectures of the course will be delivered on subsequent Thursdays. They deal with death in its medico-legal relations, insanity, and poisons.

Scarlet Fever at Kidderminster.

MR. D. CORBET, medical officer for Kidderminster, reports that the death-rate last year was 16·76 per 1,000, or, subtracting the deaths of non-residents registered at the workhouse and infirmary, 14·57. There had been 590 notifications of scarlet fever in 1903, and one death, against 185 cases and one death in 1902. Dr. Corbet says the disease has been prevalent throughout the year. Many of the cases had been mild, and the carelessness often observed in these instances contributed very much to its spread. No part of the borough had been exempt from the disease, neither had Kidderminster been alone in this experience, for Stourport and Bewdley and the rural district of Kidderminster had sent an unusual number of cases into the borough hospital. Their experience indicated that they were passing through one of those recurrent periods when from conditions at present unknown there was a widespread susceptibility to the infection, or an extra degree of infectiveness in the germs of the disease. Although it might be said that hospital isolation is not completely successful, yet, as far as yet known, isolation and disinfection were the only practical means for minimising its spread. Further, it must be admitted that many lives have been saved, and certainly much sickness prevented, so that they had a diminution of deaths from the disease. All the elementary schools had been disinfected several times in the year and other precautions taken. The report of the sanitary inspector, Mr. Cowderay, has been issued with that of the medical officer, and gives much information on the work done in his department during 1903. It is stated that the rainfall of 1903 was 32·49 inches, compared with an average for the past ten years of 21·43.

North of England Obstetrical and Gynæcological Society.

AT the annual meeting of this Society, held at Owens College, Manchester, the following were elected office-bearers for the ensuing year :—

President: W. J. Sinclair, M.D. Vice-Presidents: S. Buckley, M.D., W. Walter, M.D., H. Briggs, F.R.C.S., T. B. Grimsdale, M.B., J. B. Hellier, M.D., A. C. F. Rabagliati, M.D., Sinclair White, M.D., Richard Favell, M.R.C.S. Members of Council: W. E. Fothergil, M.D., A. T. Helme, M.D., A. Hopkinson, M.B., S. Nesfield, M.D., D. Lloyd Roberts, M.D., J. P. Stallard, M.D., J. M. H. Martin, M.D., J. E. Gemmell, M.B., E. T. Davies, M.D., P. Edwards, L.R.C.P., R. Humphreys, M.B., J. McClelland, M.D., A. M. Patterson, M.D., J. N. Cregeen, L.R.C.P., J. Braithwaite, M.D., C. Richardson, M.R.C.S., C. J. Wright, M.R.C.S., A. E. L. Wear, M.D., Percival E. Barber, M.R.C.S., J. W. Martin, M.D., Robert Gordon, M.D. Hon. Treasurer: E. Octavius Croft, M.D. Hon. General Secretary: Arthur J. Wallace, M.D. Hon. Local Secretaries: John Scott, M.D. (Manchester), A. Stookes, M.B. (Liverpool), Walter Thompson, F.R.C.S. (Leeds), Sidney Barber, M.R.C.S. (Sheffield).

Death of Henry Edward Haycock, M.R.C.S.

WE regret to announce the death of Mr. Henry Edward Haycock, of Alfreton, Derbyshire. Deceased was educated at St. Bartholomew's and Durham, and took the M.R.C.S.Eng. in 1881, and the L.R.C.P.Ed. in 1882. He held the post of Medical Officer and Public Vaccinator for the Codnor Park and Bashford Union. His death took place at the early age of 45, and was due to an attack of pneumonia. A public funeral took place on January 28th, and was attended by a great and sympathetic concourse of residents in the neighbourhood.

Health in the School.

At a recent meeting of the Kidderminster Education Committee, Alderman Parry presiding, a report was read from Dr. Dudley, who had visited all the schools under the committee. A very serious defect in some of the schools was the very inadequate area of the playgrounds. The value of proper space for the purpose could not be over-estimated. Physical education ranked in importance with mental and moral education, and the two latter largely depended on the former. Whenever practicable, all physical education should be out of doors. During play-time the flushing of the school-rooms with fresh air should be carried out. Great importance was now being attached to the subject of physical deterioration; and the fundamental requisitions for securing health, on which every child should be educated, appeared to him to be (1) proper feeding in infancy, (2) pure air by day and night, (3) sufficient physical exercise, and (4) knowledge of the baneful influence of alcohol. His attention had been given to testing defective eyesight in the schools, to cases of deafness, and other ailments. The committee considered the report a valuable one, and it was decided that the recommendations should be duly considered. A number of matters on the agenda were dealt with seriatim.

The State Registration of Nurses.

The Bill promoted by the Society for the State Registration of Trained Nurses has been finally adopted, and will be introduced into Parliament in the forthcoming Session by Dr. R. Farquharson. The following members of Parliament have consented to back the Bill:—Sir Thomas Wrightson, Sir James Joicey, Sir John Batty Tuke, Mr. Haldane, K.C., Mr. Hugh Crawford Smith, Mr. R. C. Munro-Ferguson, Mr. H. J. Tennant, Mr. A. W. Black, Mr. C. E. H. A. Colston, Mr. H. Trelawney Eve, K.C., and Dr. Edward C. Thompson. At a meeting of the Central Hospital Council for London, held at St. Thomas's Hospital on Tuesday last, the following resolution was passed:—"That this council is opposed to any State registration of nurses, and that steps be taken on behalf of the council to oppose any Bill in Parliament having such registration for its object." Representatives of the following hospitals were present at the meeting:—St. Bartholomew's, St. Thomas's, Guy's, King's College, London, Middlesex, Royal Free, St. George's, St. Mary's, University College, and Westminster.

Death from "Laboratory" Plague.

The *Frankfurter Zeitung* publishes a telegram from St. Petersburg stating that in addition to Dr. Wichnekevitch, the director of the laboratory in Fort Alexander I. at Kronstadt, who recently died of plague contracted during experiments with living plague cultures, two assistants have now been seized with the disease.

The Drapers' School.

Dr. Hogan, medical officer of health, was granted an order lately at Tottenham Police Court to inspect the Drapers' School, where he said the sanitary inspector had been refused admission.

London Small-pox Statistics.

According to the official return of the Metropolitan Asylums Board, only nine cases of small-pox had been notified during the fortnight, as compared with fifteen in the previous fortnight. The total number of small-pox patients remaining under treatment in the hospitals was twenty-four, being a decrease of one on the preceding fortnight. The total number under treatment in the corresponding fortnight of 1902 was 882.

Medical Prizes of the Paris Academy of Sciences.

The list of prizes which will be awarded by the Paris Academy of Sciences during 1904 and subsequent years up to 1913 has now been published. The prizes vary from 200 francs to 100,000 francs. The following are those connected with medical subjects:—Prix Montyon: Three prizes of 2,500 francs for discoveries in therapeutics and improvements in medicine and surgery. Prix Barbier: 2,000 francs for a valuable discovery in medicine, surgery, pharmacy, or medical botany. Prix Bréant: 100,000 francs for a discovery relating to the cure, etiology, or prophylaxis of Asiatic cholera. Prix Mége: 10,000 francs for the continuation and completion of the work of M. Mége on the causes which have hindered or promoted the progress of medicine. Prix Leconte: 50,000 francs for new and important discoveries in mathematics, physics, chemistry, natural history, and medical sciences. Prix Serres: 7,500 francs for the best work on embryology, applied as much as possible to physiology and medicine. Prix Dusgate: 2,500 francs for the best work on the diagnostic signs of death and on the prevention of premature burial. Prix Parkin: 3,400 francs for researches on the curative effects of carbon in its various forms, and particularly in the gaseous form in the treatment of cholera, fevers, and other diseases. Prix Chaussier: 10,000 francs for the best work on legal medicine or practical medicine which has appeared for four years. Prix. Lacaze: 10,000 francs for works or memoirs which have advanced physiology.

PASS LISTS.

The Indian Medical Service.

The following were the successful candidates at the Indian Medical Service examination, held on January 19th, and four following days:—

	Marks.		Marks.
H. B. Drake ..	3,515	H. Watts	2,810
E. C. Hodgson ..	3,167	J. Anderson ..	2,800
W. S. McGillivray ..	3,046	W. S. Finlayson ..	2,799
W. Gillitt	2,991	H. E. Stranger-Leathes	2,792
W. F. Brayne ..	2,978	E. A. Roberts ..	2,789
M. S. Irani	2,899	G. G. Hirst	2,777
S. W. Jones ..	2,882	M. J. Quirke ..	2,753
W. Tarr	2,874	J. M. Holmes ..	2,684
C. H. Barbar ..	2,867	M. F. White ..	2,666
W. T. McCowen ..	2,839		
I. D. Jones	2,834		

Forty-two candidates (of whom 26 had University degrees) competed for 20 vacancies.

Society of Apothecaries of London.

The following candidates have passed during January in:—

Surgery.—R. S. Dollard, P. Elias, B. C. Ghosh, F. W. Higgs, W. G. Kinton, J. W. Watson.

Medicine.—W. V. Braddon, F. H. Hand, J. D. Keir, W. G. Kinton, E. H. Price, A. Rogers, A. Turner, S. Zweiback.

Forensic Medicine.—F. H. Hand, W. G. Kinton, A. Turner.

Midwifery.—H. Archer, C. H. J. Fagan, W. S. Lewis, P. B. Whitington.

The Diploma of the Society was granted to the following:—W. V. Braddon, R. S. Dollard, P. Elias, B. C. Ghosh, J. D. Keir, W. S. Lewis, and A. Turner.

Trinity College, Dublin.

At the examinations during Hilary Term, 1904, the following candidates passed:—

Anatomy and Institutes of Medicine.—William G. Harnett and William C. MacFetridge, equal; Joseph H. Elliott and Robert E. Dunn, equal.

Physics and Chemistry.—William F. Casey, William F. Samuels, Hercules J. Knox.

Botany and Zoology.—James C. C. Hogan, Rupert Magill, Robert L. Lee, Denis J. Stokes; Alexander K. Cosgrave and John H. Morton, equal; John A. L. Hahn, William F. Casey.

Final Examination: Section A.—George MacC. Millar, Howard English, Charles R. Morris, Benjamin Johnson, George E. Nesbitt, Montgomery D. Ferguson, William R. Galwey, William G. Harnett, Hercules J. Knox.

The South African Medical Congress, after a long interval, has just concluded its sixth meeting at Cape Town. The President was Dr. E. Sinclair Stevenson, a well-known Cape Town practitioner, and a former President of the Medical Council.

Notices to Correspondents, Short Letters, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

MISS J. W. POWER is referred to the paragraph which appears at the head of this column weekly; her letter was duly received at the London Office the day the journal is "put to press," and was referred back to the Dublin Office to be dealt with in the ordinary way, hence its non-appearance in present number.

LARANAGAS (Jamaica).—Your inquiry is an apt one. Alien immigration proceeds apace in the United Kingdom, where the only ground of exclusion is actual infection with some deadly complaint. Even in that case the exclusion simply resolves itself into detention under observation in an infectious hospital at the port of entry. In this way the United Kingdom has become the happy hunting-ground of a vast horde of aliens, who undersell the native workmen and furnish an undue proportion of criminals. Political economists tell us that in the long run the nation is the gainer by the influx of cheap alien labour. It is a question, however, whether the price paid for such an advantage may not be too great. In the case of Jamaica it should be possible to devise and enforce stringent laws for the exclusion of undesirable aliens. We shall be glad to learn if any such laws are in existence.

M. S. G. F.—Under the new London University scheme, professorial chairs will probably be founded at all the constituent medical colleges. At present only the lecturers in the medical schools of University and King's Colleges are able to call themselves "Professors."

SPES.—The question was so fully discussed in our columns a year ago, that we must decline to reopen it at present.

THE LATE DR. CONEYS.—A CORRECTION.

Owing in part to the necessarily hastily written note which we received from our Western correspondent regarding the sad death of Dr. Coneys, an omission occurred in our obituary which calls for correction. In eulogising the devotion and self sacrifice of Dr. Coneys, we omitted to make any mention of a man, a member of his own profession, who nobly stood by him in his last illness. Dr. Gorham, of Clifden, nursed Dr. Coneys devotedly through his illness. He sat with him for three nights before his death, and when the end came and Dr. Coneys' servants and friends fearing infection would not approach the sick room, Dr. Gorham, with the assistance of the nurses, was obliged to himself place Dr. Coneys in his coffin.

DR. EGGER (Budapest) is thanked for his communication.

DR. BARR (Liverpool).—Your paper on "Prognosis in Heart Disease" is marked for early insertion.

MR. H. WATSON.—It is a question for a transfer agent to decide rather than for an editorial opinion. We would advise you to consult Messrs. Wilson and Son, of Charles Street, St. James', or Mr. Needes, of the Adelphi, London.

Meetings of the Societies, Lectures, &c.

LONDON.

WEDNESDAY, FEBRUARY 3rd.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.)—8 p.m. Annual Meeting. Specimens:—Mrs. Scharlieb: Unruptured Tubal Gestation.—Dr. Blacker: Deciduoma Malignum.—Dr. Biggs: Primary Carcinoma of Fallopian Tube. The President (Dr. Malins, of Birmingham): Annual Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. J. Clarke: Clinique. (Surgical.) 5.15 p.m. Dr. T. H. Green: The Treatment of Pneumonia.

THURSDAY, FEBRUARY 4th.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Annual General Meeting. Dr. S. J. Sharkey: Presidential Address.

RONTGEN SOCIETY (20, Hanover Square, W.).—8 30 p.m. Discussion on Production of Photographic Reversal through the Action of various Radiations.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy Square, W.).—5 p.m. Dr. G. Johnston: Fibrosis of the Lungs, II. (with cases). (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6.15 p.m. Dr. M. Dockrell: Syphylis. (Chesterfield Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Mr. E. Clarke: Errors of Refraction, their Diagnosis and Treatment.

FRIDAY, FEBRUARY 5th.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.). 8.45 p.m. Mr. C. Ryall: The Surgical Treatment of Appendicitis.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Dr. E. Waggett: Clinique. (Ear.)

DUBLIN.

ROYAL ACADEMY OF MEDICINE (Obstetric Section).—Adjourned discussion on Dr. Purefoy's report of the Rotunda Hospital. Papers: Drs, Jellett and Earl:—Sarcoma of the Vagina with notes on a case; Dr. Tweedy:—Some interesting cases occurring in the practice of the Rotunda Hospital for the seven weeks ending 31st December, 1903; Dr. Alfred Smith:—Tuberculous Ulceration of the Cervix with notes of a case. Specimens: Dr. Alfred Smith:—Uterus removed by Panhysterectomy containing a large sessile polypus.

Vacancies.

York Dispensary.—Resident Medical Officer, Salary £120 a year, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York

The Hampstead General Hospital.—Resident Medical Officer, Salary £120 per annum, with rooms, coal, and gas. Applications to George Watts, Secretary.

North Riding Infirmary, Middlesbrough, Yorkshire.—Assistant House Surgeon, Salary £75 per annum, with bed, board, and washing. Applications to Angus Macpherson, Secretary.

Ancoats Hospital, Manchester.—Resident House Physician, Salary £80 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

Liverpool Dispensaries.—Assistant Surgeon, Salary £100 per annum, with board and apartments. Applications to Sam. B. Leicester.

Inverness District Board of Lunacy.—Medical Superintendent for the Inverness District Asylum. Salary £500 per annum, with free house, fire, light, vegetables, and keep of one horse. Applications to Messrs Anderson and Shaw, Solicitors, Inverness.

Barnwood House Hospital for Mental Diseases, Gloucester.—Junior Assistant Medical Officer, Salary £150 a year, with board, &c. Applications to the Medical Superintendent.

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer, Salary £150 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

London County Asylum, Horton, Epsom.—Junior Assistant Medical Officer, Salary £150 per annum, with board, furnished apartments and washing. Immediate Application to R. W. Partridge, Clerk of the Asylums Committee. (See Advt.)

Richmond District Asylum, Dublin.—Two Clinical Assistants, Salary £60 per annum, with furnished apartments and full rations. Applications to Conolly Norman, Medical Superintendent. (See Advt.)

Appointments.

BULLMORE, CHARLES CECIL, L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer to the Workhouse and Falmouth District by the Falmouth Board of Guardians.

GARTRELL, JOHN HERBERT, L.D.S.Eng., Honorary Dental Surgeon to the West Cornwall Infirmary and Dispensary, Penzance.

HARMER, W. D., M.C.Camb., F.R.C.S.Eng., Surgeon to the Metropolitan Hospital, Kingsland Road, N.E.

HAY, JOHN, M.D., Ch.B.Vict., M.R.C.S., L.D.S.Eng., M.R.C.P.Lond., Physician to the Liverpool Stanley Hospital.

HEILBORN, W. E., M.B., B.C. Cantab., Honorary Assistant Medical Officer to the Bradford Children's Hospital.

HERN, GEORGE, L.R.C.S.Lond., M.R.C.S., L.D.S.Eng., Dental Surgeon to the Royal Dental Hospital of London.

OUSTON, THOMAS GEORGE, F.R.C.S.Eng., L.R.C.P.Lond., a Medical Referee under the Workmen's Compensation Act, 1897 and 1900, and to act for the Morpeth and Blyth, North Shields, Newcastle, Gateshead, Hexham, and Bellingham Districts in County Court Circuit No. 1.

PORTER, W. GEORGE, M.D.Brux., M.R.C.S., F.R.C.P.Lond., Clinical Assistant to the Chelsea Hospital for Women.

PRATT, J. DALLAS, M.D.Dub., F.R.C.S.I., Certifying Surgeon under the Factory Act for the Dublin District of the county of Dublin.

RIDDELL, J. SCOTT, C.M.Aberd., Additional Examiner in Clinical Surgery, Edinburgh University.

ROUS, J. B., L.R.C.P., M.R.C.S., House Surgeon to the Hastings, St. Leonards, and East Sussex Hospital.

SCRASE, JAMES, M.R.C.S., L.R.C.P., Honorary Medical Officer to the Newton Abbot (Devon) Hospital.

WALKER, ALFRED, M.A., M.D., B.C.Cantab., Honorary Medical Officer to the Budleigh Salterton (Devon) Cottage Hospital.

WARING, H. J., M.S.Lond.,, F.R.C.S.Eng., Consulting Surgeon to the Metropolitan Hospital, Kingsland Road, N.E.

Births.

BASSETT-SMITH.—On January 28th, at the R. N. Hospital, Haslar, Gosport, the wife of Fleet Surgeon P. W. Bassett-Smith, R.N., of a daughter.

BREND.—On January 28th, at 43, Campden Hill Court, Kensington, W., the wife of William A. Brend, M.B., of a son.

Deaths.

CHAPMAN.—On January 28th, 1904, at his residence, The Pines, Hampton Wick, E. J. Chapman, LL.D., P.H.D.

DOVE.—On January 27th, 1904, at 'Ardestie, Northwood, Middlesex, John Reuben Bathurst Dove, M.B., B.S.Lond., late of Pinner, in his 67th year.

WRIGHT.—On January 27th, at 153, Upper Kennington Lane, S.E., John Sidney Albert Wright, L.R.C.P., L.M.Edin., L.S.A., aged 64 years.

VOL. CXXVIII. WEDNESDAY, FEBRUARY 10, 1904. No. 6.

A Clinical Lecture
ON
DERMOIDS: OVARIAN AND PELVIC,

DELIVERED AT THE SAMARITAN FREE HOSPITAL ON THURSDAY, NOVEMBER 5TH, 1903.

By ALBAN DORAN, F.R.C.S.,
Surgeon to the Hospital.

FOR practical purposes the characters of an ovarian dermoid are well known. We are all aware that they are cystic tumours containing greasy fluid, felted hair, bone, teeth, skin and more complicated structures. On the theories, or rather doctrines, which profess to explain their origin we need not dwell, I only mention them because patients and their friends, hearing about the bones and teeth, not rarely ask questions, and expect an explanation. "Parthenogenesis" is no explanation, but simply reminds us that dermoid cysts may be found in little girls; the term should be limited to a phenomenon seen in certain insects where an unimpregnated female may produce fertile ova, the produce of which, however, are, I understand, sterile unless impregnated. "Fœtal inclusion" is open to much objection, as is "the inherent formative power of the ovary."

We cannot really explain why dermoids grow, but we can often manage to treat them very satisfactorily. Knowing what they are like, we must bear in mind some of their relations and associations.

First, granting that we have to do with a dermoid diagnosed by palpation, or even actually exposed at an operation, we must remember not only that the great majority of abdominal dermoid tumours are ovarian, but also that a dermoid tumour found in the abdomen quite separate from the uterine appendages may, nevertheless, be of ovarian origin. Hence it is of great importance when such a tumour is discovered to draw up the uterus and examine its appendages with care. The chances are that in such a case a stump will be found replacing one ovary and tube, in other words, the dermoid was of ovarian origin, but has twisted itself off its pedicle. It usually adheres to the great omentum, that interesting serous fold which the modern school of surgery has learnt to utilise so freely. It will establish collateral circulation and relieve ascites when stitched to the parietal peritoneum in certain cases of cirrhosis, it will guard the general peritoneal cavity if sewn to the abdominal wound under a diseased gall-bladder which requires drainage, but is too contracted to be fastened safely to the parietes, and it will greatly fortify the repair of plastic wounds in surgical operations on the stomach and intestines. The fostering qualities of omentum adherent to cysts detached from their original blood supply suggested the utilisation of that process of peritoneum for surgical purposes.

In a case of this kind, I repeat, the uterus should be carefully examined, not only to see if the appendages be wanting on one side, but when this condition is detected to ascertain the state of the opposite ovary, for ovarian dermoid disease is often bilateral.

Yet we hear that an abdominal or pelvic dermoid may be non-ovarian. This is quite true, for it has been found in a male, and not as a homologue of an ovarian tumour—in plainer words, not as a tumour of the testicle. We need not dwell on dermoid elements in the testicle, as they are clinically very different from ovarian dermoids. The possibility of a cystic abdominal tumour in a male being dermoid should be borne in mind in these days when surgeons are always ready to extirpate any removable tumour. In Ord and Sewell's case a robust young country gentleman suffered from an abdominal swelling. On tapping, two pints of thick, greasy fluid containing hairs came away. The patient died in a few days, and a retro-peritoneal dermoid was found firmly united to the bladder and rectum. Wilks and Curling report another instance where a pelvic dermoid existed in a man, æt. 21. It pressed into the rectum and was tapped, two pints of oily fluid coming away. Eight years later a calculus was removed by lithotomy; it had a nucleus of hair. Thus a dermoid abdominal or pelvic tumour may develop in a male; other cases besides those quoted have been recorded. In these days a doubtful cyst is explored, not tapped; the escape of dermoid fluid into the peritoneal cavity is obviously dangerous.

The non-ovarian retro-peritoneal tumour is, however, much more frequent, or, rather, less rare, in women than in men. It burrows very deeply in the pelvis and may lie anterior to the uterus, or between it and the rectum, or completely behind the rectum, in which case it causes the perineum to bulge freely, and has been removed through an incision between the rectum and coccyx. This kind of dermoid is sometimes first recognised by the discharge of hair and grease from the rectum or in the urine.

Retro-peritoneal non-ovarian dermoid is, however, exceedingly rare, many recorded cases being

doubtful, or, more correctly speaking, instances of ovarian dermoids transplanted to the omentum. Returning to genuine ovarian dermoids, the most important question in respect to their characters is, Are they innocent or malignant? It is now known that true pathological malignant degeneration of this kind of tumour is quite exceptional, and occurs late in the development of the growth. But the dermoid tissue not rarely implants itself on the peritoneum outside the cyst wall; this prejudicial change is constant in a form of dermoid mainly solid, named *teratoma*.

Dermoid cyst of the ovary proper is a very common tumour. I have operated in this hospital on five cases during the past summer. The percentage of dermoids in relation to other ovarian tumours is much higher than was once supposed, for mixed adenomatous and dermoid multilocular cysts are quite frequent. Only last month I removed a large cystic tumour, emptying during the operation several pints of typical ovarian fluid, free from dermoid elements, from a cyst larger than its fellows; afterwards grease and hair were found in some of the lesser cavities. Such an experience is common in ovariotomy. Ovarian dermoids proper are rarely multilocular, and nearly always pedunculated, which is fortunate, as enucleation would involve risk of escape of septic grease. They are often bilateral, so that it is always necessary to make sure of the condition of the opposite ovary when an ovarian dermoid is removed.

This frequency of bilateral dermoid disease is specially important to bear in mind in cases under puberty. Ovarian cysts in children are nearly always dermoid, so when a cyst is diagnosed in a child the possibility that both ovaries may require removal must not be overlooked, and the consequences of double ovariotomy must be explained to the patient's friends.

Ovarian dermoids are met with in women of all ages; children, young girls, parous subjects, elderly virgins, and old women who have borne children. In age they appear sometimes, as in a case which I shall relate, to lie latent, but I have removed large dermoids in an active state of development from old patients.

There are four clinical features of special interest in relation to the common ovarian dermoid. (1) If diagnosed early, ovariotomy proves easy and highly successful. (2) Twisting of the pedicle and worse complications are very frequent. (3) Association of an ovarian cyst with pregnancy, labour, and the puerperium is specially serious when the tumour is dermoid. (4) Neglected dermoids cause dangerous and intractable complications.

Early diagnosis of an ovarian dermoid is one of the greatest services which a doctor can render to a patient, and if the tumour be successfully removed cure is complete, for a dermoid is not pathologically malignant, so there will be no recurrence in the pedicle. The tumour has not, in such a case, contracted adhesions, its pedicle is rarely broad and usually narrow, and above all, none of the contents have escaped into the peritoneal cavity, nor has bone or hair worked its way into the bladder or rectum. Even twisted pedicle, so frequent in dermoids, at first facilitates the operation, the ovarian vessels being usually plugged. If operation be delayed serious effects may arise from this complication.

An ovarian dermoid forms a tumour of small and moderate size, usually occupying the middle of the abdomen up to or above the umbilicus. A very large dermoid is often compound, the main loculi being freed from dermoid elements, but this is not a matter of much clinical import. There will be resonance in the epigastrium and flanks. Free fluid in the peritoneal cavity is very unusual, just as in uterine fibroid disease. In cases of glandular ovarian cyst this condition is not rare; in fibroma of the ovary (which has been taken for a dermoid when very soft) it is frequent, and in free papilloma or malignant disease of the ovary constant.

A dermoid ovarian tumour may fluctuate quite distinctly, but as a rule fluctuation is obscure, and there is a doughy feeling on palpation. Above all, irregular degrees of consistence in different parts of the tumour are very characteristic in most dermoids. It may feel tense high up, hard on one side, almost spongy on the other, doughy below, and so forth. When a mass of bone can be felt, diagnosis is practically certain. A true included monstrous fœtus never lies in a movable cyst and well up in the abdomen; a retained extra-uterine fœtus in a sac is associated with conditions in the pelvis and disturbances of the catamenia which are not to be detected in a case of uncomplicated dermoid, whilst a normal uterine fœtus should never be taken for bone in a dermoid cyst. As a rule, I find that bony plates in ovarian dermoids are not to be detected by palpation, even though plenty may be found in the tumour after or during its removal.

An ovarian dermoid is quite movable at first, and on pelvic exploration the uterus is nearly always far back, behind the lowest part of the tumour, which comes down to the level of the pelvic brim, if not lower. These relations are, however, by no means constant. Occasionally, as in a case where I operated here last month, the entire uterus lies forward, pushed upwards by the dermoid which comes down into Douglas's pouch.

When very small, a dermoid not rarely lies altogether in the pelvis, and occasionally remains there even after attaining a considerable size. Diagnosis is not always easy, but occasionally the doughy feeling is very evident on bimanual palpation. A pelvic dermoid is a distinct source of danger in young married women, as it will obstruct labour, and may rupture, especially should obstetrical operations be necessary.

But complications often set in early. Ovarian dermoids are particularly liable to torsion of the pedicle, intra-cystic hæmorrhage (very rarely serious), adhesions due to irritation and inflammation of neighbouring peritoneum, septic infection of the contents and escape of the contents from the cyst cavity, either through rupture of the cyst wall or by processes which allow hair or bone to grow through the wall.

Even very early in its history a dermoid is often tender to touch, a fact which aids in diagnosis. A history of a very sharp attack of pain is not rare, while very often the patient complains that she has suffered from dull pain for several days.

The sharp pain means acute torsion of the pedicle; the dull pain, if observed by a medical attendant to be free from rise of temperature, signifies slow torsion. The latter complication, much the more frequent, is, however, often associated with local

peritonitis, and in that case there will be more or less feverishness. I once observed both forms of torsion in a patient under my care here with double ovarian dermoid disease. She had been subject to abdominal pains difficult to localise. After passing a motion she felt the most intense pain in the abdomen, and I found her moving about her bed in great agony, with free, cold perspiration. On operating, the right ovary was found converted into a big tumour, extremely livid and full of grease. Its pedicle was tightly twisted, with turgid veins and a large empty artery. The opposite ovary formed a yet larger dermoid tumour with its pedicle atrophied through chronic torsion. The patient on recovering from the anæsthetic, declared that she felt extreme relief as all pain was gone; this is not the rule immediately after an ovariotomy, but the pain caused by the ligatures on the pedicle was relatively so slight as compared with the sufferings due to torsion that the patient hardly perceived it.

Septic changes in the contents of a dermoid cyst are frequent, and in non-puerperal cases are usually due to the bacillus coli entering at a point on the wall where there are adhesions. They add to the risk of complications after ovariotomy.

Pregnancy involves yet greater risks, and in the puerperium worse germs than the bacillus coli may infect the cyst. We see a great deal of the results of pregnancy complicating ovarian tumours in this hospital, and dermoids specially cause trouble. The complications above described, particularly torsion, are very apt to occur during pregnancy.

There can be no doubt that the tumour is more prejudiced than the pregnancy, for torsion of the pedicle, even when acute, does not necessarily cause abortion; delivery may be perfectly normal, provided that the tumour be above the pelvis, whilst the puerperium may proceed normally as far as the uterus and general system are concerned, although the cyst is at the same time becoming infected.

The treatment of pelvic dermoids during delivery is a grave matter, which we cannot fully discuss at present. Ovariotomy through an abdominal incision is probably the safest course, provided there be both a competent operator and satisfactory nursing and appliances at hand. Opening the cyst through a vaginal incision sounds simple, but after clearing away the fatty contents, often mixed with much hair, the cyst wall may be torn off in part as it is drawn down, so that the remainder of the tumour with the pedicle unligatured will slip back into the peritoneum. Dangerous hæmorrhage and peritoneal infection will ensue. It has been suggested that the experienced obstetrician, who has never done an ovariotomy, had better, in such a case, make an abdominal incision and draw up the tumour above the pelvic brim, closing the wound, delivering the woman, and then preparing her for operation after the puerperium.

These considerations, however, are mainly obstetrical and too much open to grave debate to be suitable for this lecture. As a rule the dermoid does not prejudice gestation, but is liable to complications during pregnancy, and is much exposed to infection in the puerperium. Experience teaches us that the removal of the dermoid during pregnancy is not dangerous, whilst abortion does not necessarily follow the operation, and should it ensue it hardly interferes with recovery. But experience likewise reminds us that the risk of ovariotomy is greatly increased when the cyst and its greasy contents have undergone puerperal infection. On that account we should strongly advise a pregnant patient, who has an ovarian cyst, to have the tumour removed during pregnancy. Should she refuse, she should be kept in bed after the puerperium, and not allowed to rise before the operation is performed.

The spilling of grease, often mixed with hair, into the peritoneal cavity may necessitate flushing with saline solution, or free "toilet" with pads, but such manipulations increase the chances of abortion. Hence a small dermoid is best extracted entire through a free incision in the middle line, whilst if large, great pains must be taken to prevent grease escaping into the abdomen when the cyst is opened. A trocar and cannula are quite useless unless the fluid in the cyst is thin and abundant.

In my own practice I have detected chronic torsion of the pedicle with dense adhesions in six cases of ovariotomy on dermoids diagnosed (as tumours at least) before a recent pregnancy. The patients recovered, though the operation was always difficult, save in one very bad and neglected case of puerperal infection with fœtid fluid in the cyst and close adhesions to large and small intestines. In conclusion, I will relate a case where I operated in this hospital last spring, on a patient who had been delivered of twins two years previously. Labour was on that occasion impeded by the tumour, which occupied part of the pelvic cavity, rising into the left iliac fossa. Once more the patient became pregnant and labour was induced at the sixth month, nine months before I performed ovariotomy. I found a small heavy dermoid of the left ovary full of fat and felted hair, strongly adherent to the uterus and rectum; the right ovary was dermoid and required removal. Convalescence was rapid, but the case is instructive as showing how a dermoid cyst may imperil labour, and may itself be endangered by the processes of gestation.

Neglected dermoids were once very often seen in hospitals. When I was house-surgeon at St. Bartholomew's, in 1871, I saw two women, one almost a child, with pus and hair discharging from the bladder and rectum. Occasionally such cases are witnessed at the present day in patients who dread operative measures. Excision of part of the bladder or of intestine may be necessary, whilst in some cases the dermoid elements cannot be thoroughly extirpated. When the rectum is damaged by the separation of dense adhesions during the removal of an old dermoid, it is often advisable to drain by the vagina, and to sew the broad ligament to the peritoneum of the posterior part of the pelvis and upper portion of the rectum above the seat of injury. In this way the peritoneal cavity is cut off from a focus of deadly infection; abdominal drainage is untrustworthy in such a case.

Under circumstances not clearly understood, small pelvic dermoids may lie latent for years and fail to contract adhesions. I removed a tumour of this class last summer from an old lady, æt. 63, in a nursing home, and the results were satisfactory. Most probably growth is arrested in these cases by plugging of the vessels in the long, narrow pedicle of the heavy little tumour.

SOME CASES OF LYMPHANGIOMA.

By ALBERT CARLESS, M.S.LOND., F.R.C.S.,
Professor of Surgery in King's College, London; and Surgeon to King's College Hospital, &c.

IT has fallen to my lot to treat a number of these growths during the last few years, and inasmuch as their characters and peculiarities are none too clearly described in text-books, and my cases have ranged over most of the different types assumed by them, it has seemed worth while picking out some of the more characteristic so as to give an idea of the whole subject.

It is a little difficult to draw an exact line of demarcation around growths which should merit the title: between them and the lymphangiectases a somewhat large group exists, of which it is almost impossible to say to which class one should assign the individual members. Theoretically, one looks on a lymphangioma as a tumour built up of *newly-formed* lymphatic vessels, whether or not they retain their tubular characters, whilst the lymphangiectases are conditions due to the distension of *pre-existing* lymphatics, and the latter are usually associated with interstitial overgrowth of the tissues involved, constituting in the extremities conditions akin to elephantiasis. The difficulty in particular arises with the unilocular or multilocular cysts which form the majority of cases known as cystic hygroma; whilst the term lymphangioma is usually applied to these, it is, to my mind, quite an open question whether it is strictly merited.

I propose to lay before you the characters of five cases. Of these one was purely cutaneous; two involved skin and subcutaneous tissue; three were typically cystic; and the last was a solid growth, but covered by, and associated with, a marked cutaneous development.

Case 1.—The patient was a child, æt. under 12 months, of poor physique and badly nourished. It was affected by a patch of lymphangiomatous tissue upon the temple, the size of a shilling or a little more. It presented the typical appearance of what may well be termed a *lymphatic nævus*. The patch was of brownish-yellow colour; the surface was slightly irregular and papillated, and on examination with a lens one could see that each of the enlarged papules of the skin was the seat of a dilated lymphatic covered with epithelium. There were a few enlarged blood-vessels in the neighbourhood. As the condition was not increasing in size, and as the child's nutrition was peculiarly defective, I advised that it should be carefully watched and not dealt with at the time; any increase would determine active treatment, in the shape either of destruction by the actual cautery or excision.

In the third and fifth of the cases here recorded, a similar condition was present in association with deeper lymphangiomatous manifestations, but was spread over a much more extensive surface. Not infrequently patients scratch and irritate the affected areas, giving rise to a flow of lymph from the surface, and perhaps followed by attacks of inflammation, which may lead either to extension or to cure.

This lesion is sometimes associated with a condition in which the lymphatics are distended to such a degree as to constitute vesicles as large as half a pea, but the latter may also occur without the former. These *lymphatic varices* are by no means uncommon, and are best treated by simple extirpation if they be few in number, or by opening them and cauterising the exposed surface. A very good illustration of this "lymphangioma circumscriptum" appeared in the *British Medical Journal* on June 3rd, 1893.

Lymphangiomata of the subcutaneous tissues similarly present themselves under two chief manifestations—*viz.*, the tubular, and the cystic or cavernous. In the former, as in the hæmangiomata, the newly-formed vessels remain as capillaries, and constitute soft, pulpy or spongy swellings, which can sometimes be reduced in size on pressure. In the cavernous type, cysts of greater or smaller size are found, associated or not with the spongy tissue just mentioned, and filled with lymph, to which a greater or less quantity of recent or old blood is not infrequently added. On the whole, one is inclined to think that the purely cavernous without admixture of spongy tissue is more frequently seen. As an illustration of this, the following case may be noted:—

Case 2.—D. M. S., æt. 5, admitted to King's College Hospital on September 9th last for a cystic swelling situated in the lower part of the right cheek and upper part of the neck. It had only been noticed three months previously, but during the month preceding her admission it had increased in size very considerably. It extended upwards as high as the external auditory meatus, downwards to the level of the thyroid cartilage, backwards to the anterior border of the sterno-mastoid, and forwards nearly as far as the middle line. The swelling was tense and elastic, apparently loculated, and the skin over it was normal and moved freely; the growth appeared to be more or less attached to deeper structures. The limits of the swelling were quite sharply defined, and it was obviously of a cystic nature. It was operated upon on September 11th, and on incision proved to be a thin-walled multiloculated cyst, containing serum mixed with blood, which from its colour had been extravasated into it some little time. The various loculi penetrated deeply among the structures of the neck, and were in close proximity to the vessels; the lingual and facial arteries projected into the cavity, and were only separated from it by the endothelial lining. One loculus ran up under cover of the mandible into the pterygoid region. It was impossible to dissect out in its entirety the whole of the lining wall, and hence those portions which could not be thus dissected away were well scraped with a sharp spoon. The wound was closed with a continuous suture and healed by first intention.

I look on this growth as a pure cystic lymphangioma, though why it appeared in this situation, and why it developed so suddenly and rapidly, it is impossible to say. Its definite limitation rendered it very suitable for treatment by operative measures. Not a few growths ordinarily termed cystic hygroma are of this type; they are perhaps more often composed of a congeries of smaller cysts than of a single one, but they are frequently quite amenable to operative treatment. It is by no means unusual to see a hæmangiomatous element also present, and this association may explain why the fluid contained in them is stained or mixed with blood. In one instance which I saw years back under the care of Lord Lister, it was possible to reduce the size of the mass by pressure to a considerable extent, and as soon as the compressing force was removed the tumour swelled up to its former dimensions.

Quite distinct in their features from this, although still cavernous lymphangiomata, are the next two cases.

Case 3.—H. G., a boy, æt. 6, came under my care at St. John's Hospital, Twickenham, about two years ago. He was the subject of a large cystic swelling on the left side of the posterior thoracic and abdominal walls. This had existed from birth, but had increased in size rapidly during the previous few months. The mass extended from the mammary line in front nearly to the middle line behind; from above downwards it was about four inches in diameter, and projected outwards to such an extent that it resembled in size a large cocoanut. Several cysts could be detected, but the main loculus was of considerable dimensions. The skin covering the mass was adherent to it, and in part the seat of a cutaneous lymphangioma resembling that described in Case 1. The growth appeared to be more or less fixed to the thoracic parietes. I dealt with it in two operations. In the first the incision was a straight one placed across the centre of the mass, and extending from an inch and a half external to the left nipple obliquely downwards and backwards nearly to the middle line behind just above, then to

the top of the sacrum. The main cyst was thereby opened and found to contain serous fluid. Many other cysts were present, but in addition to this was a considerable quantity of a soft spongy tissue which oozed lymph when cut into, and was much of the same character as the soft spongy hæmangiomatous tissue found in ordinary nævi. This, together with the lining wall of the main cyst and the greater portion of the affected skin, was dissected away; but it was found that the soft nævoid tissue extended into and had infiltrated the superficial muscles covering the thorax and abdomen, and it was necessary to encroach on these to a considerable extent in order to get clear of the growth. There was a good deal of bleeding in this procedure, and therefore it was thought wise not to attempt the total extirpation of the outlying portions of the mass towards the middle line. The patient recovered perfectly well, and some time later a second operation was undertaken in order to remove the remains of the tumour, which had once again started growing. This time one made a curved incision extending from the upper end of the scar to nearly the lower, and reaching back as far as the middle line. This large flap was dissected up, and all the remaining portions of the growth were removed. The wound healed by first intention. I saw the patient a few weeks back—*i.e.*, eighteen months after the second operation, and found that the condition was perfectly satisfactory; there was no sign of any recurrence, and the skin only in one spot showed evidence of the preceding lymphangiomatous condition which had involved it.

Case 4 was a less satisfactory one of a similar type, in which, however, a fatal issue ensued in spite of extensive interference.

M. E., æt. 3 days, was admitted to King's College Hospital under Mr. Rose on March 3rd, 1902, with a large cystic swelling beneath the left side of the jaw, extending from the symphysis menti to the mastoid process. The skin was not adherent over the mass, and several distinct cysts could be made out. The growth increased rapidly in size, several of the cysts appearing to merge into one another under observation, and the mass soon began to project further backwards behind the sterno-mastoid. On March 10th Mr. Rose operated, making an incision more or less parallel with the ramus of the jaw over the more prominent cysts. The skin was separated from them, and the cysts opened. They contained yellow serous fluid and a substance of jelly-like structure, probably due to coagulation of the lymph *in situ*. The greater part of the mass was removed and its pedicle ligatured. The wound was closed and the child did well, but the notes state that on March 20th, before the child was discharged, the tumour under the chin was again commencing to enlarge. The fluid contained in the cysts is reported by Dr. Grünbaum to contain 0·4 per cent. of albumen. The wall of the cysts was composed of connective tissue, in parts undergoing myxomatous degeneration; the cyst cavity was not lined by epithelium. The solid material in the cysts was said to be organising fibrin.

The child was admitted a second time under my care a few months later. The growth had then attained considerable dimensions, extending under the chin as a projecting rounded mass, and also occupying both triangles of the neck. The child's nutrition had by this time begun to suffer, and although operation was essential, one was a little afraid as to what the result would be. A large incision was made, extending the whole length of the lateral aspect of the neck, and it was early seen that the sterno-mastoid was extensively invaded by the growth, and that removal of its whole thickness in a portion of its extent was required—in fact, there were very few muscle-fibres left towards the centre. The growth had also attacked the parotid gland, and its removal from this region necessitated the division of a portion of the facial nerve. In spite of the very extensive dissection, it was impossible to remove the whole mass, especially under the chin. When the operation was finished the whole of the deeper structures of the neck were laid bare, and one had to place the skin-flap down on the internal jugular vein with no other structure intervening. In spite of all things, the wound healed satisfactorily, and the child was sent out of hospital; but, unfortunately, the side of the face remained partially paralysed.

The ultimate result was that the tumour grew once again, burst through the skin, and became infected. The child was admitted to hospital for a third time on January 10th, 1903, and died of septic absorption.

The most important feature in each of these two cases is the tendency obviously existent in them to infiltrate surrounding structures. The sterno-mastoid in one case, and the superficial abdominal muscles in the other, had been invaded, and their tissues infiltrated and destroyed; the parotid gland in Case 4 had also been attacked. In the former case the parts involved were of less importance, and therefore could be freely dissected away; but when the deeper tissues of the neck are affected, serious results may follow, and life itself may be destroyed. This tendency to invade and infiltrate has been noticed by other observers, and must ever be kept in mind in advising as to treatment. The tissue is plainly of a lowly organisation, and it is quite an open question whether there is not some added sarcomatous element present. A similar instability of the hæmangiomata has also been noticed.

Mr. Betham Robinson related a case somewhat similar in which the parotid region was invaded by a growth of this nature, though there it was simply cystic and not of the spongy type. An operation was undertaken, but only a portion could be removed. The growth recurred, and the child subsequently died of asthenia ("Path. Soc. Trans.," 1896). Mr. Spencer has also reported to the Medical Society a case of diffuse lymphangioma of the lower extremity, and has referred to some others of a similar type; but they do not seem quite to fall into line with cases such as I have referred to, and are more like diffuse lymphangiectases ("Med. Soc. Trans.," 1892, p. 133). Zuccaro (*Puglia Medica*, 1894, Nos. 8 and 9) also relates a case of diffus ecystic disease of this type in the upper arm and thorax of a child seventeen days old, where the connective tissue was riddled with cysts, and gives a careful account of the histology. Complete removal was impossible, and death occurred as the result of septic processes starting in the wound, which could not be completely closed. Vautrin (*Revue de Chirurgie*, 1898, p. 1,128) relates a case of mesenteric lymphangioma which he discovered post-mortem. The growth had invaded the muscular tunics of the stomach, and was surrounded by agglutinated coils of intestine. He emphasises the gravity of this invasion, and looks on it as analogous to that of a malignant tumour.

Operations for partial removal must therefore always be avoided, if possible, but there are not a few cases on record in which a good result was subsequently obtained. D'Arcy Power (*Brit. Med. Journ.*, December 4th, 1897) relates one in which spontaneous disappearance of the mass occurred subsequently, owing to an attack of inflammation in the part left behind; but, as one has indicated by the cases referred to above, this inflammation may not always lead to a satisfactory issue.

Case 5.—The last case I have to describe was an interesting one in which there was a solid fatty growth on the anterior thoracic wall, adherent to the skin which covered it in, and this in turn was invaded for a good portion of its extent by a cutaneous lymphangiomatous development, similar in characters to that which I alluded to in my first case.

The child, M. S., was æt. 11, and the growth had been noticed since she was two years old. It increased gradually in size, but gave no inconvenience till about two and a half years previously, when she was operated on by Mr. Stanley Boyd at Charing Cross Hospital. The mother stated that there was no sign of the mass after this procedure, but that it commenced to grow again shortly afterwards. On her admission to King's College Hospital in August, 1901, the swelling

extended vertically from the second to the fifth rib inclusive, and from half an inch to the right of the middle line to well into the left axilla. It projected forwards two or three inches, constituting a tumour rather larger than a fist; and towards its lower part could be seen the rudimentary breast, which was quite independent of it. In consistence it was soft, slightly lobulated and irregular; freely movable on the deeper parts, but the skin was adherent over it. Enlarged veins coursed over the mass, and the scar of the former operation ran transversely across its lower border. The skin over the greater part of it, and especially towards the axilla, was slightly warty and papillated, resembling in colour and appearance the lymphangiomatous developments already described. No enlarged glands were to be felt in the axilla, and the growth was quite painless.

The whole mass was subsequently excised, and as it encroached somewhat closely upon the pectoral muscle, which looked decidedly infiltrated, it was thought better to remove the sternal portion of that muscle, and to carry the incision well into the axilla, from which a somewhat enlarged gland was removed.

The exact nature of this case is certainly open to discussion. The microscopic report as to the cutaneous condition merely stated that it was a papillomatous nævus; but looking to the appearance of the lesion before removal, the total absence of any evidence of circulating blood, and the entire accordance of characters with those of demonstrated lymphatic nævi, one is forced to the conclusion that it must be placed in that group.

As to the main mass, the report stated that it was merely fat, and that no lymphatic or hæmangiomatous developments were present; it was, however, a large mass, and it is possible that the portion that might have demonstrated its dependence on a lymphangiomatous origin was not examined. That fibro-fatty growths are associated with lymphangiomatous developments cannot be doubted. Mr. Marmaduke Sheild showed a child to the Medical Society in 1893 ("Med. Soc. Trans.," vol. xvi., p. 305) who was the subject of what he supposed to be a congenital fibro-fatty growth. In the next year's "Transactions" (p. 334) the sequel of this case is related. An acute attack of inflammation supervened in the growth, which became enormously enlarged, hot, red, and œdematous, and in spite of careful nursing the child died. On post-mortem it was found that the greater part of the growth consisted of solid fibro-fatty tissue, but that towards the axilla it merged into a sponge-like growth, and finally into distinct cysts, the size of peas or grapes, filled with yellow serous fluid. Spontaneous inflammation had occurred, and the child had been able to withstand the inflammatory fever and exhaustion. I look on my case as akin to this, but that the transformation into a cavernous type of lymphangioma had not been reached. In such developments one sees an analogy to the lipomatous conditions which are sometimes found associated with the hæmangiomata.

ALBUMINURIA IN THE APPARENTLY HEALTHY.(a)

By SAMUEL WEST, M.D., F.R.C.P.,
Physician to St. Bartholomew's Hospital.

THE term "physiological" or "functional," as applied to this variety of albuminuria, was not to be commended, as it begged the very question which it was desired to prove. Moreover, under ordinary conditions physiological albuminuria did not occur, and when it did it was a transudation, not a secretion. The greatest importance was to be attached to the state of nutrition of the walls of the capillaries, and also to the presence or absence of high arterial tension. It had been stated that albumin might be demonstrated in the urine in everyone. This was not strictly true, but, at the same time, if an ordinary specimen of urine free from albumin as recognised by the usual tests be evaporated down, and the residue extracted, a trace of albumin might be found. The explanation of this was simple, as a certain number of cells from the urinary tract were generally present in the urine. Except in this limited sense, albuminuria was never physiological at all, but always pathological.

The cases could be divided into three groups:—(1) *post-renal*, or accidental, due to the contamination of the urine from the genito-urinary tract; (2) *renal*, (*a*) with obvious cause, as kidney disease, (*b*) without obvious cause; (3) *pre-renal*, (*a*) with obvious cause, as in fevers or heart-disease, (*b*) with no obvious cause. It was the albuminuria in which the cause was not obvious that the diagnosis of this special variety was made by exclusion—always a difficult matter. With regard to the post-renal class of cases, a tiny calculus in the kidney might lead to a transient albuminuria or hæmaturia, and nothing else, the condition completely clearing up with the passage of the stone. Temporary albuminuria might also be due to the passage of oxalic acid gravel, and it was also said that the strongly acid urine of acute gout might likewise give rise to the same condition.

Many different names had been given to this form of albuminuria. Most of them called attention to some particular feature of the complaint, or indicated its causal relationships, such as "occasional," "intermittent," "remittent," "cyclical," "postural," "dietetic," and so forth. All these might be met with during the convalescence from acute Bright's disease. The actual frequency with which the condition occurred had been variously stated, 10 per cent. being probably the approximate figure. Its importance and significance varied with age. It had been met with in new-born babies, and it was not infrequent in quite young infants, in which class one series of statistics showed that it was present to the extent of 40 per cent. This was rather high. In boys at school, the average was 20 per cent. Here, the cases were divisible into two groups: those who were florid, full-blooded, and with good pulse-tension, and those in which pallor with low arterial tension was a marked feature. The practical question was whether their school life should be interfered with. He thought that each case must be judged upon its own merits, and that continuance at school under medical supervision was the best course to pursue. In the young adult, the condition became of importance with regard to the question of life-insurance, or of entry into the Services or large business houses. The presence of albumin at all was a risk which the insurance office was justified in declining to take.

From the age of twenty-five to thirty the case-frequency of functional albuminuria was lowest. The gravity of the condition increased almost *pari passu* with every year, the mortality sometimes working out at nearly double that of healthy persons. The chief *crux* of the whole question lay in the difficulty of excluding latent disease of the kidneys, especially granular kidney. The curves of mortality of the two conditions were

(a) Abstract of Paper read at a meeting of the West London Medico-Chirurgical Society, on Friday, February 5th, 1904.

very close. He would lay down as a general rule that any albuminuria which was accompanied by arterial thickening was an indication of some granular change in the kidneys.

The practical application of these considerations with regard to life-insurance was that it was advisable to reject all cases of albuminuria above the age of forty, to load heavily those between thirty-five and forty, to add considerably between the ages of twenty-five and thirty, and to postpone and watch those cases occurring from eighteen to twenty-five. If arterial thickening were present at the same time, one should reject at all ages. It was of supreme importance to recognise that albuminuria was never physiological but always pathological, though not necessarily renal.

ADVANCES IN THE CHEMISTRY OF ALBUMIN AND THEIR CLINICAL IMPORTANCE (a)

By G. KLEMPERER, M.D.,
Professor of Medicine, Berlin University.

ALL albuminous bodies, the lecturer said, were not alike, but fell into different groups. We distinguished two large groups, simple and complex. The first group fell into three divisions, the albuminous, the globulins, and the phosphor-albumins. The two first-named were found in albumin and also in blood serum; cell protoplasm contained only globulin. In the albumin of urine there were both albumin and globulin, but in varying proportions, according to the nature of the disease. With ammonia sulphate the globulin was only precipitated with difficulty; it was large-grained. For this reason it was kept back by the epithelium in the milder kidney affections, and principally albumin, the finely granular, was excreted, whilst in severe kidney lesions more albumin was let through. The phosphorus-containing albumin (formerly so-called nuclein-containing) resembled the caseous material that fell from milk by acidifying and was present in yolk of egg and in vegetable foods. It was formerly believed that animal and vegetable albumin were identical.

Amido-acids were always given off from these albuminous bodies. They changed later into proprionic acids, butyric acids, valerianic acids, and succinic acid. The amido-acids were divisible into monamino-acids and diamino-acids, the former acting as acids, the latter having basic properties. To the former belonged amino-capronic acids (leucine), aminolactic acid (alaline), tyrosine, and cystine. Other chemical changes of albumin had been found, heterocyclic circles. These simple albuminous bodies combined with other groups, and so arose the complex albuminous bodies, the proteids. They belonged to the cell-nucleus, and were therefore also called nucleo-proteids; they consisted of three parts—*viz.*, one part phosphorus, one part nucleus, one part purin substance. The latter was the mother substance of uric acid and of xanthin. Pentose was also contained in it. By pairing with dextrose, glucosamum was formed from the nucleo-proteid. Mucin belonged to the glyco-proteids that were peculiar to some albuminous bodies. Finally, the proteids combined with iron chromate proteid. The denaturised albuminous bodies were to be considered as special bodies.

What did the body do with these albuminous bodies? They underwent hydrolytic changes, were albumosised and peptonised. But peptonisation was not a final change; peptone was only a passing step. Peptone had disappeared from the stomach after four hours; only amido-acids were found in the intestines. Peptone was not generally absorbed, but passed on into crystalline albuminous products, which were absorbed, and from which the organism again prepared the albuminous bodies. Cohnheim had shown that the splitting up into crystalline bodies was due to a ferment secreted by the mucous surface of the intestinal walls, which he called crepsine. It was possible also that a part of the peptones was absorbed as such.

This new doctrine of the previous splitting up of albuminous bodies before absorption had caused a complete revolution of the views as to the relation of albumin to internal tissue change. We must assume that the albuminous bodies that passed on with the tissue and body fluids as component parts were formed synthetically out of the crystalline division-products of the albumin contained in the food, and that therefore the body itself performed synthetic functions.

When the cell structure was completed, urea was first formed, and by intermediary tissue change. As a rule the intermediary products passed away quickly. But by disturbances the demolition of certain cells might come to a standstill, and thereby a number of diseases might be caused. Among these was a rare disease, alkaptonuria (urine of a black colour, especially when alkaline); it was a pronounced family disease. There was also amido-oxyphenylacetic acid, which the ferment readily changed into tyrosine (paraoxyphenylaminoproprionic acid). The ferment was absent, however, occasionally; then the demolition came to a standstill, when we found the above-named material in the urine. Cystinuria also belonged here, and this was also a family disease; here the ferment necessary for the demolition of the cystine was absent.

Diabetes was more difficult of explanation. Here the sugar formation, the remaining at a lower stage of decomposition, was a chemical anomaly. Whence came the sugar? Not from the pentose and not from the glucoamine. It must be formed from the albumin itself, from the mono- and diamino-acids; glycosis arose and remained with the patient.

Another disease was the adiposity of anæmia. Here, without doubt, the fat developed out of the albumin. Fatty acid was also formed from CH_2, as also oxybutyric acid out of the fat.

The prostatic group of albuminous bodies was connected with uric acid. If the process became stationary at this stage, we had the symptoms of gout.

We had, then, the so-called autolytic processes in the body. Acetolysis occurred when something in the organism died off; a better name, therefore, was the necrochemical processes.

(a) Abstract of Address delivered at the Medical Society, Berlin.

The Plague.

THE following telegram from the Officer Administering the Government of Mauritius has been received at the Colonial Office:—"For the week ending January 28th, 28 cases of plague, 18 fatal."

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXXII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

WOODHURST SANATORIUM, DORKING.

As our series of articles has already abundantly shown, there is no dearth of excellent sanatoria for consumptives in this country. In almost every part of the British Isles well-equipped and wisely-managed institutions are now available. Indeed, for the wealthy sufferers the supply is in serious danger of altogether exceeding the demand. But for the poor the case is very different. For the pauper class adequate hygienic treatment is sadly lacking, although in certain districts efforts have been made recently to provide means for the carrying out of "open-air" methods. For the majority of these State-maintained consumptives the ordinary workhouse infirmary is the last and much-dreaded resort. While it is only right to acknowledge the immense prophylactic service rendered by these Poor-law institutions, it is necessary to remember that for the greater number of cases these infirmaries are unsuited to the needs of the phthisical. The hospitals and sanatoria supported by voluntary contributions or maintained by philanthropic effort are inundated with applicants. Recently, by a wise combination of county, municipal, and individual effort, certain establishments have been brought into being, and go some way to meet the wants of the comparatively poor. In most cases these attempts to deal with the needs of the indigent phthisical worker have been somewhat disappointing. To secure efficient hygienic management, considerable expense is necessarily incurred, and it is exceedingly difficult to provide food and the other requirements of "natural" treatment at such rates as can be met by most members of the working class. And perhaps the sufferers most to be pitied are those young females who, even when in full health, can barely earn sufficient for daily needs, and when overtaken by disease are dependent on the support of relatives or the benevolence of friends. It is to meet the requirements of this class that the sanatorium at Dorking has been established. It is restricted to females, and accommodation is provided for sixteen cases.

Woodhurst is situated on Tower Hill, on the borders of Dorking, in characteristic Surrey scenery. The sanatorium consists of a commodious, square, thoroughly well-built and good-looking house, originally intended for a private residence. By slight adaptation the building has been rendered suitable for its present purpose. The hall, stairs, and landings are extensive, airy, well-lighted, and allow free circulation of air throughout the establishment. The rooms are large, lofty, well-placed, and with good windows. In most instances three or four patients share the same bedroom. There are, however, certain rooms available, if necessary, for single patients. All parts of the house appear neat and clean, and present evidence of knowledge well applied, and ever active thoughtful management. The dining-room is good, and there is reasonable accommodation for rest and recreation.

The grounds, although not very extensive, are pleasingly laid out, and offer facilities for graduated exercise and suitable rest in the open. There is a well-designed shelter open on all sides, and here some of the patients spend a great part of every day. The grounds adjoin the famed Glory Woods, which are some forty acres in extent, and to these the patients have free access by a private entrance. A small but ventilated glass-house provides accommodation in wet weather.

A natural system of ventilation is, of course, maintained throughout. Heating is provided by means of open fires.

The sanatorium stands in its own grounds, and is separated from the road by a stone wall. The soil is sand and gravel. The house and its grounds are protected and yet allow of free exposure to sunlight. From the windows of the house and from certain parts of the grounds, extensive views of very beautiful undulating country can be obtained.

Woodhurst is within the parish of Dorking; the sewerage is good, and gas and water are provided by the town.

At the time of our visit of inspection we were accompanied by the visiting medical officer, who informed us that the cases were treated in accordance with the generally accepted principles of modern hygienic treatment. No special or exceptional form of treatment is employed.

The sanatorium is a proprietary one. Although a non-medical management cannot be considered the best, the arrangements in the present case appear to provide for the needs of a class whose wants are too apt to be forgotten. There is no resident lady doctor, but Dr. Mary McDougall, of Croydon, acts as visiting medical officer, and Dr. J. D. Rawlings, of Dorking, attends in cases of emergency. The nursing is directed by the daughter of the proprietor, Miss Wright, who has had many years' experience of general nursing, and since 1898 has devoted her attention entirely to the nursing of consumptives, and has thus had considerable experience in the management of these cases.

As we have already indicated, Woodhurst meets a want in providing a sanatorium for female cases at comparatively low rates. The terms are from one and a half to two and a half guineas weekly, according to bedroom accommodation, but drugs and laundry are not included.

Dorking may be reached by either the South Eastern and Chatham Railway or the London, Brighton, and South Coast Railway. The station of the former is the most convenient for patients, but is a mile and a quarter from the sanatorium. A conveyance is provided by arrangement.

CENTRAL MIDWIVES BOARD.

AT a meeting of the Central Midwives Board held on January 28th, 1904, Dr. F. H. Champneys in the Chair, the following business was transacted:—

1. On the recommendation of the Standing Committee, the Board adopted three sets of questions to be addressed respectively to those applying for approval or recognition in the following capacities: (*a*) Institutions applying for approval of their certificate, or for recognition as approved institutions under Section C 1 of the rules. (*b*) Registered medical practitioners seeking recognition as teachers under Section C 1 (3). (*c*) Certified midwives applying to be approved for the purpose of signing Forms III. and IV. under Section C 1 (2).

2. The following applications for recognition as approved institutions under Section C 1 of the Rules were granted: National Maternity Hospital, Dublin; Edinburgh Royal Maternity and Simpson Memorial Hospital; City of London Lying-in Hospital.

3. The following application for recognition as a teacher under Section C 1 (3) of the Rules was granted: John W. Fordham, jun., M.R.C.S.

4. A letter was read from Dr. E. Hastings Tweedy, the Master of the Rotunda Hospital, Dublin, calling the attention of the Board to the practical impossibility of pupil midwives trained in the Rotunda complying with the requirements of Section C, Rule 1, Subsection 1 (personal conduction of twenty cases), and Subsection 2 (ten days' puerperium). It was hoped that the curriculum of the Rotunda might be accepted as an equivalent to the course of training prescribed by the Rules, or that such exception or modification might be made as would enable the Rotunda nurses to qualify for the Board's examination. After consideration of the subject, it was unanimously resolved: "That having considered the letter addressed to them by the Master of the Rotunda Hospital, the Board regret that the suggested alterations were not brought to their notice before the Rules were sent to the Privy

Council, as, having been approved by that body, it is impossible for the Board to alter them."

5. A letter of similar purport was read from Professor Byers, physician to the Incorporated Belfast Maternity Hospital, and a copy of the foregoing resolution was ordered to be sent in reply.

6. After consideration of applications for certificates, the names of 1,040 women were passed under Section 2 of the Act, and ordered for entry on the Roll. Of this total, 269 claimed as holding the certificate of the Obstetrical Society of London, 14 that of the Rotunda Hospital, 26 that of Queen Charlotte's Lying-in Hospital, 14 that of the Glasgow Maternity Hospital, 14 that of St. Mary's Hospital, Manchester, 2 that of the Liverpool Lying-in Hospital, 1 that of the Edinburgh Royal Maternity Hospital, 1 that of the City of London Lying-in Hospital, and 699 were admitted as having been in *bonâ fide* practice for one year prior to July 31st, 1902.

THE STATE REGISTRATION OF NURSES.

A GENERAL meeting of the members of the Royal British Nurses' Association was held last week in the rooms of the Medical Society of London to consider the draft of a Bill upon the State Registration of Nurses, when several important amendments were made, and at the end of the meeting the following resolution was passed :—

"That the draft Bill, as amended, be approved, and that the Executive Committee be directed to take steps as they may think necessary to have it submitted to Parliament."

1. Three registered medical practitioners to be appointed for terms of three years. Two to be appointed by the Lord President of the Council, and one to be appointed by the British Medical Association.

2. Three persons to be appointed for terms of three years by the Lord President of the Council, one to represent England, one to represent Scotland, and one to represent Ireland.

3. Three representatives to be appointed for terms of three years, one to be appointed by the medical Director General of the Navy and the Medical Director General of the Army conjointly, one by the Royal Nurses' Association, and one by the Queen Victoria Jubilee Institute for Nurses.

4. Five fully-trained nurses, who shall be matrons or lady superintendents of hospitals or Poor-law infirmaries, with training schools attached, to be elected for terms of three years, one to be elected by the matrons and lady superintendents of Metropolitan hospitals, one to be elected by the matrons and lady superintendents of Metropolitan Poor-law infirmaries, one to be elected by the matrons and lady superintendents of provincial hospitals, one to be elected by the matrons and lady superintendents of hospitals in Scotland, and one to be elected by the matrons and lady superintendents of hospitals in Ireland.

5. Seven fully-trained nurses to be elected for terms of three years, three to be elected by nurses on the Register who are resident in the Metropolis, one of whom shall be a mental nurse and one a fever nurse, two by nurses on the Register who are resident in the provinces and Wales, one by nurses on the Register who are resident in Scotland, and one by nurses on the Register who are resident in Ireland.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD IN THE ROYAL COLLEGE OF SURGEONS ON FRIDAY, JANUARY 29TH, 1904.

The President, E. H. TAYLOR, M.D., F.R.C.S., in the Chair.

AFTER a few introductory remarks by the PRESIDENT, who returned thanks for his election to the position of President of the Section,

Dr. R. ATKINSON STONEY read a paper, entitled "The Anatomy of the Pelvic Fascia, with Special Reference to its Surgical Importance." He described a new method of demonstrating the connections of the visceral pelvic fascia, by hardening the subject in formalin, and then having made a mesial section of the pelvis, dissected the prostate and bladder out of their fascial envelopes. By means of specimens dissected in this way, and drawings and diagrams made from them, he showed that the visceral layer of pelvic fascia, instead of dividing into three layers as usually described, really gives off three complete sheaths, two in a downward direction surrounding the prostate and rectum, and one in an upward direction surrounding the bladder; and that each of these is complete in itself, and in no place does one layer of fascia enter into the formation of more than one of these three sheaths. He also pointed out that the visceral layer of pelvic fascia meets the urogenital apparatus at the vesico-prostatic junction, and the alimentary canal at the junction of the rectum and anal canal.

Sir Thomas Myles, the President, Professor Fraser, and Professor Dixon spoke.

Dr. HAROLD PRINGLE exhibited a dog on which he had performed Pawlow's "gastric fistula" operation. The object of the operation is to produce a stomach-pouch which is made to open on the surface, while the remainder of the stomach is left to perform its digestive function as usual. The pouch is formed in such a manner as to retain its nervous connections intact. Some lantern slides were shown illustrating the operation, and others giving the results of experiments, which showed that the juice secreted by the stomach-pouch varied in amount and rate of secretion, corresponding with the results already published by Pawlow.

The President and Professor Thompson spoke.

Dr. HENRY M. JOHNSTON gave a demonstration on the making of blood films by a new method. He also showed specimens of films stained and unstained. His apparatus is exceedingly simple, and is already in the hands of a firm of instrument makers. A complete account of this apparatus and method will shortly be published.

The meeting then adjourned.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

QUARTERLY MEETING HELD ON FRIDAY, JANUARY 29TH, 1904.

MR. BARK, of Liverpool, President, in the Chair.

CASES SHOWN.

MR. MAYO COLLIER showed a case of intermittent nasal obstruction, and cases illustrating stages of progressive deafness. The PRESIDENT said that the foregoing cases would be discussed in connection with Mr. Mayo Collier's paper later.

Dr. KELSON showed a case of laryngitis in a girl.

Dr. DUNDAS GRANT asked if there were any signs of hysteria, and remarked the enlarged tonsils and ventricular band phonation.

Mr. MCDOUGALL (Liverpool) suggested that the tonsils be removed and thus the neurotic element eliminated.

Dr. KELSON, in reply, said that he intended removing the tonsils and that he had not noticed any nervous tendencies.

Mr. STUART-LOW showed a series of cases of AURAL SEPSIS TREATED BY MEANS OF KELVOLIN VAPOUR, and the local application of pure kelvolin. Mr. Stuart-Low said that it would be agreed that bacteria kept up the continuation of the sepsis, and that this persistence is aided and abetted exceedingly by the peculiarly intricate anatomical arrangements pertaining to the tympanic cavity and its accessory recesses. It is passing strange, therefore, that with a pathology clear and explicit, as established by brilliant bacteriological research, the best means yet arrived at to combat bacillary ravages in this special region should be so ineffectual when put to the test in actual practice. After trying various substances very exhaustively, I

have selected kelvolin, a chemical product prepared by Messrs. Hay, Steven and Company, manufacturing chemists, Mary Hill, Glasgow, as the best. Kelvolin is a dark-coloured fluid of an oily consistency and slightly tar-like odour. It contains 40 per cent. of the homologues of phenol, and 35 per cent. of highly refined neutral products from coal tar. Kelvolin is prepared from highly refined materials and is free from resin and free alkali. Kelvolin is a very powerful germicide: the staphylococcus, the streptococcus, and anthrax spores are all easily destroyed by it even when it is much diluted. It has the further great advantage that so far from any irritating properties when applied to the tissues it has, in common with the phenols, an anæsthetic, numbing effect. It has, further, a softening action on incrustations and considerable penetrative power. Kelvolin is easily volatilised, and is again very quickly condensed upon anything held in the vapour. Kelvolin I have used extensively during the last few months on many cases of suppurative middle ear disease in various varieties and stages. I have used it in two ways—first, directly applied by means of cotton wool on a fine probe to granulations on the tympanic walls, and secondly, as a vapour. The vapour treatment I have found most efficient and satisfactory. I drive the vapour by means of an inflator into the external auditory meatus, and in this way it is forced into the farthest limits not only of the tympanum and attic, but backwards into the antrum and its adjacent cells, and downwards and forwards into the Eustachian tube. The patient plainly perceives it in the pharynx when the passage is sufficiently patent. I also force the vapour up the Eustachian tube through an ordinary Eustachian catheter inserted through the nose, and thus additionally insure that a thin layer of condensed vapour is spread over the entire interior of the middle ear and its accessories. Preliminary to using the kelvolin as just described, the interior of the ear must be prepared for the vapour by being freed from all discharges, this being accomplished by most carefully and thoroughly mopping it out with fine light probes carrying boracic wool, and in this way the surface is cleaned and dried for the deposition of the condensed kelvolin vapour, any granulations being touched gently and lightly with kelvolin. This preparatory process is not complete until aerial inflation by the Eustachian catheter and suction by means of Siegle's pneumatic speculum has been repeatedly performed, and every particle of secretion thus blown and sucked out has been carefully removed by most assiduous and painstaking mopping.

The PRESIDENT regarded these cases as very satisfactory and encouraging. Dr. DUNDAS GRANT said that he was favourably inclined to the method and would certainly try it in future. It seemed a valuable addition to the aurist's armamentarium. Dr. VINRACE could not concur with Dr. Dundas Grant, and wished to know if this method had ever succeeded where the usual treatment had failed? Dr. JOBSON HORNE would like to learn something of the bactericidal powers of kelvolin vapour. Dr. KELSON said the cases shown were very satisfactory. He would like to know if there had been any failures. Mr. NOURSE said he had been very much impressed by the ready way in which cases yielded to this treatment when other remedies failed.

Mr. STUART-LOW, in reply, thanked the President and Fellows for their kind reception of the subject. All the cases shown had been under the usual methods, some for years before coming under the treatment. Two of the cases shown were Dr. Jakins' patients, and both were instances of intractable discharge. Cultures were always taken before using the vapour, and then it was pushed until the culture was negative. There was no doubt about the germicidal power of kelvolin vapour—even the staphylococcus succumbed to its influence. There had been no failures, but when many granulations were present, shielding the seat of the mischief, the treatment was necessarily more prolonged.

Mr STUART-LOW also showed a case of nasal polypi in a boy, æt. 7. Prof. Hajek, of Vienna, had visited Dr. Dundas Grant's clinic and seen this case. He had never seen polypi in so young a subject and said sarcoma was likely.

Dr. WYLIE showed a case of primary hard sore on the lip of a woman.

Dr. JOBSON HORNE said such cases were uncommon, but he had seen three in five years. Mr. C. NOURSE remarked on the difficulty in tracing the primary infection often. Dr. DUNDAS GRANT said that sometimes the primary infection was on the tonsil and not interpreted until the mucous patches appeared. Dr. JOBSON HORNE said one of his cases was on the lip and then on the conjunctiva. Both at the casualty ward of St. Bartholomew's Hospital.

Dr. WYLIE showed a case of neoplasm, probably malignant, of the œsophagus, causing paralysis of both vocal cords.

Dr. LODGE (Bradford) said he had a similar case. Death ensued from septic pneumonia after perforation of the trachea. Mr. BARWELL asked if abductor paralysis was present in the case. Dr. JOBSON HORNE asked the situation of the growth.

Dr. WYLIE, in reply, said the growth was in the very upper part of the œsophagus.

Dr. WYATT WINGRAVE showed a case of laryngeal disease (tuberculosis) in a man, æt. 30.

Mr. BARWELL asked if anti-syphilitic remedies had been given.

Dr. WINGRAVE said he could get no specific history. He was going to use anti-syphilitic treatment.

Dr. KELSON showed a case of eruption on the fauces.

The PRESIDENT said the case was very interesting and might be a mucous tubercle. Dr. MCDOUGALL (Liverpool) thought the case syphilitic, and advocated intra-muscular injections of mercury. Dr. WEIGHT said the hypodermic injections of arsenic and iron might be tried. Dr. KELSON said the case had altered, and at first looked like malignant disease.

Mr. BARWELL showed a case of syphilitic laryngitis.

Dr. WYLIE asked the dose of iodide of potassium given. Dr. LODGE advocated 60 grains of iodide of potassium three times a day. Dr. DUNDAS GRANT said he had a somewhat similar case under treatment now. It looked like a solid œdema. Iodide of potassium failed, but mercurial inunctions did good.

In replying, Mr. BARWELL said that he gave 75 grains of potassium iodide a day, but he was going to give larger doses. He did not think it was œdema.

The PRESIDENT showed a case of growth in the anterior commissure above the vocal cords.

Dr. WYATT WINGRAVE said chiefly innocent growths spring from this position. Developmentally there might be tags left, which had become myxœdematous. He suggested a microscopical examination of the growths. Dr. VINRACE thought the growth had been present a very long time. Dr. JOBSON HORNE had had a similar case. This he removed with a double curette, after Krause's principle. Dr. LODGE had had a similar case. He removed it with a snare without exactly seeing what was being done.

The PRESIDENT, in reply, said there was a good deal of dyspnœa occasionally. His experience was that fibromata were always single, while papillomata were often multiple.

Mr. MAYO COLLIER read a paper entitled

LATENT OR INTERMITTENT NASAL OBSTRUCTION.

He said that this affection, although extremely common, had been overlooked by rhinologists. To this condition he attributed many of the more chronic and minor ailments found in the throat, nose, and ear, and much of the neurasthenia and dyspepsia so prevalent. In enumerating the functions of the nose, stress was laid on the relations of respiration to digestion and the circulation. In pointing out the relation of the nose to the ear a diagram was exhibited showing the developments of the tubo-tympanum from the nose and mouth cavity formed out of the first branchial cleft. A suggestion was thrown out that the nose was the safety

valve of the brain by acting as a drain to the arachnoid cavity. Important relations between the eye, ear, voice, and emotions were all touched upon, and finally the importance of continuous nasal respiration was insisted on.

The President thanked Mr. Collier, and said that the discussion on the paper would be taken at the next meeting.

NORTH-EAST LONDON CLINICAL SOCIETY.

Meeting held Thursday, February 4th, 1904.

Dr. J. W. Hunt, President, in the Chair.

Dr. Fred. J. Tresilian showed (1) a case of osteo-sarcoma of the superior maxilla in a girl, æt. 15, in which the antrum was involved. A partial operation had been performed five years ago, and since that time the growth had been quiescent. (2) A married woman, æt. 27, with tertiary syphilitic ulceration of the cheek and palate.

Dr. G. P. Chappel showed an infant, æt. 2½, with enlargement of the abdomen, and signs of general rickets. An operation had been suggested to the parents, but was refused.

Mr. Herbert Carson considered that the protrusion of the abdomen was due to tuberculous peritonitis, in spite of the fact that signs of rickets were present. He thought that laparotomy was the best form of treatment.

Mr. Carson exhibited a specimen from a case of ruptured gastric ulcer. The patient was a girl, æt. 18, who had suffered previously from dyspepsia, but there had been no hæmatemesis. She was seized with abdominal pain at nine o'clock one evening, but medical aid was not summoned until the next morning. Laparotomy was performed eighteen hours after perforation, but, being moribund at the time, she sank under the operation. The perforation was a double one, the ulcers being situated at the cardiac end of the stomach.

The President remarked upon the great rarity of the occurrence of perforation in two adjacent ulcers, and suggested that the accident had happened at two separate periods of time.

Mr. Carson replied that perforation of one ulcer would not necessarily relieve tension in another, as on the operating-table the stomach was generally found to be distended, even after perforation. He believed that the most important prognostic factor in these cases was the condition of the stomach at the time of perforation rather than the interval which might elapse between that event and the operation.

Dr. A. J. Whiting showed three cases illustrating different types of syphilis affecting the nervous system. In one of them, a woman, æt. 60, the symptoms were largely spinal, but she presented one very remarkable clinical feature, namely, that her pupils, which did not react to light, *dilated* on accommodation. On closer inspection, a slight transitory contraction previous to the dilatation was observed. She had also commencing cataract in both eyes.

Mr. R. Philip Brooks remarked that the presence of a cataract would not in itself influence the movements of the pupils.

Dr. Whiting also showed a married woman, æt. 35, the subject of post-influenzal ulnar neuritis on the right side.

Dr. Arthur E. Giles exhibited specimens of some diseased ovaries which he had removed by operation. Two of them were cystic, and in both the pedicle had become twisted. The pressure-effects due to the mobility of one of them had led to the diagnosis of renal colic by the patient's medical attendant. The frequency with which a prolapsed ovary became cystic, thus necessitating its removal, was pointed out.

THERAPEUTICAL SOCIETY.

At a meeting of this Society in the Apothecaries' Hall, on January 19th, Sir W. Thiselton Dyer, President, in the Chair,

Professor J. B. Farmer read a paper on

SOME NEW DISCOVERIES RESPECTING CANCER.

He said that of the two theories of the causation of cancer either (1) from a parasite sporozoon, or (2) from stray cells, there was no real proof; but from his investigations with Messrs. Moore and Walker, it appears that cancer cells differed entirely from other ordinary cells of the body in their development. All somatic cells, when dividing, have their nuclei split into a definite number of longitudinal rods or chromosomes, while the chromosomes of reproductive cells are oval or ring-like in shape, and divide in a transverse manner. Further, their chromosomes are present in half the number of those that appear in somatic cells. Now cancer cells exactly resemble reproductive cells in their mode of division, and, like reproductive cells, have the power of destroying somatic cells in contact with them. This is seen in the embryo sac of plants. This heterotypical mitosis occurs in all malignant growths, but is never found in benign tumours. Sometimes the ordinary somatic cells of plants change into reproductive cells, and the causes of this alteration have to be ascertained by further investigations. The frequent anomalies observed in the malignant growths, while they obscure, do not affect the existence of the characteristic heterotypical mitosis. They are probably to be related with nutritional and other disturbances that are known to similarly affect the nuclei of normal tissues.

Sir William Thiselton Dyer thanked the author for his very valuable paper, which proved how useful the science of botany might be to the medical profession.

Dr. Wild considered the paper to be a most important one, and asked whether the heterotypical division of the nuclei was found in less malignant diseases, such as rodent ulcers or cartilaginous and thyroid tumours.

Dr. Rolleston said that cells had two different functions—either metabolic, increasing the tissues, or anabolic, destroying them; and that when cells increased in a tumultuous manner they became destructive to other tissues, as in malignant disease. He inquired whether the heterotypical division of nuclei was found to occur in the preliminary stage of mammary cancer.

Sir H. Beevor said that Begonia leaves produced new plants when bruised, and inquired whether the heterotypical division was found in their cells. He said that Sir J. Paget considered that cancer resulted from embryonic cells remaining in certain parts of the body till stimulated to increase.

Professor Farmer replied to the questions, saying that the cells of Begonia did not show the heterotypical division even when bruised, but that further investigation was necessary.

Dr. T. N. Kelynack read a paper on

SOME POINTS IN THE HYGIENIC TREATMENT OF PULMONARY TUBERCULOSIS,

based on a recent inspection of many of the British institutions for the care of the consumptive. He dealt with the evolution of the modern sanatorium, and indicated how such pioneers as Parrish, Bodington, MacCormac, and B. W. Richardson had to a great extent anticipated the modern application of hygienic measures in the treatment of phthisis. Particular attention was drawn to the pressing need for a systematised hygienic "after-cure" of consumptives. It was also shown that at the present time wide differences exist in clinical methods employed in sanatoria, and very considerable divergence in therapeutic practice. It was urged that serious effort should be made to secure some degree of scientific uniformity in clinical procedure, a measure of combination in scientific investigation and a suitable system of recording returns which would allow of a trustworthy comparison of results. In such a special form of medical work as sanatorium management it is most desirable that a faddish or quackish narrowing of outlook should be avoided, and a strict scientific spirit firmly maintained.

Dr. J. Gray Duncanson then read a paper on the

THERAPEUTIC VALUE OF SUPRARENAL GLAND PRODUCTS.

He touched briefly on the anatomy and physiology of the suprarenal gland, its medicinal preparations of

various forms, dry powder preferred for continuous internal administration; liquid extracts suitable for internal and hypodermic use; and, thirdly, preparations containing the active principle of adrenalin, first isolated by Takamine, a Japanese chemist, who gives for it the empiric formula $C_{10}H_{15}NO_3$. This is supplied pure or in solution 1 to 1,000, by Messrs. Parke Davis and Company. He contrasted this solution with three others on the market. He then gave an account of the application of these substances in the routine work of private practice. The usefulness of their ischæmic properties in ecchymosis of the eyes and other conditions, their hæmostatic qualities when applied directly to a bleeding surface, and, lastly, the value of adrenalin preparation in arterial hæmorrhage, when the drug does not in the first place reach the bleeding surface. He struck a note of warning as to the administration in hæmoptysis, citing cases where the pulse became hard and of high tension with continued hæmorrhage; but on discontinuing the treatment the pulse softened and bleeding ceased, application by means of the spray being the only justifiable course in such cases. In a case of diabetes mellitus, the glycosuria was increased while taking adrenal liquid, but decreased on stopping its administration. He concluded with an appeal for the official recognition of suprarenal preparations as therapeutic agents.

Dr. GLASSINGTON said that he has found adrenalin of great service in dental surgery, when hæmorrhage had occurred from the gums, and he proposed a vote of thanks to the author for his valuable and interesting paper. This was unanimously agreed to.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD WEDNESDAY, JANUARY 27TH, 1904.

J. COTTER, M.D., F.R.C.S.I., President, in the Chair.

THE PRESIDENT read notes of a case of perforation of the intestine successfully treated by operation. The patient was a girl, æt. 12, suffering from tuberculous peritonitis. On admission to hospital she was greatly emaciated, and suffered from extreme abdominal distension. The day after admission the abdomen was tapped, and a large quantity of pus escaped. Next day the abdomen was opened, and the peritoneal cavity found full of pus, having a fæcal odour, while fæces were found escaping from a small aperture in the transverse colon. The peritoneum was studded all over with tubercles. The aperture in the colon was sutured, and the cavity closed. Healing was slow, owing to the damaged condition of the peritoneum and the emaciated condition of the patient, but was ultimately complete, and the patient's weight increased in nine months from 4 stones to 7 stones 2 lb.

Dr. P. T. O'SULLIVAN read notes of a case of pulmonary tuberculosis treated by tuberculin. The patient was a young woman, æt. 21. The first two injections had no effect, but the reaction to a third injection was very marked, the temperature rising to 106·4°, and all the symptoms being aggravated. Only the greatest watchfulness saved the patient's life at this stage. On the other hand the effect of the injection was to cause the entire disappearance of tubercle bacilli from the sputum. No permanent advantage followed the treatment, which, even with the improved serum now being used, is of very doubtful benefit.

Dr. CORBY showed an external ear which he had removed from a man, æt. 60, for epithelioma.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 6th, 1904.

AT the Society for innere Medizin, Hr. Plehn showed a case of

ISOLATED MOTOR APHASIA.

The patient was a man who for eight years had been a colonial secretary in the German possessions in East Africa, and during that time had had about forty severe attacks of malaria and five attacks of blackwater fever. A disturbance of speech remained. Sometimes the expression for his ideas was not to be mastered, and sometimes the ideas themselves were absent; but he could always write fluently to dictation. In January, 1902, the patient returned to Germany and passed through an attack of blackwater fever; this left the speech still worse. A similar result followed a malarial attack in September, 1903. When the patient was admitted into hospital there was almost complete loss of power of expression as well as of repetition, but his power of writing to dictation was still perfect. The case was plainly one of isolated motor aphasia from disturbance in the cortical centre. The malaria was got rid of in hospital, the aphasia was taken in hand by Dr. Gutzmann, with an excellent result.

In severe acute malarial cases, symptoms of local trouble in the brain were not uncommon, such as paresis, fits, hæmianæsthesias, and coma. These, however, disappeared with the attack. In the present case the course had not been so favourable, but this was because they had not given the patient quinine at the height of the attack, but, following an earlier practice, only after the fever had subsided, whereby a permanent embolism had taken place through the malaria parasites.

Hr. Gutzmann remarked on the case that when the patient was first handed over to him he could not repeat words pronounced before him nor answer a question; but he could write from dictation, and could also read well. There were symptoms, therefore, of subcortical aphasia. It was specially remarkable that in trying to repeat sounds and syllables, there were spasms in the voice apparatus as in stammerers. These spasms rendered treatment very difficult, and they had not yet quite disappeared, but came on during inspiration. For the rest, the practice treatment had had good results, the repeating of words had improved and also spontaneous speech; but there was still a dread of speech.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 6th, 1904.

LEPRA TUBERO-ANÆSTHETICA.

AT the Gesellschaft meeting, Spiegler exhibited a boy, æt. 16, with lepra tubero-anæsthetica, who had come from Rio de Janeiro, in Brazil, two years ago to attend school.

His abode or surroundings had no connection or semblance of lepra to induce such a disease, nor did anyone suspect that the lad suffered from that affection. Two months after taking up their residence in the city the mother began to develop red patches on both arms, which were quite insensible to pinching or stabbing with pins.

When closely investigated it was found that the boy must have had the disease some five years prior to this time, as such oval patches, with elevated portions which were also insensible, were present on all the extremities. The microscope has confirmed the bacilli, which leaves no doubt as to the correct diagnosis of the case. He now purposes the application of the Röntgen rays as the most rational expectant treatment, which will be watched with great curiosity.

PSEUDO-LEUKÆMIA OR LYMPHO-SARCOMA.

Stoerk showed the members a few specimens of adenoid tissue taken from the intestines of different patients to prove that these growths are neither the result of leucocythæmia nor lympho-sarcoma, but somewhere

between these two morbid growths. The clinical phenomena accompanying this adenoid tissue found in the intestine are much about the same in all cases—*viz.*, Constipation alternating with diarrhœa, œdema in the lower extremities, universal lymphatic enlargement, colic, causing great resistance in the canal associated with blood in the stools, decubitus, and finally death from pneumonia.

The post-mortem subsequently reveals the hyperplasia of adenoid tissue in the *primam viam* as a white, spongy mass of nodular tissue having sometimes a polypoid attachment, in others confluent or ulcerative. The lymphatics are everywhere enlarged, and stand out prominently, not even excepting the spleen and intercellular tissues of liver and kidneys, which are usually much infiltrated. The marrow of the long bones is always found in a red condition.

Stoerk concluded by pointing out that this picture was neither pseudo-leucocythæmia nor lympho-sarcoma, but a transitional form which had not yet been clearly classified.

Bromoderma Tuberosum.

Matzenauer next presented a woman with bromoderma tuberosum of an obscure origin. The face was quite covered with pustules of a spongy nature, of a dark brown colour, having a white vesicular margin rising from a red inflamed surrounding. The urine was examined and found to contain two milligrammes of bromine in every 970 grammes of the urine. This patient can give no account of how this element was taken into the body, and it is therefore assumed that she had taken it in unconsciously by the food or drink in daily consumption.

Neumann agreed with the diagnosis of the pustules, and remarked that the differential diagnosis of bromacne was readily diagnosed from genuine acne by the site. Bromacne, as a rule, restricted itself to the temporal region, while acne proper was more diffuse, while its dark vesicular wall usually distinguished it from erythema nodosum.

Cardiac Surgery.

Weinlechner concluded the sitting by giving a long paper on surgery of the heart. Briefly summarised, he said injury to the heart by needles, pins, or other sharp articles passing into the body by the œsophagus was not a very uncommon occurrence, and should always be provided for. The usual advice of extracting the offending substance was criticised, and a long description of how to lay the heart bare given. His method is to insert the knife between the sixth or seventh rib outside the heart, carry the incision inwards to the sternum, then up the outside of sternum as high as required, probably to the third rib, finally outwards, thus making a flap that may bedrawn forwards as a hinge.

Time is an important factor, as the movement of the heart tends to tear or aggravate the wound, the longer it isallowed to remain. There are a number of other articles that may lie in the cardiac muscle for a long time without doing much harm; even needles themselves have lain long in this position without the patient experiencing any discomfort, and bullets or other pieces of metal have been known to lie for years without any untoward circumstance. He recorded four cases of stabbing wounds in the heart; only one was sutured in time to save life, the other three dying in forty-nine hours after the injury. The adhesion of the pericardium to the heart, and subsequently uniting with the thorax, leads to a difficult operation of resection or cardiolysis. In many cases the soft tissues only become involved, and thus often produce displacement. Experiments on animals for the latter defect have often been performed with perfect success. These experiments have even gone so far as repair of the bicuspid valve with perfect success. We are told that nineteen such cases have been so treated.

"Medicals as Pirates."

This is a title that is going the round of the medical journals in Vienna concerning Dover, from whom we derive Dover powder. For the information of their readers they tell how Dr. Dover discovered Alexander Selkirk, the subject of "Robinson Crusoe." Dr. Dover was born in Warwickshire, a pupil of Sydenham, and took his degree in London, but seems to have taken to the sea immediately after. Later he is represented as Captain Dover, sailing from Bristol for Spanish ports in 1709.

About this time he lands in the island of Juan Fernandez, where he discovers Alexander Selkirk, who had been left on the island four and a half years previously. The latter is taken on board and given charge of one of the craft. After this the town of Guayaquil is assailed, and a large amount of booty carried on board. Steering along the Peruvian coast, then round the Horn, and across the briny ocean, he reaches England in 1711. The booty realised 850,000 dollars, the greater portion of this belonging to Dr. or Captain (?) Dover. With this handsome dowry he retired to London, where he left the "Ancient Physician's Legacy" in 1733.

Hungary.

[from our own correspondent.]

Budapest, February 5th, 1904.

The Medical Profession and Duelling.

The movement against duelling is increasing in strength and importance from day to day. Persons of every rank join the new Union of Nonduellists, and at present they number nearly six thousand. Recently also members of the medical profession have entered the Union, and they are obliged not only to abstain from duelling, but even to refuse attendance at a duel when summoned.

The Care of Infectious Patients on Railways.

The official *Journal* publishes an enactment, edited by the Minister of Internal Affairs, according to which the carrying of patients suffering from cholera pestis, or from declared mania, is prohibited. Those suffering from contagious diseases, which are not so acutely conveyable to other persons, will be allowed to sit in railway carriages only when every hygienic precaution is taken. Patients suffering from small-pox, diphtheria, dysentery, typhoid, lepra, &c., must be separated in locked cars, and these must be furnished with the signature "infected passengers." Patients suffering from whooping-cough can be admitted into ordinary cars, but they must be separated (within the car) from the healthy passengers.

Food Poisoning.

The *Orvosi Hetilap* reports a triple case of fatalism. Dr. Mirelli was summoned to a family, where six hours after the consumption of sausages the symptoms of acute enteritis had set in, with general malaise, nausea, gastric pressure, vomiting, slight diarrhœa and headache. The symptoms of specific intoxication appeared thirty-six hours afterwards. Sight troubles, diplopia, paralysis of the upper eye-lid; the secretion having ceased, the conjunctival membranes became dry and insensible, pupils dilated, the accommodative power was gone, deglutitional troubles on account of paralysis of the throat, and total dryness of the

mucous membranes were the further consequences. Owing to the latter, speech became difficult, followed by schuria; retarded pulse-beat became increasingly marked. The sensorium was, however, always normal, temperature likewise. Treatment by powerful irrigation carried out through nutritive enemas was resorted to, and in order to counteract the dryness of the skin and mucous membranes pilocarpin was administered subcutaneously.

THE PHONENDOSCOPE IN MEDICINE.

Dr. Erdös is of opinion that this instrument will become, with time, as indispensable to the physician as the knife is to the surgeon. The speedy advance in surgical technique has, to a certain extent, obstructed the field of internal medicine, and it is undoubtedly owing to this fact that medicine has need of good and practical instruments. The introduction of the phonendoscope into practice marks a distinctly forward movement, and Dr. Erdös, having made extensive experiments, has arrived at the conclusion that the phonendoscope will be found most useful in the incipient stage of pulmonary tuberculosis, because even the weakest *râles* can be heard therewith, and sometimes this symptom alone is sufficient for diagnosis, which is an important advantage, because the earlier pulmonary tuberculosis is diagnosed the greater the probability of cure. Secondly, he has found the phonendoscope to be of great service in cases of obese women, in whom the deep fatty pillow renders auscultation impossible. Even in these cases the phonendoscope conveys clear sounds to the ears. In Austria-Hungary the Bazzi-Binnchis phonendoscope is generally in use (made by Martin Wallach's Nachfolger in Cassel, Germany). This instrument has the great advantage that its sensibility regarding the conveyance of sounds can be regulated according to the acoustic requirements of the physician.

Operating Theatres.

ST. THOMAS'S HOSPITAL.

NEPHRECTOMY FOR HYDRONEPHROSIS.—Mr. BATTLE operated on a married woman, æt. about 35, for a tumour in the right side of the abdomen, which was regarded as a hydronephrosis. Ten years before admission the patient had experienced an attack of pain in the right side of the abdomen, which had necessitated treatment in a hospital, where operation had been suggested but refused. The attack was a painful one, and lasted for some days, but was not characteristic. Three years afterwards she had another attack of a similar character, and again refused operation. Within the last few months she had suffered from some pain in the right side of the abdomen, and had noticed swelling. Dr. Ecklin, who had sent the patient to Mr. Battle, considered the case one of hydronephrosis, and had advised the patient to undergo operation. The woman's general condition was good and the amount of urine regular and without evidence of disease. On examination of the abdomen a large rounded swelling was evident in the right side. This distinctly fluctuated and was without tenderness or pain. It extended from the iliac fossa, under the ribs, and from outside the umbilicus into the kidney region. The patient was kept under observation for some days, during which time there was no further development of symptoms and no change in the size of the swelling. At the operation an oblique lumbar incision was made, as is usual in cases of nephrectomy, and the kidney exposed. The tissues immediately over the kidney capsule were a little œdematous and adherent to the capsule, but not forming together with it any great thickness of envelope. A trochar and cannula were passed into the tumour, and the contents evacuated. These consisted of a very large quantity of brownish fluid, containing abundance of cholesterin, of which six and a half pints were collected. The opening was made larger and the interior of the cyst explored, its extension upwards being more than was anticipated. The cyst was now separated from the capsule by means of the finger of the hand cased in a cotton glove. Its wall was, however, so very thin and friable that this separation was a matter of great difficulty. When forceps were placed on it in order that traction might be exercised, it tore away and a fresh start had to be made, and although great care was employed in the upper part towards the anterior aspect, the peritoneum was so adherent to the thin capsule that an opening of some size was made into the peritoneal cavity. It was found that the separation of that part of the capsule of the tumour which extended under the liver was attended with some hæmorrhage, but at no other part, not even in the neighbourhood of the hilum, was there any vessel of importance. During the separation two calculi were found in the cyst, both oxalate of lime stones, one, the smaller, impacted probably at the entrance to the ureter, whilst the other appeared to have been caught at the entrance of a dilated calyx. Owing to the hæmorrhage from the vein on the under surface of the liver, some clots had passed into the peritoneal cavity, and some were removed when the hand passed through the opening in the peritoneum, but as even this could not be done effectually through an enlarged lumbar wound and the hæmorrhage continued from the under surface of the liver from a point which was inaccessible, and, moreover, the extent of the opening into the peritoneum could not be gauged, Mr. Battle decided to make another opening from the front. The lumbar wound was plugged with gauze, and, the patient having been placed on her back, an incision was made with its centre at the level of the umbilicus and about two inches to the right of it. At this point the rectus sheath was opened in front, the muscle retracted towards the middle line, and the peritoneal cavity opened. The opening in the peritoneum was found to be placed between the hepatic flexure and the liver, and was of considerable extent; through this the vein on the under surface of the liver which was bleeding could be seen, and as it was not likely that a ligature could be applied at the depth at which this was situated, even if the forceps would have held, plugs of gauze in strips were passed down to it, and pressure made over the bleeding point, the ends of the plug being brought out through the lumbar wound. The opening in the subhepatic region of the peritoneum was closed with silk sutures, the peritoneal cavity cleansed of clots, and the abdominal wound closed. Sutures were put in the lumbar wound so as to close the anterior part of it. Towards the close of the operation it was considered advisable to administer two pints of saline solution into the veins. Mr. Battle said that the operation had been an extremely difficult one, because of the peculiarity of the cyst wall and capsule of the kidney. In this instance the true wall of the cyst was not only thin, but very friable, and the capsule outside it was also very thin, so that it was extremely difficult to separate the two, especially in those parts where the distension was most marked. It seemed as if not only had there been but little hypertrophy of the capsule, but as if, in addition, there had been some slight inflammatory change in it which had rendered it more easy to tear. The adhesion of the peritoneum in front was so dense that, even after removal of the cyst from the body it was hardly possible

to complete stripping away of the thin portion still adherent to it. The presence of the calculi, he thought, explained the origin of the cyst, complete obstruction of the ureter having occurred with suppression of secretion from that kidney. The presence of the calculi also accounted for the definite attacks of pain from which she had suffered, but it was not possible to be certain of the cause until these were found.

The plugs were removed forty-eight hours later, and the patient has made an uninterrupted recovery.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 10, 1904.

CORONERS AND MEDICAL WITNESSES.

Certain changes of procedure which have taken place during the last year or so in one of the Metropolitan Coroners' Courts demand the careful attention of the medical profession. For a long time past it has been notorious that the London County Council has been opposed to the existing system whereby the Coroner has called in the medical man who last attended the deceased person, as subject of inquiry, and who has been usually deputed to perform the post-mortem examination, when necessary. Failing any medical attendant, either regular or casual, the Coroner has usually called in some medical practitioner in his district. In cases of unusual obscurity there has never been any great difficulty, so far as we know, in obtaining any additional amount of expert medical and other scientific evidence that might be rendered desirable by the exceptional nature of any given case. The Coroner has full powers in the calling of evidence, and the machinery of his Court is so absolutely under his individual control that he may adjourn an inquiry month after month, if necessary, for the clearing up of doubts and difficulties. This plan has hitherto answered well enough. The average medical practitioner is able to bring to bear upon individual cases a common-sense knowledge that is trained to the close weighing of essentials in the light of available details. Were he the most ignorant of men, his views as to the probable cause of death in the case of a given patient who had been under his care during life would be of far more value than the opinion of a laboratory expert founded upon the facts of a post-mortem examination and a theoretical knowledge of medical practice. Yet it is to the latter that Mr. Troutbeck, the Westminster Coroner, presumably acting under pressure from the London County Council, pins his faith. Cases coming within Mr. Troutbeck's jurisdiction are no longer handed over to the local medical men immediately concerned, but to a quasi-official, for whose existence we have failed to find any legal warrant, who is styled "pathologist to the London County Council." That position is filled by Dr. Freyberger, who, although assuming the position of an "expert," we understand performs the duties at a far lower fee than that demanded by men whose authority is usually regarded as "expert." Indeed, we believe one of the considerations advanced by the County Council in urging the employment of an expert is the economy effected as against the fees paid to general practitioners. After all, the question of the rate of remuneration is a matter to be settled by the individual, although at the same time it is hard that a poor profession like that of medicine should suddenly be deprived of so large and legitimate a source of income by underselling—which may or may not be defensible—on the part of their own cloth. For ourselves, we do not for one single moment believe that the public will gain either in safety or in purse by the substitution of Coroners' so-called "experts" for ordinary medical practitioners; on the contrary, they will lose heavily by the lessened income and standing of their private medical attendants. We have not a single word to say against Dr. Freyberger's private or professional character and attainments. His present invidious position, however, renders it a duty to raise a sharp and decisive protest against the system of which he is, unfortunately for himself, the first exponent. Some weeks ago we commented upon a case in which a baby died after taking a "teething powder." The medical man in attendance thought the child died from a metallic irritant, probably antimony. Dr. Freyberger deposed there was no antimony in the body and on his evidence a verdict of death from natural causes was returned. We have since been informed that no mention was made at the inquest by Dr. Freyberger of the common cause of death from "teething powders," namely, the presence of perchloride of mercury from the slow conversion of calomel into the dangerous corrosive sublimate. Under these circumstances, we submit that the general practitioner who suggested the cause of death to have been a metallic irritant was likely to be nearer the truth than the gentleman who suggested "natural causes" for fatal convulsions. Then, again, as regards the Whitaker Wright inquest. Medical men were actually present at the death, medical men had been previously in attendance upon deceased, and a medical man was summoned from King's College. Mr. Troutbeck, however, in his wisdom, summoned none of these competent medical practitioners to the inquest, but handed over the post-mortem and report to

Dr. Freyberger. There is nothing, so far as we know, to point to the fact that a chemical analysis was made to show that cyanide of potassium was the cause of death. Corrosion of the tongue by cyanide of potassium seems to be an almost inconceivable occurrence. Yet that objective fact appears to have been prominently advanced in evidence. On the whole, we are inclined to think that if the relatives of deceased desire a re-opening of the inquiry there would be good grounds for making a demand to that effect. The question of death from natural causes is not to be disposed of on such incomplete and dogmatic assumptions as those which appear to have satisfied Mr. Troutbeck. In any case we think the time has come when the question of medical evidence in Coroners' Courts should be threshed out in the full light of publicity. Such a course will be likely to place the future relations of the public with the County Councils, the Coroners and the medical profession upon a sounder basis than that brought into existence by the recent arbitrary proceedings of the Westminster Coroner.

MEDICAL ADVERTISING.

IT is certain that we do not in this country at all understand the art of advertising ourselves, as it is practised by our brethren in other lands. Our representative associations have condemned such very wide publicity as is given by the insertion of signed bulletins in the newspapers, even where the patient is a person of public importance. In many quarters the items of fashionable intelligence which relate that "Dr. Blank has returned to 500 Dash Square, from a visit to Switzerland," or that "Surgeon Asterisk has left town for ten days," are also condemned. But the crimes of Clapham are chaste in Martaban, and actions that in England are "grossly unprofessional," or perhaps even "infamous," are in California peccadilloes of the mildest sort. We learn, for instance, that a professor in a San Francisco medical school, while nominally absent from home on his summer holiday, was in reality on tour through the neighbouring States in the capacity of what we can only describe as an operating showman. His visit to various towns seems to have caused all the interest usually roused by a travelling circus, and the newspaper clippings have been, with great kindness, collated and published by his admiring colleagues in San Francisco. We quote one or two of these, just to show the interest taken by the intelligent laity of the Western States in surgical affairs. "Sunday morning, about 9.30 o'clock, nearly every doctor in town was on his way to the County Hospital for the purpose of witnessing the first operation in the county with cocain anesthesia by the spinal column." It is further stated that "the reporter was present and witnessed the operation; when the hypertrophied prostate was removed, each piece was held up for the reporter's benefit." "The professor commenced by saying that he had operated on more than one thousand patients without one fatality." After this it is disappointing to read that "Mr. D—— was operated upon last Sunday by Dr. ——, who used his celebrated new method of spinal injection. The operation was entirely successful as far as the operation part goes, but D—— was an old and weak man and could not withstand the treatment." After this, the greatest sinners in the profession at home may, with some justification, in comparison with this gentleman, adopt a little of the mental attitude of the Pharisee in the Temple.

SIGHT-TESTING BY OPTICIANS.

THERE is no end to the encroachments that are made on the legitimate sphere of the medical practitioner by various trades and individuals, and strange as it may seem, not the least formidable and insidious of these come from those whom one regards as one's allies and assistants, rather than as one's rivals. Chemists prescribe, instrument-makers fit boots and trusses, and spectacle-makers test the vision, all without reference to the medical attendant. It is strange that the members of these worthy trades do not appreciate the fact that they depend so largely on the recommendation of medical men that, from the point of view of their own self-interest, it is dangerous to tamper with the goodwill of those to whom they must ultimately look for their supply of customers. But the medical profession is long-suffering, and experience shows that a policy of pin-pricks can be pursued to an unprecedented degree before it turns. The testing of vision in slight errors of refraction does not present any great difficulty to those acquainted with elementary optical principles, but there is far more than this in the procedure of the intelligent medical practitioner. Vision-testing with him is only one method that he adopts in the examination of the patient; it is not his be-all and end-all. Very likely he may suspect a defect in vision to be the first symptom of organic or functional nervous disease; or it may suggest albuminuria or diabetes; or, again, some deep-seated affection of the eye, such as detachment of the retina. These possibilities he bears in mind, and he proceeds from an examination of the eye to test the urine, to examine with the ophthalmoscope, or to try the knee-jerks. If he is satisfied that the defect is due to a mere error of refraction he prescribes glasses and sends the patient to an optician to purchase them. It may be that he adopts this procedure merely as a tentative measure whilst he is still uncertain of his diagnosis, and if the glasses do not give the expected relief, he examines the patient again and again to find the cause of their failure. Now all this can only be done by a medical man, that is to say, done efficiently, intelligently, and to the patient's best interest. It is no defence to say that the patient cannot afford the medical man's fees as well as the price of the spectacles. Few are the towns now in which a genuinely poor patient cannot obtain expert ophthalmic advice gratis, and in country districts the question does not arise, as there are no opticians and no ophthalmic surgeons. It cannot, therefore, be laid down too emphatically

that the testing of vision is a medical man's work, and a medical man's only. The spectacle-maker who takes on himself the responsibility of doing so is on a par with the prescribing chemist, and his business deserves to be tabooed by all the practitioners in the neighbourhood. All medical men, of course, do not undertake to test the sight with lenses, but nowadays there are very few places in which a colleague with the requisite skill and apparatus does not reside. To him the patient can be sent. Now, foolish and ill-advised as it is for a spectacle-maker to test the sight on his own account, it is a far more serious matter when the Company from which he receives his certificate support him in his pretensions. This, however, is what the Worshipful Company of Spectacle-Makers are gravely proposing to do. This ancient body have a committee sitting to inquire whether it would be well to include sight-testing in their examination for opticians, and to advise how it could best be carried out if they decide to institute it. It seems that by their Charter the Company have the privilege of conferring some right of this kind, but such a right is surely an anachronism in the twentieth century, when all that sight-testing involves is, or should be, understood by them. If the Worshipful Company should see well to authorise their diplomates to enter on this foolish and dangerous course, the medical profession has an effective counter. There is more than one firm now that will supply the profession with frames and lenses at trade prices, and thus allow the practitioner not only to charge a fee for his examination, but also to supply the patient with spectacles at a profit on the article itself. We think it would be a pity if this became at all a general practice, for it would tend to lower the status of the profession, and it would introduce an element of commercialism which would be apt to conflict with a disinterested and impartial opinion. Still, if the legitimate province of the practitioner is invaded with the sanction and approval of the authorities in question, he has the remedy in his own hands, and it will be well for the Spectacle-Makers' Company to appreciate the fact. *Ne sutor ultra crepidam;* we as a profession are willing not to leave ours, and it is for the opticians to say if they will force us to do so. The business of a spectacle-maker is an honourable and worthy one; the medical profession has the highest respect for it. So long as he employs himself in his appropriate and familiar field he will receive the support and patronage of its members. If he wishes to come and labour in theirs, they will know how to act.

Notes on Current Topics.

N-Rays.

It is often stated that scientific men lack imagination; that they are dry-as-dusts and sticklers for accuracy; that they lack perception. As a fact, the want of imagination is a fatal bar to the achieving of eminence in science or in medicine. Its possession, indeed, is a necessary step in the maturation of the inductive proof. What some laboratory-workers may have needed in this respect has been supplied for them by the novelist, and the wonderful conceptions of Jules Verne and Mr. H. G. Wells are threatening to become the commonplaces of the present. The marvellous heat-ray of the latter romancer, used by the Martians in their combats with men, may not yet be available as a method of practical warfare, but rays of various potentialities are being discovered on every hand, emanating from the most unlikely objects, and in the most unlikely places. The discovery of a fresh set of rays by M. Blondlot was noticed in this journal at the beginning of last month, and already workers are beginning to find that N-rays are given off from many other sources than the human muscles and nerves. M. Meyer has found that plants and vegetables emit them, especially from their leaves, branches and roots. Mushrooms and non-chlorophyllous vegetables are particularly rich generators of this new luminosity. Stranger still are the observations of M. de Lepinay, for he has shown that the N-rays are produced by sonorous vibrations. He has been able to exclude any fallacy from rays given off by the articles used to produce the sound—tuning-forks, gongs, and hammers—and to show that it is the actual vibration of the air that is the productive agent. It is early days yet to test the therapeutical properties of the N-rays, but after the unexpected and astonishing uses of the X-rays and Finsen light one is prepared for almost anything. In the *Wiener klinische Wochenschrift* a case of œsophageal cancer, treated by radium passed down in a capsule at the end of a bougie, is reported, and whatever else may have happened Professor Gussenbauer has been able to feed his patient by mouth without artificial means. The science of radiography opens up vistas of treatment which, without being unduly sanguine, promise to strengthen our hands most materially.

Mrs. Eddy's Toothache.

There would not, in the usual way, be any particular cause for remark on the fact of an American lady suffering from the worst of "human doles." Toothache is an affection that spares neither the highest nor lowest in the land, and its agony has inspired the hand of the greatest English poet and the Scottish national bard to set down their impressions of the sensations it evokes. Undoubtedly toothache is hard to bear, and its pangs are none the less difficult to suffer in silence because of the paucity of sympathy that is meted out to the victim. Burns, at least, found it so. Faith can go a long way in curing hysterical paralysis and pseudo-angina, but it is very difficult to believe one has not got a toothache, when one feels its intolerable throbbing, burning, and starting. Of course the Christian Scientist knows that the pain is all imaginary, and that all that is needed is to believe that one has not got a toothache, and, hey presto! it is gone. Mrs. Eddy

doubtless tried very hard to believe she had not got it, but the twinges would not take "No" for an answer, and eventually she was constrained to do what ordinary people do under similar circumstances—go to the dentist. The dentist was of the earth earthy, and instead of telling her to go home whilst he practised absent treatment, betook himself to his forceps-case, and extracted the offender. Whether Mrs. Eddy let the secret out in a moment of thanksgiving is not recorded, but the whole of America soon became aware of the visit and its result, and instead of congratulating her on the happy issue out of her ills, it was heartless enough to accuse her of inconsistency. What will the Christian Scientists do now? They had to acknowledge recently that the infectious diseases did not fall within the scope of their system, and now (presumably) diseases of the teeth will have to be excluded also. If this process goes on they will soon find themselves limited to the treatment of neurotic affections, where every therapeutical plan has its successes and all have their failures. If they manage to cure a few of the sufferers on whom we have all tried our hands and failed, we will not grudge them their triumph, but as these sufferers are principally people who do not want to be made well, one fears they would not get many thanks for their pains.

X-Rays and Uterine Cancer.

IT is generally supposed among those who have not devoted special attention to the subject that the treatment of cancer by the X-rays is only practicable where the disease is situated superficially. Most of the instances reported up to the present have, indeed, been cases of epithelioma or rodent ulcer of the face, and but few attempts have been made to bring the rays to bear on any deep-seated disease. However, as far as the experience given by such attempts goes, there is every reason to hope that when conditions admit the application of the rays, their effect will be equally satisfactory wherever the disease is situated. That the difficulty of treatment is in the main a mechanical one is shown by the success obtained by Mr. Sinclair Tousey, of New York, in applying the rays to several cases of cancer of the cervix. His method of treatment consists of three procedures. He first, by means of a speculum, with the tube placed near the vulva, applies the rays directly to the cervix and the anterior vaginal wall. A primary exposure of five or six minutes was given, gradually increasing up to about twenty, with, of course, intervals for the tube to cool. The next procedure is to treat the body of the uterus through the anterior abdominal wall. The time of exposure was about nine minutes, distributed over the lower part of the anterior abdominal wall. The third part of the treatment consisted in the application of the high tension discharge by means of vacuum electrodes. A current strong enough to produce a four-inch spark was used, and the vacuum tube was moved from one part of the abdominal wall to another, keeping it in contact with the skin. The cases treated by Mr. Tousey were those in which surgical treatment had been impossible or had failed. While he expressed no opinion as to the possibility of a disappearance of uterine cancer, he has in every case produced a symptomatic cure. Pain has disappeared, the discharge has ceased, the offensive odour has passed away, and the tumour has decreased in size. These results are so encouraging that we hope to see modifications of Mr. Tousey's methods applied in the case of cancers of the stomach and intestine.

Pneumococcic Infections.

THOUGH it has long been recognised that lobar pneumonia is a part of an acute general infection, and not merely a local disease, yet there has not been sufficient attention directed to the other lesions which may accompany those of the lungs. The reason of this is, of course, sufficiently obvious, for of the local lesions the pulmonary almost always predominate, and are, as regards prognosis, by far the most important. It is necessary, however, for a fuller knowledge of such a common disease that all cases of pneumococcic infection elsewhere than in the lungs should be reported, and in particular is this so where post-mortem verification of the condition has been possible. In three cases recently published (*a*) from Johns Hopkins Hospital, the principal concurrent lesion was arthritis, though other serous inflammations occurred. It is curious that an organism such as the diplococcus of pneumonia, which always chooses a mucous region for its primary lesion, should affect the serous membranes almost exclusively in secondary infection. The joints affected are usually the larger ones—shoulder, elbow, knee—and the symptoms follow each other in the different parts with often a couple of days' interval. In two of the cases there was a pneumococcic endocarditis, and in two of them meningitis. It is, of course, well known that peritonitis is a common pneumococcic infection, and in animals is commoner than pneumonia. The more we learn about such diseases as pneumonia, enteric fever and diphtheria the more we see that their names only represent some of the commoner effects of what is in each case a general bacteriæmia.

Osteopathy.

THIS strange exotic has never yet taken root on our shores, though in America it flourishes like the green bay-tree. Perhaps it is from lack of initiative that we prefer sticking to the old quack methods for curing illnesses that the doctors have "given up" rather than try new ones. True "Dr." Dowie and Mrs. Eddy both have a little band of adherents in this country, but (like the coney) they are a feeble folk, and not very aggressive. So long as they content themselves with practising "absent treatment" on their friends they are not likely to do much harm—or good. But it is a little curious that this particular "pathy," instituted by that great bene-

(*a*) *Johns Hopkins Hospital Bulletin*, November, 1903.

factor Dr. Still, has not come to steal the hearts of those who have tried homœopathy, hydropathy, and what they like to call "allopathy," and found them wanting. Osteopathy takes itself very seriously in America; it has its colleges, its courses, and its diplomas. It even has its organs; one is modestly named the *Osteopathic World*, whilst the other adopts the presumptuous but more restricted title of the *Journal of the Science of Osteopathy*. Osteopathy seeks to remedy that "large class of cases where medicine is useless and surgery does not apply." This large class consists of those in which the free and natural flow of the fluids and forces of the body is interfered with by displacement and contraction of the parts, and somehow or other the cause of all the trouble in these cases generally centres in the spine. So the doctor of osteopathy concentrates his brain power (such as it is) on finding out which of the vertebræ needs treatment, and it appears that he is seldom at fault in discovering one or other that wants attention. Occasionally, however, the spinal column is normal, and then a "twisted rib" has to be rectified. Osteopathy has been defined for us by its exponents as "fixing up what is out of fix, with a full and comprehensive knowledge of the human body"; but if this be its function one fails to see wherein it differs in its aims from those of the modern orthopædic surgeon. The hold that this ridiculous system has in some States may be judged from the fact that a Bill to place its practitioners on a legal footing was only thrown out of the Pennsylvania Legislation recently after a hard fight, and its defeat was only accomplished finally owing to the large number (24) of physicians that had seats in the House. However much we may suffer from unfair competition in these islands, we have yet been spared the "particular addition" of the osteopath.

Endovenous Medication.

The resources of the art of therapeutics are not so comprehensive that one can afford to neglect a possible extension of the method of treating patients by direct introduction of drugs and fluids into the circulation. Transfusion of saline solution is the only attempt at all widely made in this country to fulfil this indication, and this is frequently only used as a last resource. A systematic attempt was made at the Belvidere Hospital, at Glasgow, about two years ago to bring grave cases of diphtheria rapidly under the influence of antitoxin, by injecting the serum into the median basilic vein, and the results published certainly gave ground for the suggestion made that this method promised a greater prospect of recovery than the usual one of injection into the subcutaneous tissue. But this plan of treatment has stopped here, except in a few isolated cases that have been reported. It seems, however, that it may have a wider sphere of usefulness. Not all drugs, by any means, are useful for endovenous injection, and in proposing to employ any particular one it is well to consider the effect it is likely to have on the blood as well as on the more remote tissues. Preparations of mercury, for instance, coagulate the blood by combination with its albumens, and although intra-muscular injections of mercurial preparations have proved very useful in syphilis, it is not without risk that they can be injected endovenously. There is one drug which has been tried and reported on very favourably in this connection, and that is atoxyl, an organic arsenical compound. Excellent and rapid results have been obtained in neurasthenia, Graves' disease, chlorosis, and hysteria, and both in combination with tuberculin and by itself it has been of distinct service in a variety of tuberculous affections. It is claimed by German writers that the method is absolutely safe if strict care is taken that the technique of the operation is aseptically conducted, and that no air is injected with the fluid, and that the inner coat of the vein is not wounded. One physician has injected into the same spot in the same vein no less than fifty times in succession. It will be interesting to see if this plan comes in vogue more generally, for as a means of bringing a patient rapidly under the influence of a drug it has no equal.

The Collection of House Refuse.

The spirited correspondence that has been going on in the columns of the *Times* on the above subject directs attention to what is an admitted evil, especially in large towns. That veteran reformer, Sir Henry Thompson, started the ball, and Mr. Mark Judge and others have kept it rolling. The time which most local authorities select for collecting refuse is when people are abroad in the streets, and when the dust that is scattered by the collectors can get into as many people's mouths and noses as possible. The method they employ of having, in many cases, open carts for the reception of the refuse ensures that the greatest practicable quantity of dust shall be blown about the thoroughfares through which the cart passes. In fact "dust-distributing" would be almost as appropriate an epithet for their methods as "dust-collecting." In these columns a few weeks ago it was pointed out in a leading article how potent a means for disseminating disease dust could become, and the remarkable drop in the death-rate that followed the prolonged rains of the last two summers was dwelt on as showing how directly dust is responsible for purveying germs to articles of food and drink. The local authorities who collect refuse are also the sanitary authorities, and if they show so little regard to the most elementary requisites of communal health, one feels inclined to cry *Quis custodiet ipsos custodes?* The only serious argument advanced in their defence is the old one of expense. There is something to be said on this score, but one cannot help thinking that it is a penny wise, pound foolish policy to go on with the present disgusting methods rather than ask for a moderate sum from the ratepayers to institute an effective and cleanly plan. The ideal one would require each house to have two portable

covered dust-bins; one to be used by the servants while the other was taken away by the collectors in carts to be emptied straight into the destructor. The ideal time for the round would be the early morning before people were astir, and this ought to be easily capable of arrangement, even under the present system. Till people take the matter up for themselves, and make the question an active one at the time of municipal elections, things will go on as they are. And what they are and what they might be differ *toto cælo*.

The Sale of Poisons.

THE Whitaker Wright tragedy has appealed immensely to the public mind, and various aspects of this remarkable case have been brought forward to emphasise defects in our legal system and the management of our courts of justice. But is there not a greater and more important lesson to hand? Does it not show a painful laxity in our law regulating the sale of poisons that a man can obtain, without inquiry, as many tabloids of potassium cyanide as he wishes? A chemist may not sell a drachm of laudanum without elaborate precautions, but the photographer can dispose of the most deadly poisons without any restrictions. It is remarkable that in the general chorus of discontent with many arrangements brought out by aspects of this case, that this—the most vital and important—should have escaped comment. On the other hand it may be urged that it would hardly be conceivable that any scheme of legislation could prevent a determined man, with unlimited resources at command, from obtaining a supply of any deadly poison he might require. For that matter, any man of average intelligence who possessed an elementary knowledge of chemical methods might readily make his own cyanide of potassium. In this way we are brought back to the familiar aphorism that it is impossible to make men moral by Act of Parliament.

Public Health Legislation.

IT is an encouraging sign of the times that the Government propose to introduce a Public Health Bill into Parliament this session. As it comes rather late in the King's Speech it is only to be expected that it will occupy the usual rank that public health proposals enjoy in Parliament, namely, that of third- or fourth-rate importance. Still, in a programme concerned with no large measure of acute interest it may have a better chance of being discussed and passed than if a number of big Bills were being introduced. What the Bill will actually propose to effect is a secret, but there are three matters that it certainly should deal with. The first of these is security of tenure and superannuation allowances for medical officers of health and sanitary inspectors. It is a gross anomaly that medical officers of health and their subordinates, outside London, should hold office practically at the caprice of the Council they serve, while their duties to the community are constantly bringing them into conflict with the private interests of members of the Council. This is a crying evil and calls loudly for remedy. Till medical officers are secure in the tenure of their posts, slum-property and over-crowding — to mention only two evils—will continue to flourish. The second subject urgently calling for Parliamentary action is to give effect to the recommendations of the Royal Commission of Sewage Disposal with regard to the pollution of oyster beds. It has been pointed out in these columns that the recommendation fails in an essential particular, namely, in not proposing to delegate the powers needed to bodies having medical experts to advise them. This fault is capable of remedy, but the public control of shell-fish sources is a pressing need. Finally, it may be hoped that the Government will see the necessity of adopting the suggestions of the London County Council with regard to the registration and inspection of manufactories of aërated waters. Dr. Hamer's report to the Council, published last year, disclosed a state of things existing in the smaller manufactories of these beverages that demands prompt and effective supervision. The clauses of the Bill will be awaited with interest.

The Exploiting of Disease.

A CORRESPONDENT in one of the daily papers has drawn attention to what he believes is a growing evil of the present day—namely, the eager desire on the part of the public to acquaint themselves with the mysteries of disease from the most varied aspects and in its most sordid details. He laments the ready gratification of this morbid appetite by a certain section of the Press, and expresses the opinion that disease may be itself produced by constantly dwelling upon its symptoms and manifestations. To consider the latter statement first, it is, of course, possible to induce symptoms of functional nerve disorders by auto-suggestion, for this process is well known to play an important part in the complex nervous mechanism of the hysterical. In this capacity it is much on a par with imitation, which often powerfully influences weak minds. The so-called "epidemics" of suicide may sometimes be traced back to one notorious example, the perusal of the details of which has upset the mental balance of less stable individuals. Medical students, on reading the account of a disease in a text-book of medicine for the first time, occasionally find it difficult not to believe that they are affected with the very complaint which they have been studying, to wit, the familiar example in fiction of the man who was positive that he showed symptoms of every disease under the sun, with the exception of "housemaid's knee." With regard to the first question, the dissemination of knowledge respecting the prevention and modes of infection of tuberculosis cannot be otherwise than beneficial, and, though it is to be regretted that premature accounts of reported "cures" of such a disease as cancer are published in this manner, the interest thus aroused should contribute, in some degree, to the earlier diagnosis of these malevolent disorders. We are

glad to think that the majority of newspaper readers are not morbid-minded and are, generally, only too ready to take hints and learn facts about any matter which threatens the health of the nation. *Omnia puribus pura.*

Guy's Hospital and Charges of Neglect.

The Southwark Guardians have formulated various charges of neglect against Guy's Hospital. The case that gave rise to these recriminations was that of a patient suffering from stricture and retention of urine. He was attended by the house surgeon in charge, and, as there was not a surgical bed available, he was sent in a cab to St. George's Workhouse, with a recommendation for admission. The unfortunate man died not long afterwards. The authorities of Guy's Hospital are credited with a "vigorous reply" to the guardians' charge of neglect. In the published newspaper report of the Treasurer's comments it is admitted that the case was one requiring admission as an in-patient. There was not room, however, and the Treasurer suggests that the public should subscribe to enlarge the hospital accommodation. It would be more to the point, however, to state if all the patients occupying beds at Guy's are persons whose means are sufficiently narrow to warrant their maintenance by a public charity. Further, whether any of the existing ward accommodation at Guy's is devoted to well-to-do paying patients. Thirdly, whether some of the chronic cases under treatment could not be weeded out of the wards to make room for others of extreme urgency. Guy's is a noble charity, but that fact does not make it perfect or place it above criticism. The ground advanced by the authorities that as Southwark contributes little to the funds of the hospital it is therefore not entitled to demand for relief seems to us to be absolutely beside the mark. If relief were to be accorded to districts in proportion to their individual subscription then Kensington and Grosvenor Square might demand to fill the wards of Guy's. On the contrary, the poorer a district, the greater its claims on a public charity. We cannot think the system of a hospital perfect if a man is sent away from the gates to die when his life might be saved by immediate surgical operation. The urgency wards of Guy's should, in our opinion, be at once extended at the expense of the ordinary ward accommodation.

"Premature Burial."

The curious and most essential feature about so-called "premature burial" is that it has never been shown to exist. To form societies to guard against this terrible phantom and to propose legislation against it is more "premature" than the wildest assumptions and random statements of its sensation-mongers. The literature of the subject is voluminous; but when subjected to a careful examination, such as would happen, for instance, were the statements in question brought forward as evidence in a court of law, they vanish like smoke into thin air. The many instances of alleged live-burial were examined by a medical man some years ago in a little book published by Messrs. Bailliere, Tindall and Cox. He came to the deliberate conclusion that no case of the kind had ever been substantiated. That is the scientific attitude, namely, that though live-burial is not impossible it has never been shown by incontrovertible proof to have occurred in any one single instance. We learn that a society established with the view of preventing this shadowy danger has drawn up a draft Bill with a view of making a personal examination of a dead body compulsory on the part of a medical man before he grants a certificate of death. That contention will doubtless meet with the approbation of most members of the medical profession.

PERSONAL.

The Opening Address of the eighty-eighth session of the Royal Army Medical College was delivered last week by Sir William Taylor to the lieutenants on Probation.

Dr. H. K. Anderson has been appointed University Lecturer in Physiology in the room of Dr. J. H. Langley, who resigned recently on appointment to the Professorial Chair.

Dr. Alban Doran has resigned the Editorship of the *Journal of Obstetrics and Gynæcology of the British Empire*, and Dr. T. W. Eden has been appointed to fill his place. It will be remembered that Dr. Doran took a leading part in the establishment of the journal.

Dr. Samuel Lloyd, on retiring from the medical officership of the St. Giles' Workhouse, was, on February 3rd, the recipient of a valuable silver salver, in token of the esteem in which he is held by all the Poor-law officials with whom he had been brought in contact.

Mr. Timothy Holmes, F.R.C.S.Eng., who has recently resigned the office of Treasurer of St. George's Hospital, will be entertained at a complimentary dinner at the Whitehall Rooms of the Hôtel Métropole on Saturday, February 13th, at 7 p.m. The Earl of Cork and Orrery will preside.

Sir David Palmer Ross, Surgeon-General of British Guiana, who has been seriously ill for some time past, has been granted leave on full pay until March 27th. His duties have been taken over by Dr. J. C. P. Widdup, one of the Government medical officers, who becomes Acting Surgeon-General.

The Annual Oration of the Hunterian Society will this year be delivered by Dr. J. F. Woods at the London Institution, Finsbury Circus, E.C., on February 10th, at 8.30 p.m. The Oration is open to all members of the medical profession, and the subject will be the "Psychic Side of Therapeutics."

Dr. Sidney Reginald Dyer, Medical Officer at Stafford Prison, has been appointed Principal Medical Officer of Dartmoor Convict Establishment. Dr. Dyer, who went to Stafford from Wandsworth Prison in 1900, will be succeeded at Stafford by Dr. Percy Mander, Deputy Medical Officer at Wandsworth.

Major Morgan has vacated his appointment as Medical Officer of the Duke of York's School, and has

returned to India. Owing to his efforts, the question of the removal of the school to healthier country quarters has been carried to a successful issue. This distinguished service to the Army and to the country certainly deserves public recognition.

THE late Mr. Powell Williams, M.P. for South Birmingham, who was seized recently with his mortal illness in the House of Commons, was married, in 1870, to a daughter of Mr. Bindley, a Birmingham surgeon.

DR. ARGYLL-ROBERTSON, Surgeon-Oculist to the King for Scotland, was the guest of the Cap and Gown Club at a farewell dinner held in the Royal Hotel, Edinburgh, on January 30th. Mr. G. W. W. Barclay, F.R.S.E., presided, and nearly one hundred visitors were present, including many members of the medical profession.

Dr. HENRY RICHARD KENWOOD, Medical Officer of Health and Public Analyst of the borough of Stoke Newington, has been appointed Professor of Hygiene at University College, London, in succession to the late Professor W. H. Corfield. Dr. Kenwood was Professor Corfield's assistant for twelve and a half years, and some six years ago was appointed assistant professor.

MR. JOHN ROBERTSON, M.D., B.Sc.Edin., until recently Medical Officer of Health of the City of Sheffield, and now holding a similar appointment in Birmingham, was entertained at dinner on January 28th by members of the medical profession and by his late colleagues on the staff of University College, Sheffield, and presented with various pieces of rare and valuable silver ware.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

SCOTLAND.

PROGRESS OF SMALL-POX.—During the last fortnight of January 316 cases of small-pox were intimated to the Local Government Board. The counties in which cases have occurred are Lanark, Ayr, Stirling, Renfrew, Banff, Dumbarton, Edinburgh, Fife, Kincardine, Linlithgow and Perth. The local incidence of the epidemic has so far been greatest in the burgh of Govan (5·23 per 10,000 of the population).

ABERDEEN ASYLUM.—The directors have under consideration the question of completing the building scheme undertaken in 1892, involving the reconstruction of the main building and the erection of new recreation rooms. A good opportunity for the carrying out of the work is offered by the impending removal of one hundred of the patients belonging to the city parish, which will do away with the overcrowding at present existing, and facilitate the rebuilding operations.

GLASGOW ROYAL INFIRMARY RECONSTRUCTION.—A public meeting has been held in Glasgow with the object of furthering the raising of funds for this object. The idea of reconstructing the whole building has evolved from the Diamond Jubilee scheme, which was restricted to the front block only. For some time difference of opinion existed as to the advisability of rebuilding on the present site, but the general view now is that it would probably be difficult to get a better site in all respects than the present one, and the question is now beyond the reach of discussion. The funds in hand include £86,500 ear-marked for the Jubilee memorial front, and of the £200,000 required to complete the building, £78,000 has been subscribed. At the close of the meeting it was announced that another £1,200 had been received, and a committee was appointed to promote the supplementary fund.

MORRISON LECTURES.—The present course of Morrison Lectures was delivered by Dr. John Macpherson, Commissioner in Lunacy, in the Hall of the College of Physicians, of Edinburgh during the last week of January. Taking as his subject, "Variation in its Relation to the Origin of Insanity and the Allied Neuroses," Dr. Macpherson devoted his first lecture to the laws of heredity, the extent of variation, and to the phenomena of genetic selection, regression, correlation, and the distribution of mental characters. He adopted the views of Wiessmann, which had received direct confirmation from Beard's researches, that descent is through the germ cells alone, and pointed out that the view that a child inherited directly from his father was a cause of confusion of thought about the matter. He next described the methods of the mathematical school of biological investigators, among whom Karl Pearson is so prominent a figure, and showed that psychical characters were distributed according to the same curve of probability as physical attributes. In the succeeding two lectures the idea of disease as a variation was elaborated; first, the conception of monstrositities of various kinds as variations being illustrated, and then the analogy being extended to idiocy, epilepsy, hysteria, and alcoholism. These variations had neither racial nor geographical limitations; some of them, like monstrosity, were not even limited to man, but occurred in the lower animals. Alcoholism was defined as a variation from the normal characterised by a craving for artificial mental states produced by drugs. In conclusion, the lecturer said that recent observations referred to showed that variation fell under the mathematical theory of probability, and if, as he thought he had shown, the neuroses he had been considering were constant variations, universally distributed throughout mankind and the lower animals, and hereditary, they could neither be due to chance nor to environment, but to genetic selection.

ALOPECIA AND DENTAL CARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The authorities upon whom "Medicus Senex" relies for his pronouncements on dental physiology are a good deal more out of date than mine; in fact, they are passed senility and are dead. More than forty years ago the late Sir John Tomes, the first dental physiologist to work in the light of modern science, overthrew the fancies of ancient pathologists by his demonstration of the true character of the hard dental tissues. Since then, no physiologist or pathologist with the least valid claim to authority has questioned the fact that enamel and dentine are incapable of physiological or pathological activity. Enamel contains a barely recognisable trace of organic matter; and the basic mass of dentine is almost as lowly organised. I quite agree with "Medicus Senex," and so does every dental physiologist, that it would be "bold to affirm a similar fact with regard to bone." Even the densest bone has a free permeating vascular supply, whilst the dental tissues have none. From other avascular tissues, like the cornea and cartilage, they are differentiated by the fact that they contain no cell elements capable of carrying on processes of nutrition. The physiology of enamel and dentine is beyond all controversy demonstrated, and is easily demonstrable. "Medicus Senex" will find the whole story in Sewill's "Dental Anatomy and Surgery," or in any similar book of the day. Once formed, the hard dental tissues can undergo changes only by action of external agents; to suggest the possibility of degeneration in enamel and dentine is absurd. The tissues are, however, often badly made, owing to interference with the process of calcification; and this may show itself in the external form of the teeth, as in honeycombed or spinous crowns, or in the typical syphilitic teeth of Hutchinson. These latter, I would say in passing, are extremely rare, not being present in more than 1 per cent. of affected children,

although other malformed teeth are often mistaken for them. A decadent subject may have defective dental tissues, but the causes have ceased to operate very early in life. The temporary crowns are all calcified at birth, and by this time the first permanent molars, incisors, and canines are far advanced in development. Then, again, the action of micro-organisms in caries does not in the least resemble the phenomena of diseases affecting vascular tissues, or of a systemic nature. Acid is the agent in dental caries, and the acid is produced by fermentation in organic matter, of course due to organisms. The organisms proliferate in the dentinal tubes, and are always found there in caries, but they are acting as external agents and not setting up a pathological process such as occurs in more highly organised structures. The analogue to alopecia among dental diseases would be premature shedding of the permanent teeth. This is not a common disease nor a characteristic of degenerates. Slow wasting of the alveoli accompanied by suppuration—pyorrhœa alveolaris—is a commoner disease. It occurs mostly in mouths singularly free from caries, and is by no means a disease of individuals physically inferior. This malady has many points of resemblance to sycosis, a fact which was noted some years ago independently by Mr. Jonathan Hutchinson and Mr. Sewill. I have taken some space in these explanations, and I trust you, Sir, will not think it excessive. I admit that the pathology of the teeth is the last thing about which the practitioner of medicine needs to be fully informed. It is impossible for any man to be a walking compendium of the whole range of medical science. But I would suggest that the solution of problems of pathology associated with the teeth is not likely to be promoted by writers who have not taken pains to make themselves properly acquainted with the fundamental facts of dental physiology.

I am, Sir, yours truly,

February 4th, 1904. M.R.C.S., L.D.S.

THE PATHOLOGY OF CUTANEOUS ERUPTIONS.

To the Editor of The Medical Press and Circular.

Sir,—I am glad to see that Dr. Walsh, and, I hope, many others, regard the study of cutaneous diseases in a very different way from that in which it was regarded some years ago. It was in 1865 that I listened to the lectures of Professor Hardi and Professor Behier, in Paris, and it seemed to me that the term, "dermatoses," in its limited special sense might be expanded into "dermatitis," as a term more useful to, and consistent with, English pathology. The simple fact that at a children's hospital 10 per cent. of the total cases came under the class of skin diseases was perhaps the chief reason that my attention was directed to the study of cutaneous disease. It seemed to me far more important to study the causes of these diseases than the minute variations presented in the character of eruptions; and that in the treatment of such cases it was far more necessary to study the constitutional causes of them than to deal with them in the very limited and unscientific method that seemed to have been followed up to that time. Why those who devoted themselves to skin diseases should have been regarded with contempt by the leaders of the profession is easily understood. Happily things are changing.

I am, Sir, yours truly,

Robert Lee.

THE TEACHING OF HYGIENE AND TEMPERANCE.

To the Editor of The Medical Press and Circular.

Sir,—I have no intention of raising any discussion on the merits of total abstinence, but with regard to the petition referred to in your annotation, I may be allowed to point out that considerable stress in various paragraphs is imposed on the word "temperance," and I think that it would be interesting to know the definition or meaning conveyed by the petitioners, as temperance and total abstinence nowadays appear so often to be used synonymously. Supposing however, the latter should be advocated in any of the schools, I would suggest the statistics in support thereof should be taught, duly qualified with regard to their uncertainty.

Some time ago I attempted in your columns to point out to asylum officials that the difficulty of determining how far drink played its part as a factor in determining any given case of drink as a cause of insanity was so complex as to be well nigh insuperable, and I may, by the way, refer to the painful and sensational case of suicide, which lately occurred to a much-respected lady doctor on the staff of a London hospital, whose habits were, according to the evidence, undoubtedly abstemious, if not of total abstinence. Now, sir, I venture to state that if this lady had been otherwise asylum statisticians would have tabulated the insanity due to excess of drink. On the other hand, I suggested that alcohol under some nervous conditions might tend to prevent insanity by helping to maintain the general health. So I submit, teachers cannot be too guarded in enunciating dogmas which, if viewed with a critical eye, may turn out to be erroneous.

I am, sir, yours truly,

Clement H. Sers.

Brighton, February 2nd, 1904.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list :—

Bailliere, Tindall & Cox (London).

Aids to Surgery. By Joseph Cumming, M.B., B.S., F.R.C.S. Pp. 394. Price 4s. 6d.

The Principles and Practice of Hydrotherapy. By Simon Baruch, M.D. Second Edition, revised and enlarged. Illustrated. Pp. 496. Price 16s. net.

A Pocket Dictionary of Hygiene. By C. T. Kingzett, F.I.C., and D. Homfray, B.Sc. Second Edition. Pp. 112. Price 2s. 6d.

A Method for the Treatment of the Apparently Drowned. By R. L. Bowles, M.D., F.R.C.P. Pp. 14. Price 6d. net.

Drugs: Their Production, Preparation, and Properties. By H. Wippell Gadd. Pp. 180 Price 3s. 6d. net.

Midwifery for Midwives. By W. Denison Wiggins, M.R.C.S. L.R.C.P., etc. Illustrated. Pp. 259. Price 3s. 6d. net.

Browne & Nolan, Ltd. (Dublin).

Transactions of the Royal Academy of Medicine in Ireland. Vol. 21. Edited by John B. Story, M.B., F.R.C.S., General Secretary. With Index, Vol. 1 to 20. Compiled by E. J. McWeeney, M.D.

Cassell & Co., Ltd. (London).

A Manual of Operative Surgery. By Sir Frederick Treves, Bart., K.C.V.O., C.B., F.R.C.S., &c. New Edition. Revised by the Author and Jonathan Hutchinson, jun., F.R.C.S. Illustrated. Two Vols. Pp. 1,574. Price 42s.

J. & A. Churchill (London).

Army Inefficiency: its Greatest Cause. By A. C. Profeit, M.B. Pp. 57. Price 1s. net.

Sulycitive Sensations of Sight and Sound By Sir Wm. R. Gowers, M.D., F.R.C.P., F.R.S. Pp. 250. Price 6s. net.

A Short Practice of Gynæcology. By Henry Jellett, B.A., M.D., &c. Second Edition, revised and enlarged. Illustrated. Pp. 406. Price 10s 6d.

Henry J. Glaisher (London).

Charles White, F.R.S., a Great Provincial Surgeon. An Address by Charles J Cullingworth, M.D., F.R.C.P., etc. With Notes and Illustrations. Pp. 56. Price 2s. 6d. net.

Charles Griffin & Co., Ltd. (London).

Milk: Its Production and Uses. By Edward F. Willoughby, M.D. Illustrated. Pp. 259. Price 6s. net.

H. K. Lewis (London).

The Sterilisation of Urethral Instruments. By Herbert S. Herring, M.B., B.S, &c. Illustrated. Pp. 176. Price 5s.

John Murray (London).

A Manual of General Pathology for Students. By Sidney Martin, M.D., F.R.S., F.R.C P. Illustrated. Pp. 502. Price 15s. net.

Young J. Pentland (London).

Manual of Surgery. By Alexis Thomson, M.D., F.R.C.S., and Alexander Miles, M.D., F.R.C.S. Vol. I. General Surgery. Illustrated. Pp. 763.

W. B. Saunders & Co. (London).

The Illustrated Medical Dictionary. By W. A. Newman Dorland, A.M., M.D. Third Edition, revised and enlarged. Pp. 798.

The Pocket Medical Dictionary. Edited by W. A. Newman Dorland, A.M., M.D. Fourth Edition, revised and enlarged. Pp. 566.

A Text-Book of Pathology. By Alfred Stengel, M.D. Fourth Edition. 21s. net.

A Text-Book of Diseases of Women. By Burton Cooke Hirst, M.D. Illustrated. Pp. 683. Price 21s. net.

A Text-Book of the Practice of Medicine. By James M. Anders, M.D. Sixth Edition, revised. Price 24s. net.

Nervous and Mental Diseases. By Church and Peterson. Fourth Edition, revised. Price 21s. net.

Modern Surgery. By J. Chalmers da Costa, M.D. Fourth Edition, enlarged. Price 21s. net.

The Four Epochs of Woman's Life. By Anna M. Galbraith, M.D. Second Edition, revised and enlarged. Price 6s. 6d. net.

A Text-Book of Surgery. By William W. Keen, M.D., and J. William White, M.D. Fourth Edition. Two Vols. Pp. 1,363. Price 30s. net.

The Treatment of Fractures. By C. L. Scudder, M.D. Fourth Edition, revised. Illustrated. Pp. 584. Price 21s. net.
A Manual of the Practice of Medicine. Prepared especially for students by A. A. Stevens, A.M., M.D. Sixth Edition, revised and enlarged. Illustrated. Pp. 556. Price 10s. 6d. net.
Atlas of the External Diseases of the Eye. By Prof. Dr. O. Haab. Second Edition, revised. Edited by G. E. de Schweinitz, A.M., M.D. Illustrated. Pp. 232. Price 18s. net.

SMITH ELDER & Co. (London).

The Management of Lateral Curvature of the Spine, Stooping, and the Development of the Chest in Phthisis. By E. Noble Smith. Pp. 138. Price 2s. 6d.
A Handbook of Ophthalmic Science and Practice. By Henry E. Juler, F.R.C.S. Illustrated. Third Edition, revised and enlarged. Pp. 733. Price 21s. net.

WILLIAMS and NORGATE (London).

Studies in Heterogenesis. By H. Charlton Bastian, M.A., M.D. Illustrated. Pp. 354. Price 31s. 6d.

JOHN WRIGHT & Co. (Bristol).

Eye Symptoms as Aids in Diagnosis. By Edward Magennis, M.D., D.P.H.
Golden Rules for Diseases of Infants and Children. By George Carpenter, M.D., M.R.C S. Second edition, enlarged. Pp. 167.

Obituary.

A MEDICAL MARTYR.

THE LATE DR. W. J. CONEYS, OF ROUNDSTONE.

IN our issue for January 27th, we gave a full account of the heroic devotion to duty and the untimely death of this practitioner. He had to visit one of those wretched hovels, in which escape from infection is almost impossible. His patient died, and, in his own words, "I could not get a man for love, whisky, or money to help me, and I was obliged to coffin the corpse along with the nurse and another." But the duty was heroically undertaken, and his life given for his patient. He in turn was devotedly nursed by Dr. Gorham, of Clifden, and when the end came and Dr. Coneys' servants and friends, fearing infection, would not approach the sick room, Dr. Gorham, with the assistance of the nurses, was obliged to himself place Dr. Coneys in his coffin. All honour to such heroism.

WILLIAM DONALD, M.D.ABERD.

WITH regret we announce the death of Dr. William Donald, at Aberdeen, on January 18th. For a year or more he had suffered from a painful internal malady, and some two months ago it was found necessary to have him removed to Aberdeen for the purpose of undergoing a surgical operation. This was successfully performed, and for a time it seemed as if recovery would ensue, but he ultimately died at the comparatively early age of 51. Dr. Donald was the eldest son of William Donald, M.D., Bogside of Eden, Aberdeenshire, and graduated at the University of Aberdeen as M.B. and C.M. in 1873. He passed the next few years in Banff, whence he went to Colombo, Ceylon, where he was district medical officer. Returning from Ceylon more than a quarter of a century ago, Dr. Donald settled in Banff and in time made for himself a large practice. He held various local appointments, among others those of visiting surgeon to the Chalmers Hospital, and certifying surgeon under the Factory Act.

DR. OWEN, M.D., M.R.C.S., L.S.A.

WE regret to announce a sad ending to a busy life on the last day of January, when Dr. Owen, M.D., M.R.C.S., L.S.A., was found partially dressed at the bottom of the staircase in the cottage in which he had resided of late years. His groans attracted a passer-by, who burst open the door, to find the doctor as stated above. Help was sent for, but before one of his colleagues could come he was dead. Dr. Owen, who qualified as far back as 1867, was at one time the medical officer of the whole of the Bromyard Union, which comprised thirty-two parishes, some of them a radius of sixteen miles apart, and this he did all on horseback.

MR. R. E. SMITH.

MR. R. E. SMITH, the village surgeon at Finchingfield, and medical officer to the Braintree Union, met with his death on February 3rd from the kick of a pony. On the previous day the doctor was shooting with a party at Spain's Hall, and the host (Mr. A. W. Ruggles-Brise) was riding a pony, from which he dismounted on coming to a hedge, and the animal ran through. Dr. Smith attempted to seize the bridle, but missed it, and as the pony passed him it kicked out, striking the doctor a severe blow in the face, rendering him temporarily blind and unconscious. He was at once attended by neighbouring medical men and by a specialist from Cambridge, but he succumbed to his injuries. Mr. Smith was medical officer of Finchingfield and look the L.R.C.S.I. in 1894.

Medical News.

150 Danish Soldiers Poisoned by Pork.

THE poisoning of no less than 150 soldiers is reported from the garrison of Aarhus, in Denmark. The cause of poisoning is probably due to the preparing of pickled pork in zinc pans which were insufficiently cleaned. All the soldiers to a greater or less degree are suffering from severe gastric intestinal irritation. The remaining pork has been sent for bacteriological examination.

London School of Medicine for Women.

THE annual meeting of the London (Royal Free Hospital) School of Medicine for Women was held last week. Mr. Holroyd Chaplin presided. The report presented by the council showed a favourable position as regarded the entry of students, and also as regarded their success in examinations. At the University of London two scholarships and two gold medals had been obtained by students of the school. In the matter of hospital appointments also the outlook was good. Several hospitals and infirmaries had for the first time appointed medical women to resident posts, and at the Lambeth Poor-law Schools a woman had been selected as medical officer from a large number of candidates. The financial position of the school, it was pointed out, was improved, but could never be wholly satisfactory until the debt of £5,000 on the buildings was cleared, and it was strongly urged that an effort

should be made to find some generous donors to help in this by larger or smaller contributions. Among those elected as members of the Association were Sir Victor and Lady Horsley, Lady Lockyer, and Professor and Mrs. Ayrton.

Recent Plague Scare.

In connection with the death of two Chinamen in the Seamen's Hospital, Greenwich, last month in circumstances giving rise to the suspicion of plague, the Public Health Committee of the London County Council reports that medical investigation shows that the men died of influenza. Two other cases of syspicious sickness in Limehouse were also investigated by Mr. Cantlie, who was satisfied from the clinical symptoms that there was no question of plague in either instance.

The German Birth-Rate.

The steady decrease in the number of births in Germany during the last few decades is a marked and unsatisfactory feature of the social and economic conditions of the empire. From 1870 to 1880, the number of births was 40 for every thousand inhabitants; during the following decade it fell to 38·2 per 1,000; and from 1890 to 1900 it was not more than 37·4 per 1,000 or about as much as during the Fifties. This decrease, however, has hitherto been compensated by the decrease in mortality. From 1890 to 1900, for instance, the death-rate decreased by more than two per 1,000. In Berlin the decrease in the birth-rate has been especially marked, the total number of births in the capital being 1,700 less in 1903 than two years ago. The actual number of births in Berlin was 49,000 in 1903, 52,259 in 1901.—*Standard*.

Four Patients Poisoned at a Lunatic Asylum.

Four female patients have been accidentally poisoned at Portsmouth Lunatic Asylum. It has been the custom at that institution to administer soothing draughts to violent patients when there is a danger that they will get beyond control. On Wednesday evening a draught composed of bromide of potash and chloral was administered to four female patients by the orders of Miss Watson, the lady doctor. Two hours later they were all four taken ill, and, in spite of the unremitting efforts of the medical staff and nurses, two of the women died that night and the other two on Thursday. The cause is supposed to be an overdose of chloral. Similar draughts had been administered on former occasions with satisfactory results, and it is stated that the doses given to the four women were not larger than usual.

Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society took place on the 29th ult., at 429 Strand, W.C. The accounts presented show that the society's business is in a very healthy state, and the report for 1903 to be presented to the members in May next will be found very satisfactory. Prospectuses and all particulars of Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

Sewage-polluted Shell Fish.

In his report on the public health of the City, Dr. Collingridge, the medical officer of health, alludes to the recent report of the Royal Commission on Sewage Treatment and Disposal on the Contamination of Shell Fish, and cordially approves of the proposed remedial measures. He, however, considers that the authority for the Thames should be the Corporation as Port Sanitary Authority so far as its jurisdiction over the river extends. Dr. Collingridge proceeds to refer to a discovery of sewage-polluted mussels from South Holland. The dealers in Billingsgate had sold the mussels in accordance with instructions received from the Fishmongers' Company, namely, to caution purchasers to boil them for three and a half or four minutes, and they had exhibited a notice to that effect. That was a most unsatisfactory mode of dealing with the matter. The mussels were known to be sewage contaminated, and therefore dangerous to health, and in no circumstances could there be any sufficient guarantee that the recommendation would be properly carried out. As mussels were largely imported from Holland at this season, the facts were brought to the knowledge of the Board of Agriculture and Fisheries, the Local Government Board, the Netherlands Government, and the Fishmongers' Company. Since then three cases of enteric fever arising from mussels purchased in the City had been reported. In these instances the mussels came from Hadleigh, Essex. The proprietors of the layings had given an undertaking to sell no more Hadleigh mussels until they were declared free from contamination. The Fishmongers' Company and the Netherlands Government were co-operating with a view to having a thorough investigation made of the conditions under which mussels were cultivated and exported to this country.

Ventilation on Scientific Principles.

The "Boyle" system of ventilation having been successfully applied to the Spanish Cortes, Madrid, it is now to be carried out, by direction of the French Government, for the ventilation of the Musée du Louvre, Paris. It is also proposed to apply the same system to the Chamber of Deputies, the mechanical appliances tried in that building, including the "Plenum," having proved failures.

Lead in Cream of Tartar.

At West Ham, Messrs. Leverett and Frye, Limited, grocers, were summoned for selling cream of tartar which was not of the nature, substance, and quality demanded. On December 22nd, one of Dr. Sanders' assistants bought a quarter of a pound of cream of tartar for 4d. at the defendants' shop. Dr. Dyer (analyst) said that the sample he analysed contained lead in the proportion of rather more than one grain to the pound. The effect would be to render it injurious to the health of anyone who consumed it. Mr. Beck, for the defence, said that no one suggested that the defendants were responsible for this lead in the cream of tartar. Its presence was to be accounted for solely by reason of the mode of manufacture, and the defendants were merely the victims of the foreign manufacturers. Mr. Gillespie: You suggest you were justified in selling it with this lead in? Mr. Beck: Without any knowledge that we were selling an article containing lead. What my friend is putting up is the standard of the 1898 *British Pharmacopœia*. Mr. Beck added that in the new *Pharmacopœia* cream of tartar was referred to as "purified cream of tartar." Mr. Gillespie said he did not suppose for a moment that the defendants wilfully put lead into this cream of tartar, but on the evidence it was shown that its presence could be discovered with ordinary precautions. He imposed a fine of £10, including costs.

International Congress of Dermatology.

The fifth International Congress of Dermatology will be held at Berlin from September 12th to 17th, 1904, Professor E. Lesser being President. The following questions will be discussed: (1) Skin affections in anomalies of metabolism; (2) syphilitic diseases of the circulatory organs; (3) epithelioma and its treatment; (4) (*a*) the state of matters as to the distribution of leprosy and its repression since the Leprosy Conference of 1897; (*b*) the present state of knowledge as to anæsthetic leprosy. All communications should be addressed to the General Secretary, Sanatatsrät Dr. O. Rosenthal, Potsdammerstrasse 121 g, Berlin.

Trinity College, Dublin.

At the examinations during Hilary Term, 1904, the following candidates passed:—

Final in Midwifery.—Charles J. Coppinger, Keith R. C. Hallowes, Richard C. Hallowes, Henry M. Crawford, William M. Wade, Rev. Richard B. Bryan, Cecil J. Wyatt, David C. Pearson, Owen J. Parry-Edwards, Maurice FitzGibbon, Harold T. Marrable, Thomas Wilson, Hugh Stewart. *Section B*.—John Cunningham, Robert Magill, John A. Sibthorpe, James H. C. Thompson, Wilfred L. Myles.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

THE HUMAN HYMEN.

This structure which anatomists term the hymen has proved an almost insoluble problem to biologists, and in human affairs has exercised an influence over religious ritual, legal rights and social procedure which cannot well be estimated, and is impossible to express adequately. Metchnikoff, in his remarkable work on "The Nature of Man," in the study of disharmonies of reproduction points out that the hymen, the physical indication of virginity, is peculiar to the human race. It is absent in the anthropoid apes, and even in the development of the female fœtus this structure appears late, evidently indicating that it is a comparatively late acquirement. No one has satisfactorily explained its utility. It has, of course, played an important part in judicial procedure, and much moral significance has been given to it, but as far as can be ascertained it is of no functional value. In certain countries it is regularly destroyed as part of the toilet of young children. It is of no distinct service in the sexual progress, and may even prove a bar to marital duties. It is remarkable that a structure which has no great ancestral heritage, is functionless and non-essential to sexual union, should persist in spite of its almost unavoidable rupture in the process of childbirth. It, however, affords a powerful argument against the transmission of acquired characters.

EDINBURGH.—A short paper on "The Treatment of Phlegmasia Alba Dolens" reached us a few weeks since with the Edinburgh postmark on envelope, but no name attached to the article. We shall be glad if the writer will kindly communicate with us.

DR. H. R. S.—The supposition is a common one, but the similarity exists in name only.

AN ANXIOUS ONE.—The instrument to which you refer is an American invention styled "The Massacon," the object of which is to break down or reduce the thickening around the ossicles in middle ear deafness by electro-massage. The instrument was introduced to the profession in this country at the Manchester Congress of the British Medical Association in 1902, and we believe success has attended its use in certain cases, but we know nothing of it from personal experience.

H. P. P.—Try radium without a moment's loss of time—the malignant growth you describe is within easy reach. It is necessary, however, to make sure that your radium is of the best quality.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 10th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8 p.m. Annual Meeting. 8.30 p.m. Dr. J. F. Woods: The Psychic Side of Therapeutics. (Hunterian Oration.)

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common).—8.45 p.m. Sir Felix Semon: Some Desultory Remarks on Topics of Professional Interest.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. R. Harrison: Clinique. (Surgical.) 5.15 p.m. Mr. J. Poland: The Treatment of Congenital Club-foot.

THURSDAY, FEBRUARY 11th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Papers:—Mr. E. Owen: Appendix Abcess in the Recto-vesical Pouch.—Mr. E. W. Boughton: A Case of Intestinal Obstruction with Gangrene of the Cæcum, Recovery.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. The President (Prof. J. Taylor): Inaugural Address. Papers will be read and specimens shown by Dr. G. Atkins, Dr. W. Duncan, Dr. Macnaughton-Jones, Dr. Snow, and Mr. Spanton.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, Cavendish Square, W.).—8 p.m. Cases will be shown by Mr. A. Ogilvy, Mr. S. Stephenson, and others. 8.30 p.m. Papers:—Dr. A. Brown: Notes on a Case of Gonorrhœal Conjunctivitis in an Adult Treated with Peroxide of Hydrogen.—Mr. J. H. Parsons: On Congenital Anterior Staphyloma.—Major H. Smith, I.M.S.: (1) Light-blindness: (2) Lens Couching.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. G. Brodie: The Pathology of Uræmia.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy Square, W.).—5 p.m. Dr. F. P. Weber: The Relations of Pulmonary Tuberculosis to other Diseases. (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6.15 p.m. Dr. M. Dockrell: Fungus Diseases of Hair. (Chesterfield Lecture.)

FRIDAY, FEBRUARY 12th.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, Strand, W.C.).—7.30 p.m. Dr. L. Stephens: Physical Culture in Elementary Schools.

HUNTERIAN SOCIETY.—7 p.m. Annual Dinner.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Dr. S. Phillips: A Case of Fibroid Disease of the Pancreas with Calculi, accompanied by Jaundice and subsequently by Diabetes. Laparotomy, Relief of Symptoms, Death.—Dr. N. Dalton: Two Cases of Malignant Anæmia due apparently to Defective Formation of the Red Blood-corpuscles and Associated with Caries of the Teeth and Suppuration of the Lower Jaw.—Mr. J. J. Clarke: Notes on a Case of Ankylosis of both Temporo-maxillary Joints.—Mr. E. M. Corner: Cases of Primary and Secondary Tuberculosis of the Thyroid.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. S. Stephenson: Clinique. (Eye.)

Vacancies.

Barnwood House Hospital for Mental Diseases, Gloucester.—Junior Assistant Medical Officer, Salary £150 a year, with board, &c. Applications to the Medical Superintendent.

Birkenhead Union.—Resident Assistant Medical Officer, Salary £120 per annum, with board, washing, and apartments. Applications to John Carter, Clerk to the Guardians, Union Clerk's Offices, Birkenhead.

Camberwell House Asylum.—Second Assistant Medical Officer, Salary £150 per annum, with board, residence, and laundry. Applications to Medical Superintendent, 33, Peckham Road, London, S.E.

Carmarthenshire Infirmary.—Resident Medical Officer, Salary £100 per annum, with furnished apartments, board, attendence, fire, gas, and washing. Applications to Howell Howell, Secretary.

City of Sheffield.—Second Assistant Medical Officer, Salary £150 per annum, with board, lodging, and attendance. Applications to H. Sayer, Town Clerk, Town Clerk's Office, Town Hall, Sheffield.

Joint Counties Asylum, Carmarthen.—Junior Assistant Medical Officer, Salary £150 per annum, with board, furnished apartments, and washing. Applications to Dr. Goodall, Medical Superintendent, The Asylum, Carmarthen.

Kettering and District General Hospital.—Resident Medical Officer, Salary £80 per annum, with board, residence, &c. Applications to H. T. Berry, Hon. Sec., 3, High Street, Kettering.

Macclesfield General Infirmary.—Junior House Surgeon, Salary £70 per annum, with board and residence at the Institution. Applications to the Chairman of the House Committee.

Royal Albert Edward Infirmary and Dispensary, Wigan.—Junior House Surgeon, Salary £80 per annum, with board, apartments, and washing. Applications to W. M. Taberner, General Superintendent and Secretary.

The Guest Hospital, Dudley.—Senior Resident Medical Officer, Salary £100 per annum, with board, residence, attendance, and washing. Applications to the Secretary.

The Royal Waterloo Hospital for Children and Women, Waterloo Bridge Road, S.E.—Head Dispenser. Applications to the Secretary. (See Advt.).

Worcester General Infirmary.—House Surgeon, Salary £70 per annum, with board and residence. Applications to William Stallard, Secretary, Worcester Chambers, Pierpont Street, Worcester.

Appointments.

BERESFORD, R. DE LA POER, M.D.Glasg., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Oswestry.

CORNER, EDRED M., M.B., B.S Cantab., F.R.C.S.Eng., Assistant Surgeon to St. Thomas's Hospital.

FRY, W. W. B., M.B., C.M.Edin., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Builth Wells.

HUMPHREYS, C. E., M.R.C.S., L.S.A., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Llanfair.

JONES, F. F., M.R.C.S., L.S.A., D.P.H., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Llanfyllin.

KENWOOD, H. R., M.B., C.M.Edin., D.P.H., Professor of Hygiene and Public Health at University College, London.

MURRAY, J., M.B., C.M.Glasg., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Llandrindod.

PROCTOR, THOMAS, M.R.C.S., L.R.C.P.Edin., Medical Officer and Public Vaccinator for the Fifth District of the Chipping Sodbury Union.

RICHARDSON, F. L. C., L.R.C.P. and S.Edin., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at Rhayader.

SALTER, F. W., L.R.C.P. and S.Edin., Medical Examiner of Recruits for the Montgomery Imperial Yeomanry at New Mills.

SMITH, WILLIAM ROBERT, M.D., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Hospital for Women, Nottingham.

Births.

DAWSON.—On February 4th, at 32, Wimpole Street, W., the wife of Bertrand Dawson, M.D., F.R.C.P., of a daughter.

SMITH.—On February 5th, at Waldon House, Watford, the wife of G. Francis Smith, M.R.C.S.Eng., L.R.C.P.Lond., of a daughter.

Deaths.

CHEESE.—On February 7th, at Woodville House, Amersham, Mary Jane, wife of John Cheese, and only child of Wm. Macmichael, M.D., F.R.S., F.R.C.P., Physician in Ordinary to His Majesty King William IV., and Principal Librarian to her late Majesty Queen Victoria.

Original Communications.

THE APPLICABILITY OF RADIUM IN THE TREATMENT OF A CANCEROUS THROAT.

By DAVID WALSH, M.D.,

Senior Physician, Western Skin Hospital, London, W.; late Honorary Secretary, Röntgen Society of London, &c.

THE possibilities opened up in the treatment of cancerous growths by the discovery and introduction of radium are full of brilliant promise. For the moment, however, the results of patient investigation must be awaited before it is possible to speak with certainty as to the exact therapeutic value of this wonderful substance. At the same time it may confidently be asserted that we have in radium an agent whereby it is possible to modify profoundly, and in some cases apparently to cure, surface rodent ulcers and epitheliomata.

Encouraging reports of the treatment of malignant disease by radium have come from America, notably from Dr. Morton, of New York. In Vienna it has been somewhat extensively used for the same purpose. Exner and Holzknecht (*a*) have used it in cases of carcinoma and sarcoma, "with results that are so far satisfactory." An account of their cases was read before the Medical Society of Vienna on June 26th, 1903. The first case was that of a man, æt. 37, who had undergone an operation for melano-sarcoma of the humerus three years previously. For eight months he suffered from small subcutaneous, dark-coloured nodules near the seat of operation. Microscopically, a nodule was found to be of a melano-sarcomatous nature. Radium was applied to these small metastatic nodules, which varied in size from $\frac{1}{8}$ to $\frac{3}{8}$ of an inch in diameter. The method of application was to enclose the radium in a small india-rubber capsule with a mica window. The capsule was then fixed to the skin by means of a strip of adhesive plaster, exactly over the nodule, with which it was kept in contact from a quarter of an hour up to twenty-five minutes. In from two to forty-eight hours a dermatitis followed, resembling the X-ray or focus-tube dermatitis. Where the application had lasted less than fifteen minutes no change was found in the nodule at the end of a fortnight. On the other hand, in those nodules which had been treated for a quarter of an hour or more (up to twenty-five minutes) there was either a marked diminution or disappearance of the nodules. New nodules developed on the shoulders, breast, and left upper arm, but disappeared beneath the influence of the radium, their former site being marked by a flat depressed cicatrix.

The second case was that of a man, æt. 61, who was operated on for an epithelioma of the cheek in 1888, and for recurrences in 1891 and 1897. On May 11th, 1903, he was found to have an ulcer the size of a shilling at the right corner of the mouth, while a hard tumour the size of a small hazel-nut could be felt in the surrounding tissue. Six exposures to radium, each one lasting from fifteen to twenty-five minutes, were followed by shrinking of the tumour and healing of the ulcer, so that both had disappeared by June 26th. The patient, however, died of recurrence within a few months.

In a third case an epithelioma of the cheek, the size of a sixpenny piece, healed after three applications of radium. This patient passed out of observation.

In the United Kingdom brilliant results have been obtained by Mr. Mackenzie Davidson, M.B., the well-known inventor of an exact system of X-ray localisation. A brief note on the subject has been recently published by him. (*a*) His first case was one of rodent ulcer on the right side of the nose in a woman, æt. 69. The ulcer, which measured 1 by $\frac{3}{4}$ inch, had resisted treatment, both by the Finsen light and by the X-rays. Treatment by radium began on May 21st, and on June 11th, after four applications, "the ulcer was practically healed." Five months later there had been no recurrence.

The most important of Mr. Davidson's cases was an extensive rodent ulcer of the right side of the face. It would be more correct, apparently, to describe the condition as cancerous, inasmuch as the surgeons who saw the patient in the early stages stated that it was an undoubted case of epithelioma. When first seen, the whole of the cheek had been destroyed and the tongue and teeth were laid bare; the upper and lower lips were destroyed to within an inch of the middle line; the tongue was foul, and there was an offensive discharge from the whole of the ulcerated surface; the hard and the soft palates were invaded and the patient could not speak. Treatment began on July 30th, and continued for some months. The patient can now speak, the tongue is clean, the discharge inoffensive, and cicatrisation is going on steadily. The disease, according to Mr. Davidson, "has been arrested," and a complete cure may reasonably be expected. Full

(*a*) *Brit. Med. Journ.*, December 26th, 1903.

(*a*) *Brit. Med. Journ.*, January 23rd, 1904.

details of this important case will be published later.

Meanwhile, it is clearly a matter of general interest to know the methods of application and the limitations of radium. The radium is most conveniently used in the form of the bromide, and should be of good quality. The small glass tube containing the salt must be placed directly in contact with the ulcerating surface. It apparently is of no use if applied to the unbroken skin surface overlying, say, a scirrhus of the mamma. The action of the radium is strongest at the immediate point of contact, and lessens in power according to the distance from that point of contact. The radium may be applied for a quarter of an hour or more, up to thirty or forty minutes, but the length of application should be most carefully regulated by individual results. A reaction occurs usually on the eighth day of treatment. If it be moderate the temperature runs up to about 100° F., and the patient suffers little general disturbance. On the other hand, if the exposure has been unduly prolonged, the temperature may run up to 104° F. or even higher, and the patient be attacked by vomiting and other distressing symptoms. In one of Mr. Davidson's cases the ulcerating surface became scarlet and erysipelatous-looking during a period of severe reaction, but immediately afterwards underwent a marked local improvement. The suggestion of Mr. Davidson that the reaction may be due to the formation of an antitoxin is of great interest.

It will be at once apparent that the necessity of direct application of the radium to the tissues involved in the malignant process must for the present limit the field of applicability of radium. Still, much may be achieved by the exercise of a little patience and ingenuity on the part of the operator. Thus, a Continental surgeon (*a*) has treated malignant stricture of the œsophagus by passing bougies armed at the end with a bulb so constructed and placed as to bring the radium in contact with the stricture. In the case of an epithelioma inside the cheek there would obviously be little difficulty in maintaining contact of the radium tubes with the diseased surface for any required length of time. It is far otherwise, however, when one has to deal with a malignant invasion of the palate and fauces, when the structures are in a state of constant watchfulness to respond to and resent reflexly almost all kinds of direct stimulation. To keep one or more small glass tubes in contact with various parts of the reflexly sensitive and excitable soft palate and fauces might seem *a priori* to be an almost hopeless task. The object of this short preliminary communication is to show that it is quite feasible to treat the oropharyngeal region by the direct application of radium.

A patient came under my care suffering from early but rapid malignant invasion of the upper throat. At first I tried the application of the high frequency current of the X-ray tube, the latter especially to the glands at the angle of the left jaw, which were slightly enlarged and tender. At the same time I devised an apparatus whereby the rays from the focus-tube could be projected directly on to the back of the throat by means of a flattened vulcanite speculum. Some improvement followed this course of treatment, but not long after its commencement I made some inquiries as to radium and determined to try that agent.

By the kindness of Mr. Mackenzie Davidson I was enabled to carry out the treatment under his supervision. He most kindly and generously placed at my disposal four sealed tubes, each containing five milligrammes of pure radium bromide. These tubes were fastened at the end of a curved holder and enclosed in a covering of india-rubber extemporised from a finger stall. The throat was then cocainised and a gag inserted between the teeth. A light thrown into the mouth by a mirror enabled me to pass in the radium and press it with precision on the desired part. At first the patient showed the greatest intolerance of contact with the foreign body, but by dint of perseverance it was found possible to push the application sufficiently to give from a quarter of an hour to half an hour, or sometimes forty minutes, distributed on various parts of the palate, fauces and pharynx. As a matter of fact, the patient sometimes could not bear the contact for more than a few seconds, while at other times he could tolerate the pressure for one minute, two, and occasionally three or four minutes together. In estimating the time of application allowance had to be made for the continual stoppages, while the radium holder, and in many instances the gag also, were removed from the mouth. Anyone acquainted with throat work will realise that to stoop over a patient and hold an instrument in position under these circumstances demanded a good deal of patience, especially when the fœtor of a malignant throat is taken into consideration.

The parts involved were the left tonsil, which presented a sloughing surface, and the neighbouring pillars of the fauces, part of the posterior pharyngeal wall, the whole soft palate on the left side, which showed a deep sloughing pond-like depression, that would about receive the tip of an average-sized middle finger. The left palate was paralysed, so that the uvula was drawn over to the right by the action of the unaffected muscle of that side. The uvula was partly destroyed. The process had superficially attacked the right soft palate.

The appearance of the lesion was suggestive of other specific mischief, but that view was negatived —(*a*) by the history ; (*b*) by the opinion of various distinguished authorities on the throat ; (*c*) by two microscopical examinations, the report from which was detailed and emphatic.

The case is of importance inasmuch as it appears to be the first in which radium has been applied to a cancerous throat. It would be premature to give in this place an account of the results of this particular line of treatment. At the same time one may be perhaps allowed to say that the ordinary progress of that terrible condition, epithelioma of the upper throat and fauces, has been profoundly modified, if not, as one hopes, even arrested. Meanwhile, I have thought it my duty to lose no time in publishing the fact that it is possible to apply radium to the soft palate, the tonsils and the posterior pharynx. Henceforth, medical men who have cases of malignant disease of the upper throat and fauces will know that it is possible to apply radium to the seat of the disease. Further, in fairly early cases there appears to be a prospect of cure.

Since the above was written a patient has come under my care with an epithelioma of the tongue. He had been for several months abroad under-

(*a*) A fuller reference cannot be given here, as the report has been published only in the lay Press in this country, and awaits scientific confirmation.

going Dr. Otto Schmidt's method, based on his alleged cultivation of a parasite of cancer. By inoculations of increasing virulence of serum or of sterilised cultures it is hoped to obtain immunisation against cancer. In the case of my patient, in spite of several months of careful treatment by Dr. Schmidt, both the original growth and the glands of the neck showed a steady increase in size. He has now placed himself in my hands for energetic treatment by radium and high frequency current applied to the tongue, and by X-ray and high frequency to the enlarged glands.

A CASE OF AN APPENDIX ABSCESS IN THE RECTO-VESICAL POUCH. (a)

By EDMUND OWEN, F.R.C.S.,
Consulting Surgeon to St. Mary's Hospital.

A GENTLEMAN, æt. 45, was sent to me on August 17th last with a history of intermittent trouble with defæcation, and of a feeling of fulness and weight about the neck of the bladder. His doctor wrote that last May the patient had been treated for obscure abdominal pains which were centred in the hypogastric region. At that time no rectal examination had been made, but when the practitioner had recently introduced his finger into the bowel, he had found a tumour which felt like an enormously enlarged prostate gland. For several years the patient had had obscure abdominal pains, and he had become dyspeptic to such an extent that he was afraid to eat meat. Three months previously he had had severe pains in the hypogastric region, for which he was kept in bed. He told the doctor who was attending him that he thought he must have got appendicitis, so great was his distress. But the doctor, finding that there was neither swelling nor tenderness in the right iliac fossa, put it down to the after-effects of influenza, and applied fomentations over the hypogastric region. When the acute attack passed off, the patient was able to resume work, but he was very miserable and depressed, and was steadily losing weight.

The finger introduced into the bowel at once came upon a hard, tender swelling at the base of the bladder. It was about the size of a small hen's egg. It was not prostatic, but it was close to the prostate gland, and intimately attached to it.

On opening the abdomen in the middle line and working cautiously among coils of closely-adherent intestine, I found at the very bottom of the recto-vesical pouch a tightly-filled abscess, the walls of which were composed of the rectum behind, the prostate below, and the bladder in front, whilst a kinked piece of the colon formed its roof. To the right side of the abscess, and firmly glued to the base of the bladder, was the end of the appendix, inflamed and ulcerated.

Having removed the appendix, and having thoroughly wiped out the abscess-cavity with dry swabs of absorbent wool, I passed a very large drainage-tube down into the recto-vesical pouch and brought the other end out a little below the umbilicus.

Though the peritoneum showed itself proof against infection by the bacillus coli, the surface-wound became infected about a fortnight after the operation, and so severe was the attack of cellulitis caused thereby that some large branches of artery in the epigastric region burst out bleeding on two occasions, and the patient was near dying from secondary hæmorrhage. As it is, however, he completely recovered.

My explanation of the case is that, some indefinite time ago, he had probably had a mild attack of inflammation, which fixed the tip of a long and wandering appendix in the depths of the pelvis, and that a few months ago there was recrudescence of the inflammation with severe hypogastric pains, and with the formation of the abscess.

Had he been operated on just after his first attack (whenever that was) he would have avoided the grave risks which were inseparable from the more serious operation. The appendix was not in the pelvis originally; it was probably dragged there by the adhesions which formed about it at the time of its first inflammatory attack, and if it had been resected as soon as that attack had passed off there would have been no intra-pelvic abscess.

The more that I see of appendicular disease, of the danger of delay in operating, of the comparatively slight amount of risk which the early operation involves, and of the great sense of relief and freedom from anxiety which it affords, the more fully am I convinced that the patient had best take his courage in both hands and submit to a prompt resection after a first attack.

(a) Abstract of a Paper read at a meeting of the Harveian Society of London, February 11th, 1904.

GLAUCOMA AND THE GLAUCOMA THEORIES. (a)

By J. V. PATERSON, F.R.C.S.,Edin.

DEALING first with the normal intra-ocular tension and the escape of fluid from the eye, it was pointed out that the aqueous humour was secreted by the epithelium in the ciliary region, and was eliminated by the so-called "filtration angle" (between the iris and cornea) and to a less extent by the vessels of the iris. An outline of the experimental work done in investigating the question of the exact channels of outflow was given, and a number of slides of sections of human and animal eyes demonstrated, the latter to show the channels by which Chinese ink was eliminated after injection into the vitreous. As to the rate of flow through the eye, Leber's estimate that the fluid in the anterior chamber was renewed every forty minutes seemed rather too high than too low; there was no appearance of current in the anterior chamber, so that the outflow must be very gradual indeed. The intra-ocular pressure is intermediate between the arterio-capillary and venous pressures —probably about 25 mm. Hg. It is subject to very slight variation at different periods and is not, as Hess has shown, affected by accommodation. It can never, of course, exceed that of the arteries supplying the eyeball. In the living eye nothing was easier than to see how pressure with the finger first caused collapse of the veins, then venous pulsation, and finally arterial pulsation—the latter being a characteristic of glaucoma. To some extent the intra-ocular tension

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, February 3rd, 1904.

ran parallel to the blood pressure—a fact which had been demonstrated experimentally on animals. Turning to glaucoma, which was defined as a state of increased intra-ocular tension, the speaker said he did not propose to discuss the clinical features of the condition. Part of our lack of knowledge of its pathology was due to the fact that attempts to produce it artificially in animals had met with little success. The condition might be either primary, or secondary to other diseases of the eye. A number of slides illustrating sections of eyes affected with secondary glaucoma were shown, and the mechanism by which the lesions had caused glaucoma was explained. In primary glaucoma, however, none of these simple mechanical explanations were adequate. A great obstacle to the elucidation of the pathology of the disease was the fact that eyes were not enucleated at an early stage, but only when secondary changes had set in. The morbid appearance of ordinary glaucomatous eyes at the stage at which enucleation was performed was now perfectly well known, but it was quite impossible to say which of these changes was the primary cause of the disease. For this reason, until by some fortunate chance a glaucomatous eye was got at its earliest stage, it was doubtful whether histology could throw any further light on the condition. Slides illustrating the changes in glaucoma were then shown, and the speaker proceeded shortly to discuss the various theories of glaucoma. Von Graefe and Donders thought it was due to hypersecretion, but this view is now generally abandoned. Knies had ascribed the condition to a blocking of the filtration angle by an adhesive inflammation of the tissues in that region, while Weber thought that a similar blockage took place in consequence of swelling of the ciliary body. While the lesion described by Knies was of the greatest importance, it could only be regarded as secondary, since it was absent in early cases of acute glaucoma. Priestley Smith supposed that, especially in hypermetropic eyes, the circumlental space became narrowed by the growth of the lens; that any swelling of the ciliary processes might completely obliterate it and prevent the flow of fluid forwards, and that in consequence the root of the iris would be pressed forwards and occlude the filtration angle. There was not, however, any direct evidence of the correctness of this hypothesis. The theories of Panas, Abadie, and others were passed in review, and shown to be untenable or inadequate. The speaker laid stress on the frequency with which chronic glaucoma was associated with general vascular changes, and thought that while undoubtedly some forms of eye (hypermetropic) were predisposed to glaucoma, while others (myopic) were not, a careful examination of the circulatory system by modern instruments for investigating blood pressure might throw light on the pathology of the disease. As he had already said, little more was to be gained from examinations of old glaucomatous eyes, nor from experiments on animals, but if, as he was informed, it should prove to be the case that domestic pets, kept under highly artifical conditions—*e.g.*, pampered lap-dogs—were occasionally the subjects of glaucoma, it might at some time be possible to get an eye in the early stage from this source.

A STRATFORD chemist has been fined £5 under the Food and Drugs Act for selling cream of tartar containing there-quarters of a grain of lead to the pound.

SOME RECENT OPERATIONS PERFORMED IN THE ROTUNDA HOSPITAL.

By E. H. TWEEDY, F.R.C.P.I.,
Master of the Rotunda Hospital, Dublin.

THE following cases which have recently been under my care in the gynæcological department of the Rotunda Hospital are of considerable interest:—

Case I.—Mrs. B—— was admitted suffering from acute pyosalpinx of the left tube. On the right was felt a hard mass of cicatricial tissue, the remains of a former pyosalpinx, for the cure of which an abdominal section had been performed two years ago. On that occasion the operation was much impeded by dense adhesions which prevented the disease being removed, and necessitated the mere drainage of the abscess through the vagina.

Her convalescence was prolonged and gave cause for much anxiety, and this history warned me against attempting a similar procedure.

I performed a posterior colpotomy instead, and burst into the tube by a finger inserted through the incision: washing out, curetting, and plugging the cavity completed the very simple operation, and the patient left the hospital with a normal temperature and cured of all subjective symptoms of disease within a fortnight.

I desire to strongly urge the propriety of this treatment in all cases of acute pyosalpinx; the cure of the disease follows it in a fair proportion of cases, and should the subsequent microscopic examination prove the disease to be tuberculous in origin or in the event of recurrence, Landau's very radical, rapid and safe operation can be subsequently undertaken.

Case II.—This is of interest to me as being the first in which I have performed the operation of symphysiotomy.

Mrs. M——, a delicate, nervous primipara, was admitted on January 22nd, in the early stages of labour; the fœtal head was freely ballotting above the brim, the conjugate vera measured four inches. In spite, however, of the slight degree of flattening of the pelvis I had no doubt that serious difficulty would be experienced in her delivery. I was led to this conclusion by adopting the device recently so cleverly described by Dr. Munroe Kerr, of Glasgow, and noting by its means the serious disproportion which existed between the fœtal head and the pelvis.

At the end of thirty-six hours the membranes ruptured during a vaginal examination, and the os was fully dilated. In six hours after this her pulse had risen to over 110, the lower uterine segment was greatly stretched, and in spite of a large caput having formed on the fœtal head, it had not moulded into the pelvis. Forceps was now applied, but failed in its object, though it was withdrawn and applied at different diameters of the skull.

The fœtal heart being still distinctly heard, there seemed no alternative open to me but to perform symphysiotomy. Accordingly, the patient was wheeled into the theatre still under an anæsthetic, and the symphysis was divided with comparatively little difficulty, and no complications. The child was easily extracted by forceps, but unfor-

tunately was born dead. The patient has made an excellent recovery, which would have been uneventful save for a slight attack of cystitis.

Case III.—M. T——, who had been operated on two years previously for an ovarian cyst, was admitted suffering from a tumour in the old scar. On this being excised and submitted to our pathologist, Dr. Neville, he reported that it consists of implantation tissue, the product of the tumour previously removed.

Case IV.—Mrs. R——, æt. 31, a collier's wife, was admitted with a history of deep laceration of the cervix; her last confinement had occurred three months before admission, and there was nothing to lead me to suspect from her appearance and from that of the lacerations that the case was one of malignancy. The suspicions of my assistants and myself were first aroused to the true nature of the case by the difficulty experienced in preventing the stitches which were applied from cutting through. A small piece of tissue was removed for microscopic examination, and Dr. Neville having pronounced it malignant, a vaginal hysterectomy was performed next day.

The disease having involved the vagina it became necessary to remove this structure very freely. This ringing of the vagina complicated the operation to no little extent, and the bladder was incised during the subsequent steps of the operation. Clamps were applied to the broad ligament, and the transverse incision of the bladder was brought together by catgut ligatures.

The patient's convalescence gave cause for great anxiety, as practically no urine was voided for the first forty-eight hours after operation. It was difficult to determine whether this was a case of suppression, or the result of occlusion of the ureters by the catgut sutures. At the end of fifty hours, quantities of blood-tinged urine came away, and this, taken in conjunction with the insatiable thirst experienced, the dull aching over the loin, and the absence of any pelvic pain inclines me to the belief that suppression and not mere retention was the cause of her trouble. The patient is still in hospital, suffering from a vesical fistula, which I intend to operate on when the ulcerated vagina resulting from the pressure of the clamps has been cured.

Case V.—J. W——, a nervous unmarried woman, æt. 43, was admitted suffering from severe hæmorrhage, the result of two myomata, the size of pigeons' eggs, situate one on the anterior, and the other on the posterior wall of the uterus. In this case I performed both anterior and posterior colpotomy, removing the tumours by a myomectomy, and leaving the uterus intact. Two gauze drains were inserted for twenty-four hours and the patient's recovery has been uneventful.

Case VI.—Mrs. ——, admitted suffering from pyosalpinx on the right side; the tube was greatly elongated, distended to the diameter of one's thumb, but was only slightly adherent to surrounding structures. It was easily removed by a posterior colpotomy and the subsequent history of the patient was uneventful.

Case VII.—Miss Y—— was admitted to the Rotunda Hospital suffering from painful tumours at either side of the uterus, of solid consistency and so closely connected with that organ that a diagnosis of multiple myomata was made by myself and my two assistants.

On opening the abdomen one of the tumours came into view, and was pierced by a corkscrew without the escape of any fluid resulting. On being pulled out through the wound it was seen to consist of solid ovarian tumour which Dr. Neville reports as being a very remarkable example of cancer.

On the other side the tumour proved to be a dermoid of the ovary. The patient is making a normal recovery, but I am much exercised in my mind as to the propriety of performing another operation for the removal of the uterus and broad ligaments.

PROGNOSIS IN HEART DISEASE. (*a*)

By JAMES BARR, M.D., F.R.C.P.,

President, Liverpool Medical Institution; Senior Physician, Liverpool Royal Infirmary; and Lecturer on Clinical Medicine, Liverpool University.

Mr. President and Gentlemen,—When I undertook to deliver an address on the above subject, chosen by members of this Society, I am afraid I did so with a light heart, but since I began to realise the difficulties of the subject, I have wished that I had demurred and selected another from the vast domain of heart disease dealing with hard facts as we find them, rather than prospective inferences. The subject of prognosis is one which was wisely and well cultivated by our forefathers, but in the present day so many disturbing influences have been introduced in the form of new methods of treatment that Nature does not now get a fair chance. Moreover, prognosis is not very profitable, many medical men considering that sufficient unto the day is the evil thereof, and consequently do not care to prophesy much more than twenty-four hours ahead. It is always wise never to prophesy until you know what is going to happen. Some say that it is always the unexpected which does happen, and so are careful not to give an evil prognosis until the end is near.

The public often insist on "knowing the worst," and occasionally they are quite satisfied when they hear it, but frequently they dispense with the services of the man who has given a fatal prognosis, and call in someone else who from sheer ignorance or cupidity may promise the impossible.

Personally, I think it is always right, whether it pay or not, to recognise the limits of our art and be fairly candid to the friends, if not to the patient. Many a good fee I have lost through candidly speaking the truth; I am afraid, therefore, I may be alluring you into dangerous paths where you may incautiously prove your own undoing. However, as general practitioners, in all cases of doubt or difficulty you can throw the responsibility on the consultant, though, in my opinion, the practitioner who sees the case from day to day, or month to month, or maybe year to year, is in a far better position to form an accurate prognosis than the consultant who may see the case a few times.

Fortunately, for one case where you have to give an unfavourable opinion you will meet with a score where the prognosis is good. There is no

(*a*) An Address delivered at the Southport Medical Society, January 27th, 1904.

other organ of the body more amenable to treatment than the heart, or more capable of adapting itself to altered circumstances, and there is no other organ the affections of which are better understood or more easily recognised. But in order to make a fairly accurate prognosis it is absolutely essential that you should have a clear conception of the condition of the organ. You must not only know the particular lesion affecting the heart, but also its extent, and the effect which it has on other organs of the body. As practical men I understand you wish me to give you methods of prognosis which can be applied to individual cases. Now, that is a very large order, and one which covers a very large scope; I must, therefore, assume that you are all well versed in cardiac diagnosis, and can form an opinion as to the extent of the lesion, *e.g.*, in a case of mitral stenosis you should not only diagnose the lesion, but also form an opinion as to the size of the orifice, the condition of the curtains, and the state of the muscle, the condition of the lungs, the right side of the heart, and the liver. Well, if you wish to read any articles on prognosis I can strongly commend to your attention the very able address delivered by Sir Dyce Duckworth at the meeting of the British Medical Association in Carlisle, and published in the *British Medical Journal*, 1896. Also a discussion at the Brighton meeting of the British Medical Association on a paper by the late Sir Andrew Clark, "On Cases of Valvular Disease of the Heart known to have existed for over five years without causing serious symptoms" (*British Medical Journal*, February 5th, 12th, and 19th, 1887). Among those who took part in the discussion may be mentioned Sir W. T. Gairdner, Dr. Clifford Allbutt, Dr. Bristowe, Dr. Leech, Dr. Frank Donaldson, and Dr. Thomas Oliver. You should be careful not to come under the stricture enunciated by Dr. Bristowe when he said:—"As to treatment, I am sometimes inclined to think it is a pity there are physicians; many persons would lead a happy enough life but for them. We should endeavour to keep up the health of the patients, and enable them to continue useful members of society. It is related of Dr. Murchison, seven or eight years before his death, that he found out that he had aortic regurgitation. He consulted as to what he should do, and he determined to go on enjoying himself as well as he could under the circumstances. It is certainly what I should endeavour to do, and it is what I recommend to patients." To a large extent I agree with the sentiments here expressed, but I consider the following sentences too pusillanimous to be worthy of an eminent physician: "Now I think it is quite time enough for persons to discover that they have heart disease when they begin to feel the effects of it. I do not believe that I have heart disease, I certainly hope I have not, but under no circumstances would I allow Sir Andrew Clark, or anyone else, to examine me for the purpose of finding it out."

I once examined a man for insurance who did not know that there was anything the matter with his heart, but he had a very atheromatous aorta, calcareous aortic cusps with moderately free aortic regurgitation, a hypertrophied left ventricle, and marked friction from white patches and early cardiac fibrosis. He only lived for about a couple of years after that, but I have no doubt if there had been early recognition, a good many of the degenerative changes might have been obviated by a careful life.

So far, gentlemen, I have been merely beating about the bush, but I hope you do not consider these preliminary remarks uninstructive. You may think that I am afraid to grasp the nettle for fear it may sting me, or to come to close quarters with my subject for fear you might discover my ignorance. Whatever may be the result of your verdict I must now try to give you my personal impressions on what appears to me a difficult subject. It was first suggested to me that I should give an address on the prognostic value of cardiac murmurs, to which I replied that they had no prognostic value except the general statement that as a rule the louder the murmur the less its importance. My friend and teacher, Sir W. T. Gairdner, in his "Clinical Medicine," 1861, said:—"The tendency of half instructed auscultators is to over-estimate the importance of the murmur, as a fact, and to under-estimate it as a means of investigation; to pay too much attention to the mere existence of the sound, and too little to the circumstances in which it occurs, and from this springs another tendency which is, to take too grave and sombre a view of cardiac murmurs generally, and especially of such as are loud and obtrusive." This is as true to-day as when it was written more than forty years ago.

In prognosis you have to carefully weigh the whole of the factors of the case, and not confine your attention entirely to the particular lesion from which the patient may be suffering. You must take into account the age, sex, temperament, habits, occupation, and hereditary proclivities of the individual. In the very young much depends on the care which they receive, while in the degenerative types of advancing years hard work lessens the chances of life, but it must be clearly understood that even hard work is not more pernicious than a life of luxury and indolence.

Pericarditis.—In ordinary sero-fibrinous pericarditis the prognosis of life is almost invariably good. Where there is much effusion the gravity is considerably increased. If the pulse become small, weak and irregular, the fluid should be immediately withdrawn. When the urgency of the case demands aspiration, do not delay as there is always a great risk of fatal syncope. In some of the mildest or less obtrusive cases, often a plastic gelatinous lymph is poured out, which glues the two surfaces of the pericardium together, and so the ultimate prognosis in such cases is worse than that of severe cases, where a coarse, honey-combed effusion of lymph takes place. In this latter variety adhesions are less likely to occur, and both the serum and lymph may eventually be absorbed. These forms of pericarditis generally occur in children, and the right side of the heart is much more involved than the left. The serum effused gravitates towards the back and lower part of the sac, and this prevents adhesions, while the heart is floated up, and thus the pericardial surfaces in front of the heart are brought into close contact; the adhesions cripple the right heart, and its development does not take place *pari passu* with the growth of the child. This becomes more marked if there have also been endocarditis involving one or both valves of the left side of the heart which demands hypertrophy

of the right ventricle; consequently these children rarely grow up to adult life, and the younger the child the worse the ultimate prognosis.

Pericarditis occurring with renal disease is generally a terminal affection, and almost necessarily fatal. Tuberculous pericarditis is also usually fatal, but I have a boy at present under my care who has had pericarditis, which I believe was tuberculous. After two tappings there has been no reaccumulation, and I do not think any of you could tell by examination that he ever had anything the matter with his pericardium. He also had double pleuritis with effusion, and now there is evidence of tuberculous mischief in the lungs. Hæmorrhagic pericarditis is associated with tubercle or malignant disease, and the result is usually fatal. Purulent pericarditis is generally septic, and associated with serious disease in other organs; the outlook is immediately grave, but some cases have recovered after incision and drainage. This treatment should be adopted at the earliest possible moment.

Pericardial Adhesions.—I take a much more serious view of all such cases than is generally adopted. Partial adhesions are no doubt compatible with fair length of life, but when the adhesions are so marked as to be easily diagnosed they have a great crippling effect on the heart, the weak right ventricle is much more involved than the left, and the trabeculæ of fibrous tissue penetrate between the muscular fibres and give rise to cardiac fibrosis. In mediastino-pericarditis the outlook is still more grave, as in such cases there is an enormous amount of fibrous tissue, not only fixing the two surfaces of the pericardium, but also anchoring the heart and involving both pleuræ. There is usually also perihepatitis, giving rise to the "sugar-coated liver." The so-called pulsus paradoxus which occurs in these cases I look upon as a favourable sign, as it is evidence that the respiratory pump is assisting the heart in carrying on the circulation. There is also often in these cases both mitral and tricuspid stenosis, and not infrequently pleural effusion and ascites. It is only with great care that the children thus affected—and the great majority are children—reach twenty years of age. Their growth and development are stunted.

Acute Endocarditis.—In simple acute endocarditis associated with rheumatism and chorea, the immediate prognosis is almost invariably favourable, even more so than in pericarditis, but in the majority of cases it leaves more or less crippling of one or more valves, leading to chronic valvular disease, with which we shall deal later on. The whole of the fibrous structure is vulnerable to the rheumatic poison, but the valves of the left side of the heart suffer most owing to purely mechanical causes, and the mitral valve, which is subjected to the greatest strain, suffers most. The beading and vegetations occur on the auricular surface of the valve just where the cusps are brought into violent apposition; and in the aortic valve the damage occurs on the ventricular surface, not at the edges of the cusps, but at the genu or bend where they are brought into forcible impact during the recoil of the aorta. In order to prevent the damage or limit its severity, it is absolutely of the greatest importance that the blood pressure should be kept at the lowest possible level compatible with life. As a prophylactic against valvular mischief, in my opinion the blood pressure should be kept low in every case of acute rheumatism. I believe that endocarditis can be diagnosed two or three days before the appearance of any murmur by the character of the first sound and the delay in the transmission of the pulse. Therefore, everyone who takes the trouble to carefully watch his cases of rheumatic fever has ample opportunity of limiting or lessening the valvular mischief and so improving the ultimate prognosis.

The right side of the heart usually escapes, although it is under the influence of the same poison, because its valves are not subjected to much strain, but in congenital heart disease the reverse happens, as during intra-uterine life the right side has the greatest amount of work to perform.

Infective or Ulcerative Endocarditis.—I have seen a few cases of infective endocarditis recover even when streptococci were found in the blood, but the great majority succumb, notwithstanding antistreptococcic serum. The duration is generally about six or eight weeks, but some chronic cases may last a twelvemonth. I have seen one case of infective endocarditis of the right ventricle which caused an aneurysm on each main division of the pulmonary artery; one of these ruptured, causing death.

Acute Myocarditis.—In pericarditis and endocarditis there is generally more or less involvement of the muscular structure, but acute myocarditis, involving a grave prognosis, is usually associated with such general diseases as diphtheria, typhoid fever, and pyæmia. In the former disease when the action is rapid, the sounds short and resembling each other in their *tic-tac* character, and the diastolic period lessened the prognosis is very grave. When the ventricles are dilated, the action slow, the first sound very short and the second rapidly succeeding it—thus indicating an only partial ventricular contraction—the prognosis is extremely grave. The early use of antidiphtheritic serum neutralises the poison, and lessens these effects on the heart.

In typhoid fever cardiac failure, owing to acute degenerative changes in the myocardium, is one of the commonest causes of death. In acute arsenical poisoning the myocardium often suffers, and may cause death. The same may be said for phosphorus poisoning and pernicious anæmia.

(To be concluded in our next.)

The Out-Patient Departments.

WEST LONDON HOSPITAL.

Dermatological cases under the care of
Dr. P. S. Abraham.

[Reported by Dr. G. N. Meachen.]

Case 1.—Erythema Iris.—The patient, a woman, æt. 38, came with an eruption on the hands, fore-arms, and knees, accompanied by considerable irritation. She had been subject to the complaint, on and off, for about five years. Her father died of phthisis, and three brothers and sisters had also died young from "bronchitis." She had never had any other illness. The attacks were generally preceded by headache and a slight feeling of malaise, and the bowels were habitually constipated. She never suffered from chilblains.

On inspection, the dorsum of the hands, both surfaces of the arms, and the front of the knees were seen to present numerous annular, concentric, raised, erythematous patches about the size of a sixpence, some of them being larger. A few were typically "target-like." The places on the knees, having under-

gone involution, were less characteristic. The patient was of a decidedly neurotic disposition.

This case illustrates several of the more important points met with in the erythemata as a class, namely, the nervous disposition of the patient, the hypersensibility of the cutaneous capillaries accompanied by impaired vaso-motor control, and the habitual constipation. The latter condition, by facilitating the absorption of toxins from the intestinal canal, has been shown to favour the appearance of many skin eruptions, notably those of an erythematous or eczematous nature.

The patient was given an aperient iron mixture and an anti-pruritic lotion of creolin for local application.

Case 2.—UNILATERAL LICHEN PLANUS HYPERTROPHICUS.—A man, æt. 24, presented himself with an eruption limited to the lower part of the outer aspect of the left leg. The history was that he broke his ankle about a year ago, and he believed that the spots began to appear around the seat of the injury a few weeks afterwards. Irritation had been considerable, though not intense. His general health was unimpaired.

The lesions consisted of several discrete, dark red, slightly scaly patches about the size of a shilling, raised above the surface of the surrounding skin, which was quite healthy, and showed a distinct heaping-up of the epithelium. They were grouped almost in a line parallel to the long axis of the limb, and were situated upon the lower third of the outer side of the leg and the ankle. The opposite limb was unaffected, neither were any other parts of the body covered by papules, the wrists, shoulders, and knees being perfectly clear.

The chief interest of this case lies in the peculiar unilateral distribution of the lesions, which were undoubtedly those of hypertrophic lichen planus. Superficially they might, perhaps, have been mistaken for syphilis, especially as their colour was of a somewhat "coppery" hue, but this criterion of the nature of cutaneous eruptions is one which is apt to be very deceptive, and he would be a bold physician who relied upon colour as an infallible diagnostic sign. Taken in conjunction with other signs, it may then be of some use.

With regard to the asymmetry of the eruption, it must be admitted that this is an unusual feature in lichen planus, but, recognising that the disease is most probably an inflammatory disorder of the skin of a neuropathic origin, it is not difficult to see that in this case the previous injury to the limb may have been sufficient to act as a determining factor in the distribution of the lesions in a predisposed individual. Generalised outbreaks of the disease have been known to follow nervous injuries, and, more rarely, a limited eruption has appeared in the course of the distribution of a cutaneous nerve. It is to the latter group that the present case would appear to belong.

The patient was given a lotion and an ointment containing creolin for local application.

Case 3.—DERMATITIS HERPETIFORMIS.—A married woman, æt. 38, came with an irritating eruption which she stated had been troubling her for about three months. She described the rash as beginning "with little blisters," which would break, leaving a sore, abraded surface. Around the umbilicus the eruption was likened to "mistletoe-berries." Her general health had suffered considerably during the past few weeks, the appetite and sleep both being impaired.

The lesions were seen to consist of small discrete vesicles, some of which had been severely scratched, and, consequently, presented some blood crusts upon their apices. The face, arms, and to a slighter extent the chest, were affected. A group of vesicles upon the inner side of the left wrist had run together and had progressed to superficial ulceration. The feet were not affected. The chief subjective symptom was that of itching.

The diagnosis of dermatitis herpetiformis of Duhring was based upon the character and grouping of the lesions, which were fairly symmetrically distributed, upon the typical history of their mode of appearance, together with the intense pruritus which they occasioned. The disease, which is distinctly a rare one, is generally characterised by considerable impairment of the patient's general health, and this is well illustrated in the present case, loss of appetite, weakness, and some irritability of disposition being marked. Treatment is not always satisfactory, the affection frequently showing an obstinacy to both internal and external medication, and sometimes becoming chronic. Relapses are also common, especially if the patient gets run down in health.

A mixture containing iron and strychnine was prescribed, together with a simple anti-pruritic lotion and ointment.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXXIII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE MALDON SANATORIUM.

IT is doubtless well that there should be all sorts and conditions of sanatoria for phthisical subjects, provided, however, that each makes the care of the patient the first object, and maintains a course of treatment which is thoroughly rational and based on a clear recognition of hygienic principles. Much in the institutional treatment of consumption must still be considered to be in the experimental stage. It is well, therefore, that as far as definitely ascertained scientific procedure will permit, there should be variations in detail and differences in non-essential routine. It is necessary to remember that for many patients, social, financial, and what we may term local considerations must be allowed to control to a great extent the selection of a sanatorium. It is not our intention at the present time to discuss the various factors which go to make a satisfactory sanatorium, but it is necessary to insist that medical control is essential. The dominant mind in every establishment should be that of the responsible medical attendant.

In our present series of articles we have had to deal with free public institutions, sanatoria built and maintained by co-operative effort, establishments semi-public and semi-proprietary, and not a few conducted purely as private ventures. Advantages and dis advantages are inseparable from any method of control, and the advising medical practitioner must exercise much judicious care in his selection of an establishment for his cases.

Many of the small and private establishments which adopt the title of sanatorium are really hygienic homes, rather than specially-constructed buildings. They, however, in many cases meet a real need, and provide useful education in the application of natural methods, and oftentimes the results appear to be as satisfactory as those attained in the more ambitious and very expensive new sanatoria.

The Maldon Sanatorium is an example of the small proprietary hygienic home. Maldon is a small country town and agricultural centre in Essex, on the river Blackwater, some ten miles from the sea, and one and a half hours' journey from London. Although much of the country in the immediate neighbourhood is low-lying, Maldon is picturesquely placed on the hill and its slopes, and the sanatorium lies at one extremity of the town, fairly well elevated, distant from the high road, pleasantly secluded, and with an attractive outlook.

The sanatorium is really an adapted old country house. It was once evidently a moated grange, and even still a moat filled with water surrounds a considerable part of the house. A portion of the building would appear to be some three of four hundred years old, while other parts have manifestly been added in the last century. The whole place has an old-world aspect. A verandah runs along the south side of the house.

The grounds are some five acres in extent, well-

wooded and sheltered, and include pleasant gardens, orchard, outhouse premises. Adjacent is a farm, while the neighbouring country offers ample opportunities for walks, and pleasant drives can be taken in the district.

The rooms are old-fashioned, but clean and airy, simply furnished, and six contain two beds. There is another room available for a single case. Some thirteen or fourteen patients can be accommodated. The dining-room is of fair size, and is also used as a recreation apartment when the patients cannot venture out of doors.

There is a somewhat elementary shelter in the grounds, and additional liegehallen might be secured with advantage. The meals are arranged to meet the needs of the class of patient received. Three meals a day are given, and at each a pint of milk is supposed to be taken.

There is no resident doctor, but Dr. W. E. Facey, a practitioner in Maldon, attends daily and at such other times as he may be desired. Miss Wilson superintends the nursing and general management of the patients, and is assisted by a probationer.

The establishment is evidently conducted with a view to strict economy, but as far as structural and other conditions will allow, satisfactory results should be attained.

The fees are £2 2s. to two and a half guineas weekly, "exclusive of wines, drugs, personal laundry and a special nurse, should one be required."

The sanatorium is near to Maldon East Station, and patients should avoid being taken to Maldon West, which is over a mile distant and at the other side of the town.

There is a fairly convenient service of trains from Liverpool Street Station on the Great Eastern Railway, but a change has to be made at Shenfield Junction.

THE GALWAY X-RAY CASE.

A case of much interest and importance to medical men occupied the Law Courts in Dublin for a considerable portion of the last two weeks. The action—M'Cullagh *v.* the President and Professors of Queen's College, Galway; William Haire, of New Line, Galway; and Nicholas W. Colohan, M.D., the Villa, Galway—was one in which Thomas M'Cullagh, an infant, suing through his father, sought to recover damages for personal injuries caused by the alleged negligence of defendants in the use of certain electrical apparatus. Plaintiff's claim was in respect of injuries alleged to have been caused by the Röntgen rays in the treatment of an injury sustained to the knee. Defendants denied the acceptance of any employment as to the treatment of plaintiff, or that there was any negligence or unskilfulness in the treatment of his injuries.

In counsel's opening statement it was alleged that the boy, who had got a needle in his knee, was taken to the late Dr. Quirke, of Galway, for treatment in December, 1902. This gentleman sent him to be X-rayed by a man named Haire, mechanical assistant to the Professor of Natural Philosophy in the Queen's College. Haire took a photograph which did not reveal the presence of the needle. Dr. Quirke then fell ill, and the boy was taken to Dr. Colohan, who again sent him to be photographed. Several photographs were done, and during the time they were taken a burn resulted.

The mother of the boy gave evidence to the effect that the boy was "under photograph" for half an hour at a time, and that "the piece of metal inside the globe became red as burning coal." The child was treated for the burn in the Galway Hospital, and then brought to Dublin in April, 1903. He was first taken to Mr. McArdle, F.R.C.S., who did not examine the knee, but sent him to Mr. Milford Lewis, a non-medical man, who makes a practice of X-ray work. Mr. Lewis, however, on seeing the burn, refused to take the photograph. The mother next took the boy to Mr. Lentaigne, who took the boy into the Mater Misericordiæ Hospital. The sore had now skinned over, but the boy was lame. She admitted that Dr. Colohan was most attentive to the boy.

The boy's sister gave evidence to the effect that Dr. Colohan had himself screened the knee, that he had put the tube "against the sore," and that in taking the photographs the tube was two or three inches from the knee.

Mr. Milford Lewis, professional X-rayist, said that he considered that anything less than six inches between the tube and the flesh was dangerous. The time of exposure with modern tubes would be a half to one and a half minutes. For an old-fashioned instrument and an old tube, allowance had to be given.

Dr. W. Haughton, Surgeon to Steevens Hospital and University Demonstrator of X-rays to Trinity College, said that the ordinary working distance was from twelve to fourteen inches. He usually worked at eighteen inches for a knee. His experience was that if he did not get a photograph in five miuntes he would not get one at twenty-five, and he habitually began with an exposure of one minute. Any tube requiring twenty-minutes' exposure was an improper tube to use. All low tubes were liable to cause inflammation of the skin. He considered that X-rays in careful hands were not dangerous.

Dr. R. L. Lane-Joint gave corroboratory evidence, and demonstrated the manner in which an X-ray examination was carried out.

For the defence, counsel urged that some fifty radiographs had been taken by Haire without accident, and that therefore Dr. Colohan was justified in sending the boy to him for examination. A medical man was not an insurer nor bound to effect a cure, and Dr. Colohan had acted throughout, as was admitted, with the interests of the boy at heart.

Mr. Haire then gave evidence. He admitted that, owing to former photographs having been without result, he had exposed the plate for thirty minutes, but stated that it had never been within two inches of the skin. Dr. Colohan did not interfere with the tube in any way or take a photograph on his own account. The platinum in the tube never became red-hot.

Dr. H. Lewis Jones, Medical Officer in charge of the Electrical Department, St. Bartholomew's Hospital, stated that he had examined and tested the tubes used in this case, and found little sign of use, and no sign of wear and tear. The platinum target showed no symptoms of injury. With the coil used in this case the minimum distance from the skin to the globe would be eight inches, and ten minutes would be a reasonable exposure. If pain was felt during an exposure, he would consider something wrong either with the patient or the instrument.

Mr. Hall Edwards, Surgeon in charge of the X-ray Light Department in Birmingham, had seen worse burns than the present one. A reasonable working distance would be about eight inches. On being shown a plate taken of the boy's knee, he considered that it was a good one and could not have been taken at a distance of two inches.

Sir Charles Ball and Sir Thornley Stoker also gave evidence.

Dr. O'Donnell, physician to the Mater Hospital, said that his average working distance was about six inches. He had often in the past exposed for twenty-five minutes, and sometimes for thirty-five, but now this time was greatly shortened.

Dr. Colohan gave evidence of his treatment of the child. He did not personally know anything of the use of the rays, but had sent patients previously to Haire, and had received excellent photographs. He had never himself rayed the child. The globe was to the best of his belief six or eight inches from the knee, and the exposure from twenty to twenty-five minutes. The globe never touched the boy's knee. One photograph was taken which showed the needle, but on making another effort to get supporting evidence it could not be seen.

Mr. McArdle gave evidence. He considered that the machine produced in Court for demonstration

purposes was not of a modern type. He had exposed his own hand for thirty-five to forty minutes at a distance of four to six inches without any injury. He had ordered the boy to be X-rayed without seeing the sore, as the X-rays would do no harm.

Further evidence was given, and, after the speeches of counsel, the Judge, in his charge, put certain questions to the jury. These, with their answers, are as follows :—

1. Were the Queen's College, Galway, and Haire, or one, and which of them, employed for reward to photograph by X-rays in December, 1902, and in April, 1903 ? —Haire was so employed, College was not.

2. Was the sore caused by the rays ?—Yes.

3. Were the rays negligently applied as regards : (*a*) Distance ?—No. (*b*) Duration of each exposure ? —No. (*c*) Consecutive multiplication of exposures ?— No. (*d*) The type of machine ?—No.

4. Was the sore caused by the operation—(*a*) Of December 15th ?—Cannot say which. (*b*) Of December 23th and 27th ?—Cannot say which. (*c*) Aggravated by those in April ?—No.

5. (*a*) Did the operations of Dr. Colohan, for which Haire is not responsible, contribute to the sore ?—Yes. (*b*) Did the operations of Haire, for which Dr. Colohan is not responsible, so contribute ?—Yes.

6. (*a*) Was Haire negligent in applying the rays ?— No. (*b*) Was Dr. Colohan negligent in applying or superintending ?—No.

7. Before the rays were applied in April, was (*a*) Dr. Colohan negligent in not diagnosing the sore as caused by X-rays ?—No. (*b*) Was Haire so negligent ?—No.

8. (*a*) Was Dr. Colohan negligent in applying the rays in April after the sore appeared ?—No. (*b*) Was Haire so negligent ?—No.

9. To what damage, if any, is the plaintiff entitled ? —None.

10. (*a*) Is any and what amount of such damages attributable to acts of Dr. Colohan only ?—Not answered. (*b*) Is any and what amount thereof attributable to acts of Haire only ?—Not answered.

On these findings a verdict was entered for the defendants.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEBRUARY 12TH, 1904.

DR. FREDERICK TAYLOR, President, in the Chair.

DR. SIDNEY PHILLIPS reported a case of

FIBROID DISEASE AND CALCULI OF THE PANCREAS.—JAUNDICE AND SUBSEQUENT DIABETES.—DEATH FROM COMA.—NECROPSY.

The patient was a married woman, æt. 26, who, at Christmas, 1901, began to suffer with epigastric pain. In February, 1902, jaundice appeared with absence of bile from the stools. There was no history of biliary colic. An exploratory operation was performed at St. Mary's Hospital by Mr. Edmund Owen on April 3rd, when a great enlargement, judged to be non-cancerous, of the pancreas was found. On June 14th, 8 per cent. of sugar was present in the urine, and six months later the jaundice entirely disappeared, but the diabetic symptoms progressed. On January 25th, 1903, she was attended at her home by a medical man for diabetic coma, from which she died on the following day. A partial autopsy was obtained. The pancreas was much enlarged and presented a considerable degree of fibroid change throughout, with numerous small calculi of varying size, so that sections of the organ cut gritty. Microscopically, there was almost complete replacement of pancreatic tissue by fibrosis, and destruction of the islands of Längerhaus. The occurrence of the jaundice was explained by obstruction of the common opening into the duodenum of the pancreatic and bile-ducts. The glycosuria was of the type usual in "pancreatic diabetes."

DR. NORMAN DALTON inquired whether the pancreas was smaller at the autopsy than at the time of operation, and pointed out that its diminution in size was probably analogous to that of a cirrhotic liver.

MR. LEONARD A. BIDWELL remarked that the gall-bladder was generally distended in cases of chronic pancreatitis. He had operated upon four cases of this affection, and in none of them was glycosuria observed after the operation. The cause of the jaundice in the present case might have been due to a calculus which had been originally impacted in the ampulla of Vater.

THE PRESIDENT asked what were the conditions of the motions.

DR. WILLIAM PASTEUR referred to the case of a man recently under his own care with increasing jaundice, which suggested cirrhosis of the liver. At the autopsy a scar was found exactly opposite the orifice of the pancreatic duct in the duodenum. All the ducts in the pancreas itself were dilated, but there was no fibrosis.

DR. SIDNEY PHILLIPS replied that there was always some difficulty in estimating the size of the pancreas. He did not consider that there was any evidence of gall-stones in his case, and he believed that pancreatic calculi were quite capable of producing jaundice.

DR. NORMAN DALTON narrated

TWO CASES OF MALIGNANT ANÆMIA,

due, apparently, to defective formation of the red corpuscles, and associated with caries of the teeth and suppuration of the upper jaw. The first case was that of a man, æt. 21, suffering from debility, pallor, anæmic bruits, epistaxis and other hæmorrhages, and vomiting. The disease lasted only eight months, and there was no post-mortem. There was no enlargement of the spleen or lymphatic glands. The interest centred in the urine, in the suppurative lesions, and in the blood. The urine was never high-coloured. The teeth were carious, and there was an alveolar abscess which, after incision, left a sinus in the hard palate. Otorrhœa was also present. The blood showed progressive oligocythæmia, the red discs falling from 1,200,000 per c.mm. on admission to 393,720 three months later. The hæmoglobin was also diminished, and there was marked leucopenia, the lymphocytes being in excess of the polynuclear cells.

The second case was that of a girl, æt. 17, who had lived in extreme poverty. She had been ailing for some time, but the illness only became acute three weeks before she was admitted to King's College Hospital, where she died five days later. The urine was pale, the teeth were carious, and there was an abscess in the upper jaw from which pus was constantly oozing. The blood only contained 816,000 red cells per c.mm., 17 per cent. of hæmoglobin. The leucocytes numbered 3,500. At the autopsy, there were subserous and submucous hæmorrhages. There was no free iron in the liver, and the red marrow was fatty. In neither case could surgical treatment be undertaken on account of the tendency to hæmorrhage. Dr. Pasteur had described an exactly similar case, but there was no suppurative lesion.

DR. WILLIAM HUNTER agreed that the cases corresponded in a remarkable way to those which he had described as "septic anæmia," which had been previously included under the title of pernicious anæmia, but were distinguished therefrom by the intense degree of anæmia, the presence of megaloblasts, the frequently associated gastric or intestinal symptoms, the absence of the hæmolytic changes in the urine, the presence of a low type of pyrexia, the absence of the bone marrow changes generally seen in true Addisonian anæmia, and the grave prognosis attached thereto, unless the focus of suppuration could be removed.

DR. WILLIAM PASTEUR referred to the case which he had read before the Society last November, in which hæmolysis was excessive, but there was no suppurative

lesion. He therefore concluded that, for the present, his case must stand alone.

Dr. LEONARD S. DUDGEON inquired if streptococci were present in the blood previous to the injection of anti-streptococcic serum.

Dr. F. PARKES WEBER understood Dr. Dalton to say that something more was necessary for the production of anæmia than sepsis alone.

Dr. DALTON replied that he considered that persons with carious teeth were always in danger, because at any moment an unknown factor might supervene and convert a condition of simple ill-health into a malignant form of anæmia which was rapidly fatal. He thought that Dr. Hunter's phrase of "septic anæmia" a little unfortunate, as tending to cause some confusion with the true Addisonian anæmia, in which a special form of sepsis occurred on the tongue. The blood in his case was not examined for streptococci.

Mr. J. JACKSON CLARKE described a case of excision of the neck of the lower jaw for temporo-maxillary ankylosis. The patient was a woman, æt. 35, on whom, four years ago, he had performed this operation on both sides for ankylosis following an infection, probably gonorrhœal in origin. She could now separate the edges of the incisor teeth three-quarters of an inch, and could masticate with comfort.

Mr. T. HORROCKS OPENSHAW referred to cases of his own in which he had resected both condyles with good results.

Mr. OPENSHAW also exhibited three cases of fracture of the bones of the leg treated by immobilisation in Hoeffitcke's apparatus and a modified Hessing's splint-case appliance.

Mr. EDRED M. CORNER read notes of two cases of primary and secondary tuberculosis of the thyroid gland. In the first case, a girl, æt. 9, the condition was found during life, an abscess in the right lobe and a sinus leading to a diseased left lobe being present. The wounds refused to heal until thyroid extract was administered. The child died seven months later from general tuberculosis. The second case was discovered post-mortem, as a caseous mass in the right lobe of the thyroid, in a woman who had died of pulmonary thrombosis and phthisis. The condition was really more of a clinical curiosity, as localised tuberculous deposits in the gland were extremely rare.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FEBRUARY 3RD, 1904.

Professor CHIENE, President, in the Chair.

MR. DOWDEN showed (1) a patient after severe laceration of the arm; and (2) after osteo-myelitis of the tibia and secondary infection of the knee-joint.

Mr. ALEXIS THOMSON showed a boy, æt. 11, who had suffered from infantile paralysis at the age of three, peronei and extensor digitorum being chiefly affected, and the resulting condition being one of talipes equino-varus. Double division of the tendo-Achillis, along with transplantation of the tendon of the tibialis posticus to that of the extensor digitorum, had led to decided improvement.

Mr. SCOT SKIRVING showed the skull of a patient exhibited before the Society five years ago, showing total necrosis of the frontal bones and partial necroses of the parietal bones from syphilis.

Dr. LOVELL GULLAND read a paper on

THE GLYCOGEN REACTION OF THE BLOOD.

This reaction was first described by Ehrlich in 1883 as occurring in pus, but later research, both in Germany and America, had greatly extended its range of usefulness, although so far it had been somewhat neglected in this country. The *technique* was very simple, an air-dried blood film being placed on a drop of the staining reagent (iodine, 1 grain; potassium iodide, 3 grains; distilled water, 100 c.c.) on a slide, and examined directly with an oil immersion lens. A white light—daylight, or that from an incandescent gas burner—should be used, as the reaction was much less easily seen by yellow light. In normal blood the red corpuscles stain orange yellow, the leucocytes a faint lemon yellow. The lymphocytes are almost invisible, except from their different refractor index; the eosinophiles can always be made out on account of the high refractive power of their granules, while the polymorphonuclears are darker on account of their closely-set granules. Under normal circmustances the neutrophile polymorphonuclears show no red or brown stain, but a certain amount of extra-cellular glycogen is present in the blood plates. This is very variable in different diseases; it is increased in diabetes only, and is of no practical importance in diagnosis. A positive reaction, *i.e.*, presence of glycogen in the polymorphonuclear leucocytes, is often of great diagnostic value. The reaction is occasionally found in the myelocytes and basophiles (in rare cases of leukæmia), but practically it may be disregarded except when occurring in the polymorphonuclears. In these all glycogen may give rise to three different degrees of change—(1) a brown colour, (2) fine brown granules, (3) coarse granules with peripheral brown masses like pseudopodia. These glycogen granules are paraplastic, and have no connection with the ordinary neutrophile granules, which are simply nodes in the cytoplasmic reticulum; if, therefore, the former assume any dimensions, they can no longer be contained in the meshes of the reticulum, and are extended towards the periphery (pseudopodia). These granules do not consist of pure glycogen, but of a combination of glycogen with proteid. They are not found in the cells of the bone marrow, but are more abundant in emigrated leucocytes, and can, therefore, be well studied in films of pus. In the blood the percentage of cells giving the glycogen reaction varies from 5 per cent. of the neutrophile leucocytes upwards, and if after looking over two or three hundreds of these cells no glycogen is found, the reaction may be said to be negative. The degree of the reaction varies roughly according to the severity of the cause, and it is found under four principal conditions—(1) in anæmia, (2) in severe disturbances of respiration, (3) in toxæmia, (4) in suppuration. In various forms of anæmia it may be well marked, but it is doubtful whether anæmia *per se* has anything to do with it. It is not of any diagnostic importance in this disease. Any obstruction to the respiration—cardiac or pulmonary disease, &c.—produces it; but as soon as the embarrassment of the circulation is at an end, the reaction disappears. In toxic conditions following sepsis, malignant disease, &c., it is also present. In none of these conditions, however, is the reaction of more than pathological interest; its great clinical importance is its constant association with suppuration. Experimentally it has been produced by the injection into animals of staphylococci and streptococci, the bacilli of typhoid, diphtheria, and anthrax, the bacillus pyocyaneus, &c., while the organisms of tetanus and fowl cholera give negative results. Clinically, it is met with in man most markedly in infections in which there is a marked exudation. Thus a positive reaction is got early in pneumonia, and disappears with the crisis. It is also found in cases of broncho-pneumonia, but not in bronchitis, and hence may serve to assist in the diagnosis between the two conditions. It is also found in empyema, but not in dry or serous pleurisy, and in abscess and gangrene of lung. It is a much more constant accompaniment of all advancing suppurative processes than is a leucocytosis, and generally is equal in amount to the severity of the constitutional disturbance. The size of the abscess does not affect it; whenever an abscess is drained the glycogen reaction goes, only to return if drainage be interfered with. It does not occur in tuberculosis. In gangrene of the bowel, peritonitis, and appendicitis it is a better test than leucocytosis, and even than a relatively high polymorphonuclear count. It occurs very soon after the onset of appendicitis or peritonitis—within three, twelve, or fifteen hours.

Dr. STUART MCDONALD read a paper on

A CASE OF GENERAL STREPTOTHRIX INFECTION.

At the outset he pointed out that the case was almost unique. Most of the records showed that in

previous cases the infection had been local, and there had been difficulty in cultivating the organism. In his case the streptothrix had been cultivated quite readily, and inoculations into animals had given positive results, so that it had been easy to identify it. He hoped to show that it bore certain suggestive resemblances to tubercle. Some writers referred to such cases as actinomyces infection, but it was better to reserve the name for the specific variety actinomycosis. After referring to the literature of the subject the speaker said that the streptothrix found in his case seemed to be identical with that found by Eppinger in the pus from a cerebral abscess in a patient, who also showed pseudo-tuberculous lesions of the apices of the lungs and caseating glands. His case seemed to be the only one which had so far occurred in this country in which the streptothrix Eppingerii had been found. The patient's history, shortly, was as follows: A woman, æt. 65, had been complaining of a cough for six months, and had been for five weeks confined to bed. There was no expectoration. On admission to hospital she was drowsy, temperature 99·8°, pulse 112, respiration 28. There was consolidation of the left lung, paralysis of the left arm, conjugate deviation of the eyes to the right, and increase of the knee-jerks. She became comatose, and died two days later. As bearing on a possible source of infection, it was noted that her house was opposite a stable yard, and that quantities of chaff, &c., were always blowing about. The post-mortem revealed recent pleurisy, and an appearance of the lungs like general tuberculosis, though the lesions seemed more pyæmic than tubercles usually are. At the surface of the lung some of them had actually broken down into small abscesses. There was an abscess in one kidney and pyelitis, and multiple abscesses in the brain. Cultures from the abscesses gave a pure growth of streptothrix, very like, but not absolutely identical with, S. Eppingerii. Inoculation of guinea-pigs and rabbits showed that the organism was virulent to these animals. In some instances it produced lesions like those of pyæmia, in others like those of tubercle. It may be that by using an attenuated culture, changes even more like those of tubercle would be produced. The streptothrix stained by Gram's method; it was acid-fast, like tubercle, and alcohol-fast. Under certain conditions the cultures tend to give rise to bacillary and coccal forms of the streptothrix, and the former of these, being acid-fast, in many instances closely resembled tubercle bacilli. As to the lesions in the organs, the chief point was the amount of fibrinous exudation, which in some places even showed signs of organisation. The paper was freely illustrated by lantern slides, microscopic preparations, illustrative cultures, &c.

Dr. J. V. PATERSON read a paper on

GLAUCOMA AND THE GLAUCOMA THEORIES,

which will be found on page 165.

Mr. GEORGE BERRY discussed the relations of the glaucoma theories to treatment. He thought operations based on such hypotheses had been less successful than those which had been discovered empirically. Clinical investigation of the arterial system had not in his hands led to any very definite conclusions on account of the imperfections of the instruments in use at present.

Dr. George Mackay also discussed the paper, and Dr. PATERSON replied.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, FEBRUARY 4TH, 1904.

JAMES BARR, M.D., F.R.C.P., President, in the Chair.

HOT-AIR CAUTERY.

Dr. GROSSMANN gave a short account of the hot-air cautery introduced by Dr. Hollander, of Berlin, and showed a modification adapted for ophthalmic surgery. He had employed it with satisfactory results in angioma of the lid, in corneal ulcers and similar affections. He considered it particularly valuable in cases of conical cornea. The different degrees of heat could be easily regulated, and the results were superior to those of actual cautery.

CHRONIC POISONING FROM ANTIMONY.

Dr. LESLIE ROBERTS exhibited a patient, a compositor, suffering from chronic poisoning by antimony and lead. The symptoms were sweating, tenderness of palms and soles, and pains in the muscles of arms and back. The patient had given up work on account of the tenderness of the fingers. The palms were pinkish-red, and drenched with perspiration. Scattered over them were small flat smooth papules. Microscopic examination showed the rete to be hypertrophied, the sweat-ducts much dilated, and the capillaries congested. The condition of the palms was like that seen in some forms of arsenical poisoning. The linotype metal was found to be composed of tin, antimony, and lead. The urine was free from albumin, but contained lead. The man had not suffered from colic. The plumbism seemed to have been modified by the antimony.

INTRA-VESICAL SEPARATION OF THE URINE.

Mr. ROBERT BICKERSTETH read a note on the intra-vesical separation of the urine from the right and left ureters as an aid to the diagnosis. He showed the "separator" introduced by Dr. George Luys, of Paris. He had used this instrument for the last six months, and he showed specimens of separated right and left urines, which proved the method to be of the greatest utility. The bladder is washed out and emptied before passing the "separator." In from fifteen to twenty minutes sufficient urine can be collected from each ureter to estimate the relative efficiency of the kidneys. A general anæsthetic is not necessary, for after the introduction of the instrument the patient should be placed in the sitting posture.

Mr. PAUL endorsed all that had been said in favour of the instrument. In one case, from the clinical symptoms he had decided to operate upon the right kidney, but fortunately the "separator" demonstrated that this was the better kidney of the two.

Mr. GEORGE HAMILTON said that in certain cases of renal hæmaturia, owing to the blood clotting, the utility of the instrument might be limited.

Mr. MONSARRAT had been greatly impressed with the value of the instrument.

PUERPERAL SEPTICÆMIA.

Dr. NATHAN RAW read a paper on the pathology, bacteriology, and treatment of puerperal septicæmia, with special reference to the value of antistreptococcic serum, based on an observation of sixty-one cases. The disease in no way differed in origin and in symptoms from that of any other infective and septic process, and was not peculiar to the lying-in state. The micro-organisms found in his series were as follows:—

Cases.	*Micro-organisms.*
27	Streptococcus pyogenes.
6	Staphylococcus aureus.
13	Mixed infections.
11	Bacillus coli communis.
1	Diphtheria.
3	No growth of organisms.
Total 61	

It was of the highest importance that before the serum was employed it should be demonstrated beyond doubt that the infection was streptococcal. This could readily be done by staining a little of the secretion from the uterus or, in advanced cases, from the blood. It was, however, difficult to recover streptococci from the blood unless taken from a vein in large quantity, say 5 c.c., and then they were not always found. His experience went to show that the serum was of the greatest possible value in pure streptococcal infections, if employed early in the disease. It reduced the temperature and the pulse-rate, and the patient passed into a condition of quiet and sleep. The dose he employed was 20 c.c., twice or thrice daily, and continued for several days. He had never known any harm or bad symptom arise from its use, if obtained from a trustworthy manufacturer, and with a bacteriological guarantee of its purity before use. *Table I.*—Total number of cases under observation, 61; recovered, 32;

died, 29; death-rate, 48 per cent. *Table II.*—Number treated with serum, 37; recovered, 24; died, 13; death-rate, 36 per cent. *Table III.*—Number treated without serum, 24; recovered, 8; died, 16; death-rate, 60 per cent. Several patients in Table III. were admitted in an advanced stage of the disease, when obviously no treatment would be of avail.

Dr. Gemmell said he had not felt confidence in the serum treatment, mainly because he feared to use it unless he felt certain that the specific germ was in the blood, and any examination of the blood must be made frequently and a sufficient quantity taken from a vein. Even so, the result was usually negative, and the procedure alarming. The presence of streptococci in the lochial discharges was not sufficient indication for the use of the serum.

Dr. Briggs had frequently used the serum, but had grave doubts as to its real utility. If the benefits claimed for its use in puerperal septicæmia were undoubted, it should also be of great value in surgical septicæmia and in ulcerative endocarditis.

Dr. Llewellyn Morgan pointed out that as no harm had come to any patient through the use of the serum, and as in many cases undoubted good had followed its use, therefore every case of septicæmia should be given the chance of the possible benefit.

Dr. E. T. Davies drew attention to the fact that though in maternity hospitals puerperal septicæmia was seldom or never met with, yet the incidence of septic infection in private practice remains appallingly common, thus proving that private practitioners and midwives do not pay the same attention to surgical cleanliness as obtains in hospital practice.

Dr. Grimsdale said the practical point to emphasise was that puerperal fever is a preventible disease, yet it is at present more prevalent in private practice than it was thirty years ago. Most importance should be directed to prophylaxis, and, secondly, to early diagnosis. Early diagnosis and efficient local treatment were the chief elements in success.

Dr. O'Flaherty said in many cases the source of infection was to be found, not in the uterus, but in some diseased pelvic organ, which had been injured during labour.

Dr. Grunbaum observed that in spite of the relative feebleness of antistreptococcic serum, it should always be given when the clinical symptoms pointed to puerperal septicæmia, whether streptococci were found or not. The administration should be continued for some time after apparent cure, on account of the feeble immunisation attainable against streptococci by man. Recent improvements in the manufacture of the serum made its use much more hopeful.

THE OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Meeting held Monday, February 1st, 1904.

The President, Dr. Thomas Barr (Glasgow), in the Chair.

Introductory Address.

The President, reviewing the work of the last session, remarked on the fact that a very large portion of the communications dealt with suppurative diseases of the ear and their complications, and suggested that the Society might well devote a part of its time to a study of such affections as sclerosis of the middle ear, diseases which might not directly endanger life, but which made life almost unbearable. It would be of great advantage to otologists to have authoritative guidance as to the comparative utility of the numerous methods of treatment in vogue.

Mr. C. H. Fagge exhibited a specimen of "atresia auris congenita." The tympanic membrane, ossicles and osseous meatus were absent on both sides, and no cavity resembling a mastoid antrum could be found.

Dr. Tilley raised the question of the possible absence of the antrum in adult ears, which were otherwise anatomically normal.

Dr. Milligan (Manchester) read a paper on the etiology and treatment of labyrinthine suppuration. The invasion of the labyrinth from the middle ear or antrum took place generally through the foramina ovale and rotundum and the external s.c. canal. Extensions from the labyrinth were most frequent to the cerebellar fossa by way of the internal auditory meatus, the cochlear and vestibular canals, but might reach the middle cerebral fossa through the prominence of the s.s.c. canal. Facial paresis, vertigo, loss of bone conduction, and deep-seated pain occurring in a case of middle ear suppuration would lead to a suspicion of labyrinthine suppuration. Mixed cases of labyrinthine and intracranial disease (especially suppurative meningitis, extradural abscess and cerebellar abscess) were not uncommon, and the differential diagnosis would depend largely on examination of the outer wall of the labyrinth. The presence of optic neuritis and focal symptoms would favour a diagnosis of intracranial abscess; mere "pressure" brain symptoms, on the other hand, might be caused by simple meningeal exudation excited by the labyrinthine disease. Dr. Milligan's paper was illustrated by cases, and by lantern slides of the temporal bone.

Discussion of the paper was adjourned, at the suggestion of Mr. Ballance, to the next meeting.

Mr. W. H. Kelson showed a patient with a cicatricial condition of the tympanum and meatus, following prolonged suppuration of the middle ear. On examination with a speculum the meatus presented the appearance of a hollow cone, the ear being free from suppuration and the other one normal. Members present advised leaving well alone.

Mr. Hunter Tod showed a specimen of sarcoma removed by operation from the external meatus of a woman, æt. 67. The specimen was referred to the Pathological Committee.

Mr. Hugh E. Jones exhibited a portable surgical hand-motor, designed to obviate the necessity for carrying about an electrical accumulator. The motor will be made for sale by Messrs. Mayer and Meltzer, who have fitted it with their patent flexible cable and aseptic hand-piece.

Mr. W. C. Bull showed a left temporal bone obtained from a man, æt. 21. Purulent otorrhœa twenty years, no intracranial symptoms, facial paralysis fourteen days, complete postaural operation; bone around tympanum and antrum found blackened, and an opening into the Fallopian canal discovered. Death occurred three days after operation from an undetected cerebellar abscess.

ULSTER MEDICAL SOCIETY.

The fourth general meeting of the Session was held in the Medical Institute, Belfast, on Thursday evening, February 4th, the President, Dr. John Campbell, F.R.C.S., in the Chair.

On the motion of Dr. Houston, seconded by Dr. O'Neill, a motion, recommended by the Council of the Society, was passed supporting the resolutions recently sent to his Majesty's Government by the Council of Queen's College, Belfast, urging the necessity for the better equipment of the college.

Dr. J. C. Martin (Portrush) showed a pathological specimen of atheromatous and aneurysmal condition of the abdominal aorta and both iliac arteries. The man from whom the specimen was taken died at eighty-seven years of age, not from any of the usual terminations of aneurysm, but from asthenia.

Dr. A. B. Mitchell, F.R.C.S.I., showed a case in which the whole of the right clavicle had been resected. There was very good movement and power in the right arm.

Dr. Mitchell also opened a discussion on the surgical treatment of malignant tumours of the breast. His paper was very fully illustrated by lantern slides showing the anatomy of the gland and the histology of some of the tumours operated on, and by photographs of some of his cases and pathological specimens. Dr. Mitchell said that he had tried the Röntgen rays and Colley's fluid, and had come to the conclusion that an operation was the best treatment. His rule was "Operate—operate early (do not wait till the

tumour is painful); operate completely." He advocated the removal of the pectoralis muscle, not so much because it might be infiltrated with the growth as that its removal enabled him to clear the axillary and other lymphatic glands more completely away. He sounded a note of warning as regards the age of the patient; it had been taught that carcinoma of the breast was not common below thirty years of age. He did not altogether agree with this teaching, and not only had he found such malignant tumours below that age, but he had found excessive malignancy in such as did occur.

Professor SINCLAIR, F.R.C.S., said he agreed with this statement as regards patients below thirty years of age. He also had lost confidence in Röntgen rays and Colley's fluid; the latter, some time ago, he had found not only do no good, but do absolute harm. He usually preferred a Mitchell Banks operation, and removed the sternal part of the pectoralis major to get at the glands in the subclavicular triangle. It was very necessary to remember the triangular shape of the organ, as in old days the angles of the mamma were left to propagate fresh growth.

Professor BYERS was very pessimistic with regard to the treatment of malignant tumours of the breast; he had only seen two cures in the course of twenty years' practice. He thought the knife was the best treatment, but a very poor best; we should have to learn more about cancer before we could learn to treat it successfully.

Dr. KEVIN, speaking as a general practitioner, said he generally found recurrences in eighteen months. Dr. Byers had proclaimed himself a Jeremiah, and he (Dr. Kevin) was Jeremiah II.

Dr. ROBERT CAMPBELL, F.R.C.S., agreed with Dr. Mitchell in always removing the pectoralis major, in order that he might clear away the lymphatic glands.

Sir WM. WHITLA said that when house-surgeon in the Royal Hospital, Belfast, he had traced a number of cases treated by old methods, and all had died in years.

Dr. MITCHELL briefly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FEBRUARY 5TH, 1904.

The President, DR. ALFRED SMITH, in the Chair.

DR. ALFRED SMITH showed a uterus removed by panhysterectomy containing a large senile polypus.

Dr. E. H. TWEEDY showed two dermoids, and one cancerous ovary removed by abdominal section.

The adjourned discussion on Dr. Purefoy's report of the Rotunda Hospital for the year 1902-03 then took place. Drs. Tweedy, Jellett, Wilson, FitzGibbon, Fitzgerald and the President spoke, and Dr. PUREFOY replied.

The meeting then adjourned.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 15th, 1904.

AT the Society for innere Medizin Hr. Albu showed

PREPARATIONS FROM THE INTESTINAL TRACT.

The first was a traction diverticulum of the duodenum. The patient was a man who suffered from violent pain in the upper part of the abdomen and obstinate constipation. An ulcer of the duodenum and stenosis of the pylorus were diagnosed. An operation was performed, at which it was ascertained that the pylorus would admit a finger. Behind the pylorus was a hard mass—peritonitic bands. Gastro-enterostomy was performed, but the man died some days afterwards of pneumonia. The autopsy revealed an ulcer in front of the pylorus; by the peritonitic bands the duodenum was dragged forwards, and in this way a diverticulum had been formed.

The second was an invaginated tumour of the small intestine. The patient, a man, æt. 53, who had always been healthy previously, suffered acute pain in the abdomen for four or five days—with diarrhœa. Palpation revealed a movable tumour in the right side. There was dulness above the tumour, which disappeared, however, on inflation. The patient was transferred to the surgical klinik, where high fever set in, and an abscess developed in the right side, from which pus escaped after incision. The patient died shortly afterwards. A tumour of the small intestine was then found, a fibro-adenoma, which had undergone necrosis at the circumference, and which had then led to suppuration.

The third was a case of cancer of the pylorus, originating in an ulcer. The patient, a man, æt. 30, was supposed to be suffering from pernicious anæmia. On examining the blood, however, nothing appeared to justify this diagnosis, and Hr. Albu suspected cancer of the stomach to be the cause of the anæmia. Opposed to this, however, was the fact that no motor insufficiency could be detected in the stomach. After a fortnight paralysis of the left facial nerve and of the left upper extremity came on, which improved to some extent in the course of a few days. Shortly afterwards the patient died. The autopsy showed cancer of the pylorus that had developed on the base of an ulcer. The suspicion of cancer was therefore justified, although there had been no motor insufficiency. No clot was discoverable in the brain as the cause of the hemiplegia, but hydrocephalus internus and a diffuse fibrous arachnitis.

The fourth case was one of carcinomatous ulcer of the pylorus, not deep, but rather superficial. The patient, a woman, æt. 63, had never been ill, and had no pain in the stomach, nor hæmatemesis. The microscope showed that the carcinoma had developed out of an ulcer.

Hr. Litten remarked on the third case with hemiplegia, that he had observed a similar case in which hemiplegia was associated with carcinoma of the pylorus. The brain was afterwards examined most carefully, and slight cancerous metastases, that might easily have been overlooked, were found to have affected the ganglia.

EXPERIMENTS WITH FLUORESCING SUBSTANCES.

Professor Tappeiner and Dr. Jesioneh related some experiments they had made on the subject in a recent number of the *Münch. med. Wochensch.* It had been shown that fluorescing substances, eosin, fluorescin, acridine, and quinine, among others, even when diluted to a millionth part, had a destructive power over low organisms, such as the ciliated epithelium of the frog, and that they had the property of destroying the power of enzymes and toxins. The authors named were led, therefore, to try if these substances had any therapeutic properties. They painted diseased portions of skin with a 5 per cent. aqueous solution of eosin and then exposed the part for a long time to sunlight or the light from an arc lamp. Three cases of carcinoma of the skin so treated showed striking improvement after sixty, fifty, and thirty days respectively. A similar beneficial effect was produced in a case of tubercle of the testis in a boy, æt. 14, who had also scrofulous ulcers on the scrotum; here the eosin solution only was injected. In lupus the specific tissues disappeared under the influence of the eosin and light treatment. Condylomata on the female genitals also disappeared in ten days, and likewise a primary lesion of the tongue. Here the regionary secondary swellings also disappeared. A case of primary genital lesion with inguinal scleradenitis

also promptly disappeared, but sixteen weeks later there was a sparse roseola on the abdomen.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, February 14th, 1904.

The Theory of Hearing.

At the Gesellschaft der Aerzte, Exner and Pollak gave an exhaustive paper between them on the theory of hearing. The sum and substance of their arguments was a faithful adhesion to Helmholz's original idea, or the resonating theory, *i.e.*, when a tuning-fork is set in motion the outside sound comprehends one-half of the sound, but, if a resonator be conducted from between the prongs, a double or complete wave of the tuning-fork will be obtained.

The necessary irritation to produce hearing at all was modified by physiological and anatomical construction differing in some measure from the other senses, such as taste and smell, which were more chemical in action, and depending upon the moisture of the mucous membrane involved in the physiological transformation.

The sensation of feeling was purely mechanical, while sight depended on a photochemic action.

In the ear we have two senses so closely related that it becomes difficult to separate the one from the other, *viz.*, static and auric, which are probably both mechanical in origin, depending on the wave transmission of vibrating molecules of air, whose movements are delicately conveyed by intermediate organs to the fibre of Corti, which has a basal membrane, and, having different lengths, is suited to receive wave sounds varying from 33 per second to 4,000 in the same time. They seriously assure us that this theory has been assailed of late with an intermediate theory of intermission.

Besunning the Throat.

At the meeting of the Innere Medizin Association, Sorgo showed a case in which he had treated a tuberculous growth in the throat with reflected sun's rays with perfect success. The neoplasm was about the size of a large pea. The treatment was intermittent, owing to persistent vomiting, that seriously delayed any methodical application of the treatment.

Schrötter remarked that this idea of Sorgo's was not a new one, and had been in practice at the Third Imperial clinic for a long time past; but, owing to some delay in the preparation of particular apparatus, the treatment had been somewhat suspended, although the results so far obtained had been favourable in many cases; but it must be admitted that this therapy of the bacilli is not all that could be desired. In many cases the tubercle will disappear entirely, but in others it will persist in spite of the most heroic treatment, more especially in such cases where the neoplasm seems to shrink and almost disappear. Such cases cannot be assumed to be cured either locally or generally, although the growth has been very much reduced, while the source and general nucleus lies still active and undisturbed. It must be admitted that this is a temporary expedient in many cases, and not a cure.

Elevated Climates.

Sucke gave a theoretical explanation of elevated situation on disease, and attributed the successful treatment of tubercle, &c., to the high radio-activity of the sun's rays. After long and laborious observations he finds that the emanations are five or six times as great at 5,900 ft. above sea level as it is on the seashore. The potentiality is equal to the difference of tension between the positive air and negative earth. Thus the human tissues are acted on after Becquerel's theory in proportion to the surroundings.

Variation of Temperature in Insects.

Bachmetjew, Professor of Physics at Sofia, has recently added to our knowledge the astonishingly wide variation of temperature that prevails in the insect order of life. In the Tropics, where the air is very dry and the heat intense, the hydrocatitharis beetle, according to Girard, exists in wells of an enormous temperature. Cantoni has fed the caterpillar of the Bombyx mori at a temperature of 47° C., or 112·6° F., without the slightest injury to the insect. On the other hand, different insects and caterpillars are found in glaciers without having suffered in any way. Again, the eggs of the Bombyx rubri have been treated to temperatures varying from 39° C. to 59° C., or from 70° to 122° F., without being disturbed in their activity, which must be accepted as an interesting biological experiment to know that this insect can be cultivated at different temperatures than the geographical positions at present assigned to them. In discussing the accommodation of these insects, Bachmetjew attributes the power of resistance to the condition of the air and moisture of the insect. At ordinary temperature the insect remains undisturbed; but a rise to 37° C., or 98° F., will increase the moisture and body heat in proportion to an unbearable extent; but to overcome this the insect throws off a large quantity of its moisture, thus reducing the body temperature to something like 15° below the temperature that would be attained if it had not gone through that transformation. These changes are accomplished through the skin and body, and the usual pulmonary apparatus of the insect.

The vital maximum temperature, therefore, ranges between 45° and 54° C., or 113° and 129° F. The vital minimum is placed at 8° to 10° C., which is the lowest temperature the fluids of the insects are able to resist before the critical or freezing point, when death takes place.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

CHATEL-GUYON.

The Thermal Station of Châtel-Guyon is situated in the department of Puy-de-Dôme (part of the old province of Auvergne), France. It is accessible from Paris by the Paris-Lyon-Mediterranée Railway, *viâ* St. Germain-des-Fosses and Clermont-Ferrand. The nearest railroad station is Riom, seven hours' rail from Paris and half an hour carriage drive from Châtel-Guyon. There are several excellent trains from Paris each day, and a good omnibus service from Riom.

At Châtel-Guyon are two bath establishments, both belonging to the same company and under one management. The two establishments include excellent hydropathic arrangements of high merit and of wide variety. The new one ranks among the best of modern European hydropathics. It is especially notable for its excellent and special appliances for vaginal injections, "washings-out" of the stomach, and for general intestinal lavages. The electro-therapeutic department has also peculiar adaptations for electric baths, as also its mecano-therapic annexe for the active gymnastic treatment of the abdominal muscles.

Châtel-Guyon lies on a slope of the Dôme mountains at 1,200 feet altitude; its mineral waters descend underground from high levels, finding their way to the surface (partially through natural fissures in the rocks

and partly by borings) at temperatures varying from 75° to 101° Fahrenheit.

There are here twenty-seven mineral spirngs, with a combined flow exceeding three million litres every twenty-four hours. This enormous quantity makes Châtel-Guyon one of the most important Spas of the world, as the mineral waters are not only great in quantity, but also of high excellence in quality.

The most celebrated spring, Source Gubler, shows, by analysis of Dr. Magnier :—

Gaz acide carbonique libre	1·1120
Chlorure de magnésium	1·5630
Chlorure de soude	1·6330
Bicarbonate de chaux	2·1796
Bicarbonate de fer	0·0685
Bicarbonate de lithine	0·0194
Bicarbonate de potasse	0·2583
Bicarbonate de soude	0·9550
Sulfate de chaux	0·4990
Silice	0·1108
Arsenic	Traces
Acide phosphorique	Traces
Acide borique..	Traces
Alumine	Traces
Total	8·3986

The Châtel-Guyon waters are used both internally and for bathing. The baths are given with running water, coming directly from the springs, and so having all advantages of natural temperatures and combinations. They stimulate the skin functions and promote circulation. The first sensation in the baths is one of coolness, but in a few minutes the body is covered with gas-bubbles, and heat is produced. On emerging from the bath the body is red, the blood rushes to the skin, and there follows a decongestion of the internal organs. This beneficial effect aids and increases the decongesting action which had been produced internally by drinking the waters.

Owing to the constant running of the water while in the bath its theraputic action is maintained during the whole period of immersion, and, because of the different temperatures of the springs, baths can be given varying from 75° to 95° F. without any artificial heat.

The good effects from drinking and bathing can be further extended at the physician's pleasure by adding local applications and internal irrigations.

The chief indications for a course of treatment at Châtel-Guyon are obesity, constipation, dyspepsia, enteritis, appendicitis, congestion of the liver and spleen, diseases of the kidneys, ovaries, uterus, &c.

Châtel-Guyon has during the summer season a very competent medical staff, including English-speaking physicians. It has also good hotels, pensions, villas, and furnished apartments. Prominent amongst the hotels are the Splendide and Nouvel (succursales of the well-known Hôtel Mirabeau, of Paris), which occupy a beautiful situation in the park of the thermal establishment, and have all modern comforts. The large park also includes the baths, buvettes, music kiosques, casino, covered promenade, and gymnasiums.

Around the isolated hill on which Châtel-Guyon stands are many interesting excursions near and far. The old town of Riom, and various ancient châteaux, are within thirty minutes' drive, and also comparatively near are the city of Clermont-Ferrand and the adjoining fashionable town of Royat. The whole Auvergne district is one of the most attractive in all France, attractive alike to archæologist, antiquarian, curiosity-seekers, and lovers of the picturesque. Those fond of delicacies would likewise be gratified by visits to the popular preserved-fruit factory of Vieillard, in Rue Pascal at Clermont-Ferrand, and to the unique chocolaterie of Rouzaud-Bouchet, at Royat.

Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

OPERATIONS FOR FISTULA IN ANO.—Mr. MAYO COLLIER operated on two cases of fistula *in ano*, one of which, he pointed out, was of exceptional interest. The patient was a man, æt. 55, who had suffered some years before from some affection of the rectum, the nature of which apparently could not be clearly made out. He had suffered from pain and difficulty in defæcation for some weeks. This was followed by an abscess outside the rectum, which burst in the ischio-rectal fossa ; subsequently to this, his condition mended for a time, but this was again followed by a recrudescence of pain and discomfort, succeeded by a second abscess, which burst in the opposite ischio-rectal fossa. No history of syphilis could be elicited, nor could history of bladder or prostatic affection be made out. The family history was good, and, apparently, there had been no tubercle in any members of his family. The lungs and heart were seemingly sound, and there was no albumin in the water. On examination, the whole perinæum was found to be riddled with sinuses and marked with scars and unhealthy-looking tissue as far as the tuberosities of the ischia. The prostate could be felt apparently normal, and there was nothing abnormal within the rectum excepting evidence of a hard fibrous stricture at the upper margin of the internal sphincter. It was curious, Mr. Collier thought, to note, in association with this stricture, that at no time had there been difficulty of defæcation, nor had the word stricture, so far as the patient remembered, ever been mentioned to him. Again, Mr. Collier pointed out, none of the external sinuses led into the bowel above the stricture, nor, as far as could be made out, was there evidence of these sinuses having at any time communicated with the rectum, the coats of the bowel above the stricture feeling quite normal to the touch. On probing the sinuses, it was found that they extended up into the pelvis as far as the division of the pelvic fascia at the white line ; the levator ani muscle was perforated and partly destroyed, and the lower half of the rectum was apparently completely denuded. Other sinuses led outwards, burrowing beneath the skin and denuding the deep fascia for several inches. The whole lower pelvic cavity was seemingly riddled with abscess burrows. Mr. Collier said that no hope of cure could be entertained unless the stricture of the rectum could be completely divided and the parts set at rest. Mr. Collier, therefore, having passed his finger into the rectum above the stricture, divided all the tissues backwards to the coccyx, thus laying the internal and external sphincters completely open. The other sinuses were carefully investigated and curetted, and the undermined skin laid open. Strips of gauze soaked in tincture of iodine were packed into the recesses, and the wound in the rectum plugged with strips of iodoform gauze. Mr. Collier said that this was a most interesting case, and although there was apparently a complete absence of history of syphilis, yet the stricture associated with the course of the disease could only be explained by a specific infiltration of the outer wall of the rectum leading to gumma and the usual breaking down of the new tissue.

The second case was that of a man, æt. 45, which illustrated, Mr. Collier pointed out, the relationship of tuberculous disease of the lung to fistula *in ano*. This association, he said, had been recognised and well understood for many years, and, indeed, in the early days of surgery the student was taught that the fistula *in ano* acted in the same way as a safety valve to the

tubercle, and prevented its rapid extension. In this case, Mr. Collier remarked, there was marked thickening of the tissues immediately adjacent to the rectum in the ischio-rectal fossa. The external sinus was found to communicate with the cavity of the rectum, and there was some burrowing forwards and backwards. The parts were laid open, the sinus well scraped and packed with gauze soaked in iodoform emulsion. Mr. Collier anticipated in this case a satisfactory recovery. The two cases, he thought, were interesting as illustrating the causation of fistula *in ano* from two distinct points of view.

THE TREATMENT OF CANCER.

The victories of modern medical science are being won with a swiftness and a completeness that are simply amazing. The introduction of aseptic surgery alone has probably achieved more for the advance of the art of healing and the benefit of humanity than the united labours of all previous workers in the same field. There nevertheless remains a wide territory yet to be conquered. Take the case of cancer, using that term in a broad sense to include malignant growths generally. The origin of that terrible and apparently increasing scourge of mankind remains a profound mystery, just as its treatment is for the most part hopeless and discouraging. For all that, there are many signs of the times that this most elusive foe is being gradually out-manœuvred. In considering the position with regard to cancerous maladies it is reassuring to recall the course of events with regard to a disease that hardly a generation ago was no less mysterious, and but little less disastrous and hopeless when once established—namely, tuberculosis. To-day phthisis is read like an open book, and its prevention, treatment, and cure are carried out with the precision and success that are begotten of knowledge and experience. There is no particular reason, so far as can be seen, why scientific medicine should not one day unravel the secrets of malignant growths as she has done in the case of tuberculosis. But meanwhile, as we have said, our knowledge, full and adequate, is yet to come. Bacteriology, which furnishes the key to tuberculosis, has hitherto been appealed to in vain as regards malignant neoplasms. Many persons have fondly hoped they have found a specific "cancer" micro-organism, but no such discovery has stood the test of experience. One of the most recent claims of the kind was that of Dr. Otto Schmidt, of Cologne, who devised a method of immunising treatment by serum obtained from a "pure culture" of a specific organism alleged to have been isolated. Dr. Schmidt, it is to be feared, has persuaded himself into an untenable position. Dr. John Shaw, the well-known London physician, has personally investigated the matter and has published his observations and conclusions in a fair and judicial pamphlet. A more crushing exposure of pseudo-scientific fallacy parading in the garb of responsible medical wisdom could hardly be imagined. Dr. Jossé Johnson, in communicating the pith of Dr. Schmidt's conclusions to the Abernethian Society (*a*) observed that "Dr. Schmidt isolated one single parasitic cell, and by artificial cultivation under varying conditions of light, air, moisture, and warmth produced all the other forms from it." The lavish variety of the descendants of that "single" organism may be gathered from Dr. Shaw's account. He was shown a pure culture of an alleged parasite from melanotic sarcoma under the microscope. His astonished eye was presented with a field of granules varying in size from that of a red blood corpuscle to that of a gonococcus. Another "pure culture" from an epithelioma of the breast showed similar variations in size of granules. It appears that Dr. Schmidt has abandoned injections of serum in favour of increasing doses of sterilised cultures. Dr. Shaw examined various patients said to have been benefited by the treatment. In one case a woman was going home with the cancerous process "perfectly cured," but he found that the tumour on her forehead was about one-third larger than when seen a few weeks previously. An English medical man under treatment was said to have improved markedly, but Dr. Shaw found serious extension of the growth. This case we have ourselves examined and can certify that there is no appearance of arrest of the malady. In short no medical man should countenance a visit on the part of a patient to Dr. Schmidt unless he has first carefully read Dr. Shaw's pamphlet. Of other new forms of treatment, notably the focus tube, the high frequency current and last, and most wonderful agent of all, radium, we cannot as yet speak more than hopefully. It is clear, however, that in certain cases we are able to modify profoundly the progress of carcinomata and sarcomata. The curative influence of the X-ray tube upon secondary enlargement of glands and recurrent nodules is definite, as well as upon ulcerating surfaces. The high frequency current appears to have cured some accessible sarcomata and it certainly removes

(*a*) *Lancet*, November 14th, 1903.

the pain of cancer and arrests other symptoms in a remarkable way. The most promising agent, however, is radium, which may now be regarded as having curative powers over rodent ulcer, and over epitheliomata if not of too old standing. It is safe to predict that radium will be the object of universal investigation in the immediate future. Hitherto the surgeon has failed in his attempts to arrest the progress of cancer when it has once gained a footing in the human body. Here and there he may appear to gain an isolated success, but in the vast majority of cases he is powerless. It is to the discovery of a trustworthy therapeutic remedy that the hopes of scientific medicine must naturally turn. Has that much-desired specific agency been placed in our hands by the discovery of radium ?

THE TEACHING OF HYGIENE.

RECENT researches into the problems of disease have gone far to secure evidence of the scientific truth that "prevention is better than cure." Already the life work of many medical men is being definitely directed to prophylaxis, and the admirable work accomplished by our medical officers of health has amply demonstrated the value of a scientifically directed service of public health. The slow-moving mind of the general public has realised something of the advantages arising from improved sanitation and the enforcement of measures for the protection of the physical welfare of the Commonwealth. The "healer," it may be hoped, will always be treated with respect and accorded sympathetic support, but it is well that the "teacher" of sanitation should be accorded a status meet for the important responsibilities and duties which devolve upon him, and we believe the medical man of the future will render service chiefly as an adviser in all matters pertaining to the preservation of health and the prevention of disease, rather than by a mere practice of the apothecary's art. We are glad to find, therefore, that medical practitioners throughout the country are supporting the very influential petition which is to be presented to the central educational authorities of the Kingdom, urging upon them the necessity of providing compulsory teaching of hygiene in all public elementary and secondary schools. We understand that already more than fourteen thousand signatures have been appended to this remarkable and most representative appeal of the registered medical men of Great Britain. It is likely that such a document will do much, not only to influence our educational authorities, but also to draw public attention to the functions of the physician. For too long the practitioner has been willing to follow rather than insisted on his right to lead. In all that pertains to the health of the people the medical man should play the part of the pioneer. In the document to which we have referred special reference is made to the necessity of imparting trustworthy information to the scholars of our public schools concerning the dangers arising from the abuse of alcohol. The widespead prevalence of alcoholism among our people and the growing addiction of women to a dangerous indulgence which is threatening the race with serious deterioration make such a step most desirable. Apathy, ignorance and, we venture to add, a fanaticism born of misconception and partial knowledge, have done much to make us "a drunken nation." If intemperance is to be arrested it must be by a scientifically controlled effort to secure sound education in the principles and practice of hygiene, of which, of course, temperance should form an important part. It is to be hoped that medical men throughout the country will not rest satisfied with a mere approval of such action as is proposed, but will afford active support, and we hope the day is not far distant when in connection with every school throughout the country there shall be a thoroughly qualified medical man or medical woman who shall be responsible for the well-being of the scholars and shall act as adviser in all that pertains to the hygienic condition of the school.

THE CENTRAL MIDWIVES BOARD AND IRISH MATERNITY HOSPITALS.

WE print in another column a letter from the Master of the Rotunda Hospital to the Secretary of the Central Midwives Board regarding the position which Irish trained nurses occupy under the new Act, and the Board's reply thereto. The resolution adopted by the Board will, we fear, prove incomprehensible to the ordinary individual. It reads as follows :—"That, having considered the letter addressed to them by the Master of the Rotunda Hospital, the Board regret that the suggested alterations were not brought to their knowledge before the Rules were sent to the Privy Council, as having been now approved by that Body, it is impossible for the Board to alter them." We presume the Board meant this resolution to convey some meaning, but we confess that we are unable to even guess what it is. The Board say that the Master of the Rotunda Hospital should have brought the conditions under which nurses are trained at the Rotunda Hospital to their notice before the draft copy of rules recommended by the Board was submitted to the Privy Council. We venture to ask the Board at what exact stage of their proceedings could the Master of the Rotunda Hospital have taken this step. Did the Board invite suggestions or seek information from the heads of lying-in hospitals before drawing up their rules ? The account which has gone out to the public, be it a correct one or not, we do not know, is very different. It is that the Board after its appointment had many stormy meetings *in camerâ*. That these meetings resulted in the drawing up of a majority and of a minority report. That the majority report was one which was not consonant with the assumed object with which the Act was passed and that it, in fact, proposed rules which would not have conduced to the improvement of the present type of midwife. That the Privy Council refused to sanction the majority report and sent the draft rules back to the Board in a form which adopted many of the points on

which the minority report insisted. That all these proceedings were regarded as confidential, and that not until the Rules had been approved by the Privy Council were they allowed to see the light of day. If this was so, the question naturally arises, When should the Master of the Rotunda Hospital and the heads of other Irish maternity hospitals have brought to the notice of the Board the "suggested alterations" in the rules. Perhaps the Board will suggest an answer. There were two occasions on which the authorities of the Rotunda Hospital were able to make representations on behalf of their training school. One was during the passage of the Act through Parliament, the other was when the Rules were made public. Representations were made on both occasions. On the first occasion, these authorities were informed that nothing in the Act would prove prejudicial to the Rotunda nursing school, and that the promoters of the Act recognised that that institution was deserving of support. On the second occasion—the present one—they are informed that the Board is sorry, but that they cannot admit Rotunda trained nurses to their examination. We have read Mr. Heywood Johnstone's letters to the Royal College of Physicians of Ireland, at the time of the introduction of the several Midwives Bills, letters in which he gave a definite guarantee that the Bill, if passed, would in no way interfere with the Chartered Irish Maternity Hospitals, as he was "well aware of the good work they had done." Mr. Heywood Johnstone is a member of the Central Midwives Board, and that body has unanimously adopted the resolution given above. We presume that Mr. Heywood Johnstone did not attend the meeting at which the resolution was adopted, but he must have known that Dr. Tweedy's letter was to come before the Board, and to our mind he should have been in attendance to support his pledge. The resolution, however, conveys one item of information that may prove of value. It conveys the fact that the Board "regret" that their ignorance of the course of training for midwives considered advisable by the great maternity hospitals led to the drawing up of rules which excluded the nurses trained in the largest of these hospitals. If the regrets of the Board are not a mere *façon de parler*, we presume that they will be willing to support the application which we understand the Irish hospitals are about to make to the Privy Council. If they refuse to support such an application, their action will, we fear, be added to the list of broken pledges with which, rightly or wrongly, many Irishmen associate English rule in Ireland.

Notes on Current Topics.

The Health of the Emperor of Germany.

The accounts of the health of the Emperor of Germany are, to say the least of it, not reassuring. When the operation on the throat was announced some time ago, alone of the medical journals in this country The Medical Press and Circular raised a note of warning as to premature conclusions about the real nature and gravity of the Kaiser's illness. In the face of the detailed microscopical report and the emphatic statements of other medical journals, both in this and other countries, it required some courage to adopt that attitude. It is difficult to understand how a responsible medical editor could countenance the publication of positive assertions of the innocency of a particular malady upon the strength of bulletins and reports published under strict official censorship. A report given at the present moment by an unimpeachable medical authority would be of far greater value than that given at the time of the operation. It is to be hoped that such an authoritative statement will be shortly forthcoming and that it will reassure the sympathising world that exists outside Germany.

Epilepsy and Genius.

The belief that insanity and genius are so closely interdependent as to be regarded by some as all but synonymous is one which was largely shared by the older psychologists. Genius—the *ne plus ultra* of intellectual activity—is, in reality, the highest expression of nervousness, using the word not as it is usually interpreted, but to indicate the most highly exalted condition of nervous organisation of which the human mind has shown itself to be capable. It is its very perfection, in fact, which tends irrevocably towards its ultimate deterioration. The seeds of decay are inherent in the most luxurious bloom of intellect. "Le génie," according to Lamartine, "porte en lui une principe de déstruction, de mort, *de folie*, comme le fruit porte le ver." The truth of the Aristotelian maxim, "Nullum magnum ingenium sine mixtura dementiæ," is abundantly verified by everyday observation, for it is the exact expression of a modern psychological doctrine. Of all mental disorders accompanying genius, epilepsy is the one the occurrence of which perhaps surprises us most in this connection. It can be readily understood that acute mania, for instance, might result from mental strain, leaving the patient but little damaged after recovery, but, knowing the mental obtuseness and deterioration so often seen in those of epileptic tendency or heritage, it is more difficult to realise that any good mental work can be achieved by such. Yet there are many well-known instances of epileptics who were men of real power and genius. Julius Cæsar, Mahomet, and Napoleon are each supposed to have been subject to epileptic fits. A far greater number, of course, of statesmen, poets, musicians, and scientists are included in the "glorious group of madmen" who have enriched our knowledge, and left behind them the indelible imprints of their noble intellects. In common with some epileptics, they were all men of highly-strung nervous systems possessing refinements of thought and reasoning unknown to minds of more sober but less active mental organisation. As in some over-ripe fruit the more subtle and delicate aromatic flavours appear, so in the mind which is over-developed in certain directions are peculiarities and eccentricities, often the precursors or associates of true

epilepsy, prone to manifest themselves. Epilepsy in early life is generally regarded as fatal to the subsequent mental development of the individual, but all who are epileptics in childhood and who outgrow the disease do not deteriorate; on the contrary, many show distinct evidences of intellectual superiority, "perilous" though this may sometimes be. The recognition of these facts has led to a great change in the manner in which this form of mental disorder is regarded and also in the various modes of treatment adopted for its relief or cure. The value of psychical influences, of an adequate amount of rest and nourishment, of exercise, and of genial surroundings are becoming more generally appreciated in this as in other diseases of the mind. As an evidence of mental degeneration it must still remain, but in consideration of its relationship to some of the highest grades of mental activity it will not bear the social stigma to such an extent as other forms of alienation.

The Regius Professorship at Oxford.

A GOOD deal of feeling has been aroused by the recommendation made to the Prime Minister to fill the Regius Professorship of Medicine at Oxford, vacant through the resignation of Sir John Burden Sanderson, by the appointment of the present Reader in Pathology. An important meeting of Oxford medical graduates took place under the presidency of Sir William Church and protested strongly on public grounds against thus handing the Professorship over to a specialist in one branch of medicine. There has been no attempt at introducing personalities into the contest, and it is known that Dr. Ritchie, the Reader in Pathology, has made himself a *persona grata* to all his colleagues since he came south. The plea put forward on behalf of his appointment is one of economy, that the funds of the University would be relieved of a strain if the Readership could be merged into the Professorship, and, moreover, it has been urged that no Oxford medical graduate of the position and parts necessary to make an ornamental and useful Professor would be forthcoming to fill the chair. The Regius Professorships at Oxford and Cambridge are ancient and dignified offices, and the holders of them are something more than mere provincial physicians. They emphatically embody, or should embody, all that is modern in progress of the day with all that is sound in the learning of the ancients, and their position is one that commands the ear of the whole medical world. There has never been any difficulty in getting a Regius Professor of high learning and wide culture at Cambridge, but a few years ago, when Sir George Humphry died, the University could not get a suitable candidate at the time to fill his chair. The Professorship of Surgery, however, is not a royal one, and is of quite modern origin, being created, in fact, for Sir George Humphry, when he resigned the Professorship of Anatomy in 1888. In that case the University appointed a competent Reader to give the lectures, and waited The wisdom of this course has recently been demonstrated by the happy induction of Mr. Howard Marsh into the chair. If it really be the case—which seems open to grave doubt—that no Oxford graduate of sufficient eminence will come forward at the moment, Oxford might imitate the example of her sister University, and bide her time. There are many erudite and cultured physicians who would welcome the learned leisure of the Isis as a relief from the turmoil and buzz of practice.

State Medicine in Russia.

OUR hygienic reformers are wont to complain of the difficulties that surround them, and of the inertia of the legislative machine when they strive to put it in motion. Local authorities are obstinate and short-sighted, and members of Parliament are complacently indifferent. In Russia, however, indifference is not displayed by the Government, and obstructive measures are not in favour. The political advisers of the Czar keep a very vigilant eye on most things that are going on, and if they do not approve of the trend they are taking, they have sharp and incisive methods of dealing with objectors. In their scheme the passive resister has no place. At the recent National Congress of Medical Men resolutions were submitted on various subjects urging reform and progress, especially in the education of the peasants. These resolutions pointed out that it was hopeless to expect intelligent co-operation in hygienic reforms from a proletariat little better than the lower animals in their knowledge and intelligence. An official intimation was conveyed to Dr. Rostovtseff that the resolutions were not pleasing to his Majesty's advisers, and that they had better be dropped. The Congress was loth to have its views set at naught, and demanded that the resolutions should be read and put. This the President declined to do—and for his sake it is perhaps as well that he did not—and he proceeded to declare the sittings ended. His action created considerable indignation, and the murmers of the members were drowned by the music of a military band. "A tumult then arose and loud protests were made. As if by magic policemen appeared in the midst of the angry doctors, and they were dispersed by the gentle methods that the Russian gendarmerie acquire by long practice. Numerous arrests were made." After this, one feels that though we have our obstructions to remove over here, our brethren in the Czar's country have their own special difficulties—to which ours are mere child's play. The part of sanitary reformer is not likely to become really popular amongst Russian medical men while it is mounted on a stage controlled by a brutal police and backed by a desolate prospect of Siberia.

Boasting Extraordinary.

It has often been maintained by THE MEDICAL PRESS AND CIRCULAR that every medical man, who is at all qualified for it and can spare the necessary time, should enter in some way or other into the public life of his district. Much of the

neglect and misunderstanding from which the profession suffer is due to the onerous nature of its work, which denies its members the chance of championing its own interests and the interests of the public health from positions of authority. Even when considerable sacrifice of personal ease and recreation is entailed, it is well worth while for the medical practitioner to sit on public bodies, if not for his own benefit at least for that of the profession and the community. In the report of a mayoral banquet recently held, we regret to note that the mayor, himself a medical man, seems to have employed the occasion offered him by his speech to denounce Koch's "treatment" for tuberculosis, and to boast what he would do if Mr. Rockefeller would provide him with a bacteriological laboratory. The mayor appears not to have any particular skill in laboratory research himself, and his grasp of the principles of Koch's "treatment" seems to be more forcible than discriminating. The tubercle bacillus seeks, according to the mayor, to kill his offspring by overcrowding, while he (the mayor) would kill them by inoculating stronger ones that would speedily overpower them. The report of the speech does not indicate the result on the patient himself; if he cannot resist the puny tubercle bacillus, it seems difficult to understand how he could survive the "infinitely more powerful" bacilli that the mayor would provide. Perhaps, however, a patient would not be needed, as, if the mayor were only presented with a laboratory, "he would speedily convince the world of the truth of his statements." We are all anxious that research into scientific problems may be pushed by every proper means, but this sort of Thrasonical magniloquence is more likely to hinder than to help the cause we have at heart. The moral of this Dartmouth oration is that medical men should not air purely personal and unproved theories in public; there is plenty of solid and established fact available for after-dinner purposes.

The Japanese Medical Services.

Whilst all eyes are turned to the East watching our sturdy little ally engaged in a life and death struggle with a mighty European power, the medical man will feel a peculiar interest in the arrangements made for the care and treatment of the victims of the contest. As a straw shows which way the current is flowing so does efficiency in the secondary or auxiliary services demonstrate preparedness in the primary ones. The first object of an army or navy is to become an efficient fighting machine, to which end, of course, must be subordinated all purely humanitarian considerations. But no sound, well-administered army or navy can afford to neglect its medical service. The disregard shown for generations to the medical establishment of our own Army is now seen to be only a part of the general *laissez aller* policy that governed the whole of the War Office system. That, it is hoped, is now in course of being righted. With Japan it is different. "Happy is the nation that has no history," and Japan can claim to be making history without being hampered by pedantic precedents or effete regulations. She has built up a first-rate fleet and a first-rate army, and every detail of their organisation and equipment has been worked out with a thoroughness and an expedition that are wholly admirable. Perhaps the greatest testimonial to their efficiency is that their medical services fall not a whit below the general level of excellence. The pathetic incident of an admiral signalling a request for lint after an action, as happened in the Spanish-American war, is not likely to be repeated, from the Japanese side at all events. The pattern on which the medical service is organised is that which many of our reformers have contended for for years. Each unit of each arm of the service has its own medical staff—and a very complete one, too—which forms an integral part of equipment. A most important point is that the medical department has its own transport, and is therefore not dependent on the goodwill of the commissariat corps. As wastage occurs in the ranks and men are moved to hospital, a proportionate part of the medical staff goes with them, so that the ratio between the officers serving in the field and the officers serving in hospital varies according to the demands for each. The discretionary powers left in the hands of the executive in the field are very large, and references to headquarters are reduced to a minimum. If a medical military *attaché* were to accompany the Japanese army, there is little doubt but that he could supply our War Office mandarins with some information that would be better for the rank and file of the Army than for their own dignity.

Universal Training and National Physique.

It is stated that "the most important topic which can exercise the mind and the intelligence of anyone dealing with racial phenomena" is the question of our alleged physical deterioration as a nation. The Royal Commission appointed to deal with this matter is now busily engaged in receiving evidence on one side or the other from those who are in a position to give authoritative opinions upon the subject. Whether or not the adoption of a system of universal service—a modified form of conscription, so to speak—would be the best means for improving our national physique and rendering the citizens of our Empire thoroughly fit to defend their hearths and homes is a question which may well occupy the minds of statesmen and sanitarians alike. In the current number of the *National Service Journal*, the official organ of the National Service League, Lieut.-Colonel W. Hill Climo, M.D., points out that, as a preparation for such service, special attention is required at the three critical periods of infancy, childhood, and adolescence. Stress is laid, and rightly so, upon maternal responsibility as being capable of influencing materially the national physique for good or evil. Among the classes from which recruits are drawn it is, unfortunately, only too true that the women are "singularly ignorant of the duties of maternity." In more senses than one, the physical life of man is fashioned in the cradle. The returns of the

Inspector-General of Recruiting, of which mention has already been made in our columns, show plainly that there is a considerable increase in the percentage rejected for various ailments. The introduction of some system of universal service, whether purely military or partaking more of the nature of a compulsory course of physical training at school or college, would go far towards counteracting the unhealthy influences now at work upon our national physique.

The Ocular Basis of Migraine.

MUCH has been written lately with regard to the part played by eye-strain in the production of many physical evils, chiefly of the nervous system, especially in those who follow literary or other occupations necessitating the habitual accommodation of the eyes. Dr. George M. Gould (*a*), of Philadelphia, the chief exponent of this modern theory, believes that migraine may be similarly caused, and that the use of the eyes at near range is at the root of this distressing affection in the great majority of cases. The disease is one which renders the life of the sufferer therefrom well nigh intolerable while it lasts, and its victims live in perpetual dread of the next attack. It is hardly to be wondered that such individuals will fly at anything which they think will relieve their symptoms, but, strangely enough, the condition of their eyes is the last thing to which attention is drawn. The interval between the attacks is only too often spent in a round of social excitement, in travel, or in closer application to their work. It is noteworthy, too, that the affection is more common in those of finely strung nervous organisations and those who are capable of getting through an immense amount of mental work. As the French say, "La migraine est le mal des beaux esprits." The cases are, therefore, seen more frequently in private than in hospital practice. Dr. Gould states that the condition may be produced experimentally by wearing misappropriate glasses, and he is convinced that some error of refraction will generally be found in these patients if it be looked for. On account of the association of vomiting and gastric disturbances, it is very generally believed that the source of the trouble lies in the liver or stomach, but in how many cases has it not been observed that the treatment of these disorders after the most approved fashion has failed to prevent the recurrence of the malady? The ocular theory of migraine is one which deserves the weightiest consideration of every practitioner under whose care the patient happens to be.

Traumatism and Phthisis.

THE ready ingress of the ubiquitous tubercle bacillus into any part of the body whose tissues have been damaged by injury and their resisting power to infection consequently lowered is one of the commonest pathological events. It is, perhaps, in surgical work, especially in bone and joint affections, that tuberculosis is frequently seen as a sequela of injury. Similar lesions of the internal organs resulting from traumatism are of comparatively rare occurrence, and in this connection it may be observed that of all the predisposing and exciting causes of pulmonary phthisis injury to the chest is one about which less has been written than many others of minor importance. It might be supposed that unless the injury to the thoracic wall also involved the lung, as in the case of a bad fractured rib or a perforating wound, it could have but little influence in lowering the vitality of that organ, and so rendering it a more easy prey to tuberculous infection. The case described by Dr. Nogués (*a*) has an important bearing on this point. A criminal was sentenced to one hundred and fifty lashes. At the conclusion of the punishment he was taken away to the prison infirmary in a state of unconsciousness. Within the next few days cough, dyspnœa and hæmoptysis appeared until a condition of phthisis was well advanced. It was stated that the anterior aspects of the lungs were scarcely affected at all. This may appear a somewhat exaggerated instance of the influence of traumatism upon the development of the disease. As a result of a fractured rib from the kick of a horse a man recently recovered substantial damages in the Edmonton County Court, not so much for the injury itself as for the fact that phthisis had ensued, which, according to the medical evidence, was directly set up by the accident. The so-called "accidental phthisis" is, therefore, far from being a myth.

(*a*) *Journ. Amer. Med. Assoc.*, January 23rd, 1904.

Music and Digestion.

THE gratification of one or more of the special senses in some form or other has long been recognised as one of the most agreeable, and at the same time the most valuable, accompaniment of the table. It is not only by stimulation of the palatal nerves that the appetite for food is quickened, the influence arising from the auditory and visual organs upon the digestive processes themselves, when of a pleasing character, are distinctly beneficial. The presence or absence of cheerful surroundings, entertaining conversation, or distant melodious strains materially affect the enjoyment of a meal, such is the power of the mind over the vital functions of the body. The effect of music in this direction was well known to the ancients, and in modern times a restaurant is incomplete without its orchestra. Nor is it the æsthetic and social qualities alone which render melody and harmony such useful adjuncts to the pleasures of the table, for it would seem as if music were capable of directly influencing the gastric functions. Scientific proof of such influence would be difficult, indeed, to provide, especially as these effects are far from constant, and vary in proportion to the individual's susceptibility and musical sense. Thus, the statement recently made in court by a lady to the effect that a certain street-organ produced indigestion is freed from the domain of fancy when considered from the standpoint of the

(*a*) *Lancet*, vol. i., 1888, page 1,044.

musician and the neurologist. The music may have been insufferably bad, a concession which will be readily made, and, at the same time, the reflex nervous arc may have been abnormally excitable. The grinding of the "instrument of torture," in common with other unpleasant external stimuli, may be quite sufficient to exert an unfavourable inhibitory influence upon the digestive processes, even in those who are not of a musical disposition.

The U.S.A. Antitoxin "Trust."

For some time past sensational paragraphs have gone the round of the British Press with regard to the inhumanity of a "corner" in antitoxin, whereby the cost of that absolutely essential drug had been unduly forced up by a few monopolists who controlled the supply. We are glad to learn on no less an authority than that of Messrs. Parke, Davis and Co., one of the three producers of antitoxin in the United States, that the report is based on a misconception of the facts of the case. The exclusion of a weak and ineffective antitoxin, and the sale of a standard product in larger packages, has necessitated a somewhat higher price for the latter. So far from losing, however, the purchaser gains in value received. "For instance," says the *American Druggist*, "the 1,000 unit package now costs $2, as against $2.25, and the 2,000 unit package now costs $3.50, as against the former price of $4." The manufacturers explain their change to larger standard packages on the ground that the tendency is to use larger doses of the remedy, it being safer to use large doses rather than to run the risk of a small dose being insufficient to bring about immunity. That the whole affair is a mere "storm in a teacup" is shown by the fact that at the present moment the original small packages of 500 and 1,000 units can still be purchased at the old prices. We are glad to learn on such good authority that an adequate explanation for the "rise" in the price of American antitoxin may be found in the fallacy above exposed. Finally, it may be noted that no change in prices has taken place in the English market.

The Galway X-Ray Case.

In another column will be found a full and special report of this important case, which has occupied the Dublin Law Courts for many days. We may at once remark that we are in complete accord with the finding of the jury. There was no doubt that the sore was caused by the rays, but both Dr. Colohan and Mr. Haire did their best for the patient. In all new applications of science accidents are bound to occur, and if a medical man is to be exposed to an action for malpraxis and damages on every occasion that such an accident occurs it will put a stop to all advance, and eventually result in depriving patients of much that science has to offer. Dr. Colohan's actions were inspired by the best motives, they were performed with due care, and with the full amount of knowledge that can be expected from a non-specialist in a special subject, and it would have been a miscarriage of justice if he had to suffer on their account. We are glad to see that the College authorities did not retire from the case, although they had the opportunity of so doing, and we trust that they will, in financial matters, come to the aid of their Professor and of their assistant Haire.

A Viceregal Slight to the Medical Profession.

The Lord-Lieutenant of Ireland—the Earl of Dudley—has intimated to the Royal Colleges of Physicians and Surgeons of Ireland that he has withdrawn from their future Presidents the right of private *entrée* to the Levées and Drawing-rooms at Dublin Castle. We presume that Lord Dudley has well considered the necessity for an action which has been regarded by the medical profession as an undeserved slight, and that the withdrawal of a long-existing right was dictated by necessity. The Presidents of the Royal Colleges are the *ex-officio* heads of the medical profession in Ireland, and we cannot agree that their right to the privilege of private *entrée* is a whit inferior to that of the heads of Government offices—for whom the privilege is to be in future reserved. Lord Dudley to be consistent must also deprive the Provost of Trinity College, the President of the Queen's Colleges, and similar officials of the right, and we fear that such a radical action will not meet with general approval. Lord Dudley's action is all the more strange when his personal indebtedness to the Irish medical profession is remembered—an indebtedness which he himself acknowledged, and which he expressed himself as desirous of discharging.

Radium in Malignant Disease of the Throat.

Of all the radio-active substances hitherto introduced into the field of therapeutics none is pregnant with greater hopefulness than radium. That substance has been applied, both in the Old World and in the New, with considerable success to malignant growths in accessible places, such as the cheeks, tongue, and surfaces of the body. Elsewhere in the present number of The Medical Press and Circular we print a remarkable article by Dr. Walsh describing the application of radium to such sensitive structures as the soft palate, tonsil, fauces, and posterior pharynx. The object of the writer is simply to call the attention of the medical profession to the fact that it is henceforth possible to treat cancerous processes of the upper throat and fauces by the direct contact-application of radium. From their peculiar anatomical relations it is obviously difficult, and in many cases impossible to bring the X-ray tube to bear upon those parts. Operation, again, if carried out in that region, has to be so extensive, and is so uncertain in its results, that it is very rarely resorted to. It would be hard to overestimate the importance of a new procedure that brings a reasonable method of alleviation, and possibly of cure within the reach of sufferers from a terrible and hitherto hopeless malady.

PERSONAL.

DR. HENRY CORBY, of Cork, has been elected High Sheriff of that city for the ensuing year.

A SIXTY milligramme tube of radium has been presented to Queen's College by the Lord Mayor of Belfast, Sir Otto Jaffé.

DR. S. H. R. MONTGOMERY has been appointed Inspector-General of the Insane, Western Australia, under the New Lunacy Act.

THE Milroy Lectures for 1904 will be given shortly by Dr. W. Williams on the important subject "Deaths in Children, a Preventible Mortality."

THE Gillson Scholarship in Pathology of the London Society of Apothecaries has been awarded to Mr. Leonard Stanley Dudgeon, M.R.C.P.Lond.

THE Senatus of Edinburgh University has resolved to confer the honorary degree of LL.D. in April next upon Professor Alexander Macalister, F.R.S.,Cambridge.

A PAPER on "Tropical Diseases" will be read on March 8th by Sir Patrick Manson at the West India Committee Rooms, under the presidency of the Duke of Marlborough.

AT a meeting held on February 9th, of the Governors of Steevens' Hospital, Dublin, Dr. Winter was elected Assistant-Physician; Dr. Stephenson, Assistant Surgeon; and Dr. Charles Benson, Anæsthetist.

IT has been decided to invite the Duke of Devonshire, who is the President of Owens College, Manchester, to become President of the Victoria University, in which it is proposed to merge Owens College.

WE regret to hear that Sir Samuel Wilks is lying at his residence at Hampstead suffering from appendicitis. An operation was successfully performed on Thursday last, and favourable progress is reported.

The patients of Dr. John Smith, formerly Vice-President of the Border Counties Branch of the British Medical Association, have presented him with a life-sized portrait on his retirement from practice.

THE important post of Superintendent of Statistics under the Registrar-General of Scotland, left vacant by the death of the late Dr. Blair Cunyngham, has been filled by the appointment of Dr. James Crauford Dunlop.

THE Senatus of the University of Edinburgh has awarded the Cameron Prize in Practical Therapeutics to Professor Niel Finsen, M.D., of Copenhagen, in recognition of his work with regard to light therapeutics.

MR. FREDERICK PURSER, F.T.C.D., has presented the sum of £2,000 to the equipment fund of Queen's College, Belfast, to found a studentship in mathematics in memory of his brother, the late Professor John Purser, D.Sc., who was for many years a member of the staff of the college.

SIR DOUGLAS POWELL will deliver the lecture to the Congress of the Sanitary Institute to be held in Glasgow in July next, and Sir Charles Cameron has accepted the presidency of the Conference of Medical Officers of Health, to be held in connection with the congress.

MR. W. P. JOHNSTONE, M.B.Edin., Witwatersrand, South Africa, has been presented with several valuable mementos by the officers of the 1st Battalion Gordon Highlanders in recognition of his services when in charge of the temporary hospital at Mariasburgh during the recent war.

THE Goulstonian Lectures of the Royal College of Physicians for the year will be delivered by Dr. R. Hutchison, on March 8th, 10th, and 15th, on "Some Disorders of the Blood and Blood-forming Organs in Early Life." The Lumleian Lecture of the same college will be given by Dr. F. Taylor later in March on "Some Disorders of the Spleen."

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

BELFAST.

THE HEALTH OF THE CITY.—At the last monthly meeting of the Corporation, the quarterly report of the city analyst was presented by the Public Health Committee. This report contained some serious statements about the milk supply of Belfast. "From a careful study of the results of my analyses I cannot arrive at any other conclusion than that the milk being supplied to Belfast has diminished in quality during the past two years. It would be difficult to say how far this may be due to the milk regulations, or to the smallness of the fines frequently imposed, even in some serious cases of adulteration. . . . Watering to such a large extent or so frequently as formerly does not now take place, but I am afraid that the use of skimmed or partially skimmed milk as an adulterant is on the increase." Councillor M'Innes, in a vigorous speech, called attention to the gravity of these remarks, considered in conjunction with the high death-rate of infants and young children. The report of the Medical Superintendent Officer of Health stated that in the five weeks ending January 23rd, 233 cases of zymotic diseases had been notified, viz., 86 cases of scarlatina, 58 erysipelas, 27 typhoid, 23 simple continued, 17 diphtheria, 14 small-pox, 6 puerperal fever, and 2 membranous croup. During the same period the total deaths numbered 869, and the births 1,034. The deaths from zymotic diseases numbered 88, those from phthisis and diseases of the respiratory organs 107 and 310 respectively. The annual death-rate from all causes was 25·3, or 1·2 more than the corresponding period last year.

BELFAST UNION AND BOARDING-OUT OF CHILDREN.—At the present time the Belfast Guardians have placed no less than 155 children out at nurse, and at a recent meeting of the Board a most interesting report on them was received from Mrs. Dickie, the Local Government Board Inspector, which is worthy of note by all medical men concerned with Poor-law work. She states that the boarding-out system possesses one great advantage over all other systems, and that nowhere has this been more impressed on her than in Belfast, and that is, that the children acquire a *home*, where they make friends, are nursed in sickness, and often live on in after they go to work. "Of the boys who go into the Army and Navy, the majority write 'home' frequently, sending money from time to time, and they come 'home' on furlough as if they were members of the family. Other systems may turn out children better disciplined and better trained, and, where the supervision is inadequate, even better treated and better fed; but no other system provides those somewhat indefinable adjuncts which go to make a 'home.' This, in the boarding-out system is, I think, too often overlooked, and yet it is one of the most humanising influences which can be brought to bear on the waifs and strays of our population with which the Poor-law has to deal."

THE CENTRAL MIDWIVES BOARD AND IRISH MATERNITY HOSPITALS.

Sir,—Will you kindly insert the following correspondence, which has taken place in reference to the examination of midwifery nurses to be held under the direction of the Central Midwives Board ?—

I am, Sir, yours truly,
E. Hastings Tweedy, F.R.C.P.I.
Rotunda Hospital, Dublin, February 8th.

Rotunda Hospital, Dublin,
January 25th, 1904.

Dear Sir,—I shall feel much obliged by your bringing the following matter before your Board, as it is obviously of much importance that a definite pronouncement should be obtained as to the position our midwifery nurses, trained in the Rotunda Hospital, will occupy in respect to the State Examination to be held under the direction of the Central Midwives Board.

The training of our midwives is strict and full, including everything that is requisite for making a good nurse. They reside for a period of six months in the hospital; they watch the progress of over 200 confinements, of these they personally conduct at least two; they have to make not less than ten vaginal examinations; they palpate many scores of abdomens; they attend the lying-in woman from the time of her admission to the hospital to her discharge on the eighth day; each nurse takes entire charge of three lying-in women daily, with their respective children during the puerperium; they take records of temperatures and pulses, under the supervision of the Master of the hospital and the assistant masters; they receive constant instruction in the art of midwifery, are systematically trained in asepsis and antiseptics; they pass catheters, give enemas, are taught to distinguish between normal and abnormal labours, and finally do not receive our certificate until a stringent examination has been passed.

The Rules that at present seem to preclude them from qualifying are as follows:—

Form III.—A woman must have "attended and watched the progress of not fewer than twenty labours, making abdominal and vaginal examinations during the course of labour, and personally delivering the patient."

Form IV.—A woman has "to my satisfaction nursed twenty lying-in women during the ten days following labour."

It would be impossible for our resident nurses to follow the course of the puerperium for ten days, as Irishwomen will not remain in hospital for more than eight days. In this connection it may be mentioned that the Scottish Universities and Conjoint Boards require a student to produce evidence that he has personally conducted twelve cases of labour, or that he has taken out a three months' course in a recognised institution, in which case the personal conduction of six cases is sufficient. Durham University requires a student to have personally conducted twenty cases of labour, or to have attended the indoor practice of a lying-in hospital for three months. Dublin University, London University, and the Royal University of Ireland compel a student to take a six months' course in a lying-in hospital, but they do not specify any necessary number of personal conductions, and they refuse altogether to recognise instruction received, or labours attended elsewhere than in a lying-in hospital.

I may summarise by saying that the licensing bodies and Universities regard a six months' course of instruction in a recognised lying-in hospital as the ideal training in practical midwifery for a student; that some of them accept a three months' course, with the addition of a small specified number of personal conductions; and that only those who do not require any proof of attendance at a recognised institution require even a medical student to personally conduct as many as twenty labours.

It will thus be seen that a course of six months' instruction in the intern department of a lying-in hospital is regarded as the ideal training for the medical student, and as being much preferable to a longer course of instruction from a non-hospital practitioner, and that the reasons which render this course much better in the case of the medical student are still more cogent in the case of the midwife, who admittedly is best trained when trained in a hospital.

Taking all these facts into consideration, and having regard to the undoubted spirit of the Bill which was framed in the interests of the lying-in patient, I trust that your Board will be able to accept our curriculum as an equivalent, or to make such exception or modification in the present rule as will enable our nurses to qualify for the State Examination in Midwifery.

I remain, yours faithfully,
E. Hastings Tweedy,
Master, Rotunda Hospital.
To the Secretary, Central Midwives Board.

Central Midwives Board,
6 Suffolk Street, Pall Mall,
London, S.W., Feb. 1st, 1904.

Dear Sir,—Referring to your letter of January 25th, I have to inform you that the subject raised therein was taken into consideration by the Board at their meeting on the 28th ult. I am directed to point out that the Rules were approved by the Privy Council on August 12th, 1903, for a period of three years, and to forward you a copy of the resolution, which, having regard to that fact, the Board passed unanimously.

I remain, yours faithfully,
G. W. Duncan, Secretary.
The Master of the Rotunda Hospital, Dublin.

Copy of a resolution moved and carried at the meeting of the Central Midwives Board, held on January 28th, 1904:—

"That, having considered the letter addressed to them by the Master of the Rotunda Hospital, the Board regret that the suggested alterations were not brought to their notice before the Rules were sent to the Privy Council, as having been now approved by that body it is impossible for the Board to alter them."

[The above correspondence is of first importance not only from the point of view of the Irish maternity hospitals, but also of the whole administration of the Midwives Act. That measure was conceived and passed in the interest of the child-bearing population of the United Kingdom. If its administration is to be inaugurated by the exclusion of the midwives who admittedly have a training second to none in the Kingdom, things had better have been left alone. What have Mr. Heywood Johnstone and other active supporters of the Act to say as regards this retrograde and short-sighted policy? The subject is dealt with in a leading article of our present issue. It cannot be allowed to rest in its present unsatisfactory position, which is simply an outrage upon common sense and justice, and the spirit of what is, upon the whole, a salutary Act, at any rate in its inception.—Ed.]

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

LIFE ASSURANCE FEES FOR MEDICAL EXAMINATIONS.

To the Editor of The Medical Press and Circular.

Sir,—In your issue of January 27th you call attention to the fact that certain insurance companies are now "sweating" the medicals in the matter of fees. This, too, when the united funds and the annual income of the life assurance business are going up by leaps and bounds. Well, I am glad to see this coming about. If any class of men think they will get their proper dues in this life without organisation and combination, then such "men"—if we can call them men—must stand their being taken at only their own value. The "nigger" is not thought much of, and evidently medicals are at a discount. Why? All over England 80 per cent. of the medicals are quite willing—to judge by their actions—to give medical and surgical treatment and medicine for one penny a week.

Please do not think I am making a joke! Also, over 5,000 are now gladly taking a half-penny per week from life assurance offices, who supply medical aid and death policy. I think this is quite too excessive payment for such doctor "men."

But there is a much graver side to this question—the question of honesty. Honesty in examinations and honesty in reports. Now in common it is quite understood that if an employé is paid a smaller salary than he deserves, he is supposed to make up the difference by swindling his employer. In this country swindling is not a crime—unless one is found out. Now that insurance against sickness is widening out there is a wider field for agreement between the patient and the doctor as to stating that the disease is an "insured disease," while it is not. In such a case the medical will "get even" with the company. Again, in cases where a medical sees that a patient has died from a disease for which the company will refuse to pay, here again the medical can "get even" with the company by substituting another named disease. Again, take the case where a medical is asked to "put a patient in order," so that he can run the best chance of "doing" the company's medical! Again, take the case where the patient asks the medical to put him up to what he should take to make him look and feel seedy, with a view to getting good terms for an annuity, and soon.

Now, I have no sympathy with any company which cuts down the examination fee—because the company "can get a medical who will do it for less." Such deserve scant respect. While the companies, and the public, too, become wealthier, they think it *right* to cut down medical fees. Amongst the working-men they laugh at the "club doctor's physic." The time will come when doctors who examine for companies will be similarly laughed at, and where mutual contempt and distrust will set in.

The public have this matter in its own control. Let the public try to act with honesty, and the profession will not fail to serve them faithfully.

I am, Sir, yours truly,
ROBERT R. RENTOUL.

[We have inserted the foregoing letter, but think it well to record our conviction that in our own country the honesty of the medical insurance examination is not a matter of fees. At the same time we agree that to lessen fees is not the way to strengthen the standards of honesty. Highly skilled and responsible services demand an adequate reward. A general lowering of medical fees on the part of the insurance companies would probably end, sooner or later, in disaster.—ED.]

ALOPECIA AND DENTAL CARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of your correspondent "M.R.C.S., L.D.S.," comes upon one like a hot blast of a simoon. It passes away, however, and one is not "a penny the worse." In my letter of the 3rd inst., I remarked: "The statement that the solid constituents of the teeth, once deposited, undergo no further change" seemed to me pure assumption. "M.R.C.S." accepts this as an assertion from me that they undergo such a change. Heaven forbid! He then proceeds to pulverise and annihilate me for what I never said. Let me hasten to say that I have the greatest respect for the brilliant researches of the late Sir John Turner. I have not found time to refer to his work, but I dare swear he never made any dogmatic statement that the solid constituents of teeth, once deposited, *never* change. Why does not "M.R.C.S." support his case by a concise quotation from Turner? His generalisations seem to hinge chiefly upon the reverence one should have for Turner. It is this blind, unquestioning acceptance of authority that constantly proves the greatest hindrance to scientific progress.

"M.R.C.S." is evidently a master of his subject, but why be angry? It so happens I have a nodding acquaintance with the work of Miller in the microbic invasion of the teeth. I do not see that my argument as to some teeth being obviously less resistent than others is upset by anything in your correspondent's didactic criticisms. Some teeth break off short in youth and middle age, while others last for a hundred years—some decay early, others do not decay at all, and last for a long lifetime whole and sound. Why should "M.R.C.S." wax indignant because I assume there is some difference of structure in teeth as in other tissues, that makes them more or less resistent to microbial and other adverse invasions, and accounts for the differences in question?—

I am, Sir, yours truly,
MEDICUS SENEX.

Literature.

HERBERT ON CATARACT EXTRACTION.(a)

THIS small practical handbook has passed already into its second edition, and Major Herbert has taken the opportunity to set right a number of small errors and has brought his statistics up to March, 1903.

We have already during the past year reviewed this book at length, and we have nothing further to add, save to insist that it is an eminently suitable work for all ophthalmic surgeons to possess, and we have great pleasure in recommending it. The change from a stiff cloth to a limp leather cover has greatly increased the handiness of the book, and we have little doubt this second edition will confirm the opinions formed by leading ophthalmic surgeons of the book when it first appeared a short while since.

THE AFTER-TREATMENT OF OPERATIONS.(b)

THIS is a difficult subject to put in a handy and useful form, for the after-treatment of operation cases adopted by different surgeons varies very considerably. But, as the author states in his preface, "no good purpose would be served by a recital of all the different methods"; he has, therefore, given in each case that line of treatment which seems to be most practical. We must congratulate Mr. Mummery on the excellent way he has performed his task, for the book is wonder fully complete. The chapters we would like particularly to praise are those dealing with abdominal operations—*viz.*, Chapters XII. and XIII., and Chapter IV. on "Shock and Collapse"; the latter, based as it is on the more recent physiology of the subject, tends to put the treatment of this complication on a more scientific footing.

This book, which replaces a long-felt want, is one we can strongly recommend, not only to the practitioners and house surgeons for whom it is intended, but to everyone concerned in the successful after-treatment of operations.

ELEMENTS OF SURGICAL DIAGNOSIS. (c)

WE welcome the third edition of this useful little book. The whole text have been revised, much has been rewritten, and many additions have been made.

A section on the diagnosis of the intra-cranial complications of middle ear disease has been added to the chapter on diseases of the head. This is an important addition, and the author deals with it in a very clear manner.

Two new chapters have been introduced, one on the diagnosis of abdominal tumours, the other on certain acute abdominal diseases for which surgical aid is now

(a) "The Practical Details of Cataract Extraction." By H. Herbert, F.R.C.S.Eng., Major I.M.S., Professor of Ophthalmic Medicine and Surgery, Grant Medical College; in charge of the Sir Cowasjee Jehangir Ophthalmic Hospital, Bombay; Fellow and Late Syndic of the Bombay University. Second edition. London: Bailliere, Tindall and Cox. 1903. Pp. x and 114. Illustrations and plates. Crown 8vo, price 4s. net.

(b) "The After-Treatment of Operations." By P. Lockhart Mummery, F.R.C.S.Eng., B.A., M.B. B C.Cantab., Demonstrator of Operative Surgery, St. George's Hospital; late senior House Surgeon, St. George's Hospital. London: Bailliere, Tindall and Cox. 1903. Pp. viii. and 221. Illustrations 29. Crown 8vo, price 5s. net.

(c) "Elements of Surgical Diagnosis." By A. Pearce Gould, M.S.Lond., F.R.C.S Eng. Third Edition, revised and enlarged. London, Paris, New York, and Melbourne: Cassell and Co., Ltd. 1903.

sought. These two chapters go far towards making the book thoroughly up to date, and we consider them of great value. We can strongly recommend this book to all students, and it will well repay most practitioners to read it.

YEAR-BOOK OF PHARMACY. (a)

This excellent year-book contains a good account of the investigations on the subject of radium, together with a summary of the history of the element, by C. W. Ranolt. Everything connected with this marvellous substance which has already given pause to many of our fundamental theories on chemistry, is deeply interesting, and the concise statement of Mr. Ranolt makes the present volume one of the most valuable of a very valuable series. Hardly less interesting are the experiments of H. Moissau on the behaviour of the allotropic forms of carbon at high temperatures. Old-established views are further shaken by J. Dewar's demonstration that fluorine retains its chemical activity at very low temperatures—252° C. Coming to materia medica we find that ipecacuanha still gives occupation to analytical chemists without much reward for their labour. Mr. Mueller's suggestive and useful paper on the solubilities of alkaloids is given with sufficient fulness to allow of his experiments being followed and understood. The continuous struggle between sophistication and analysis is well-known in the study of essential oils, notably in the adulteration of peppermint oil with triacetin, which apparently largely increases the ester value of the oil. It is interesting to note that there is a growing tendency to use curious animal products, and as we read Kebler's and Pancoast's papers on bear's grease, rattlesnake oil, and skunk oil, we seem as if reading a page of Bullen's "Quincy," or "Culpeper," or Mr. Brooks' "Batu na Abubuan Hausa," in which he describes the making of the Hausa arrow poison, thus :—"Seek the head of the striped snake, the head of the black snake, and the fruit of wild lime, pepper, and tobacco. These are all mixed together, pounded, and put into a clay bowl, boiled and smeared on a spear." We are glad to notice that the editors consider that many of the new remedies foisted on the notice of therapeutists as synthetic preparations are unworthy of notice. Some formulæ from the new Pharmacopœia of St. Thomas's Hospital, and from formulæ employed in British naval hospitals, are included ; which cannot but be helpful to the practitioner. We have given more space than usual to this year-book, for we think that our medical brethren cannot know how much information it contains or they would more generally subscribe for it.

WARDEN'S HANDBOOK TO THE PARIS MEDICAL SCHOOL. (b)

This is an extremely useful little guide to the Paris hospitals. Under each is given a list of physicians and surgeons with their hours of attendance. The readiest means of reaching the various hospitals mentioned is clearly set out, so that foreigners may have no difficulty in finding their way about. A table of the medical societies is supplied with their dates of meeting and correct addresses. The best part of the guide is that entitled "Daily Diary," in which we have noted down under each day of the week the names of the various lecturers, their hours, subjects, and place of meeting. The foreigner may be surprised to find Sunday included, but in Paris this is no day of rest for those holding hospital appointments in the same sense as it is here. A list is also given of the Paris members of the Continental Anglo-American Medical Society. We have no doubt Dr. Warden's pocket-book will find a home in many a medical vagabond's pocket. We trust he will keep the work well up to date, and would suggest that a smart map of Paris indicating the situation of the various hospitals and medical and scientific institutions should be added in the next edition.

(a) "Year-Book of Pharmacy, comprising Abstracts of Papers Relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and foreign journals from July 1st, 1902, to June, 1903." By J. O. Braithwaite. London: J. and A. Churchill. 1903.

(b) "An English Handbook to the Paris Medical School." By A. A. Warden, M.D., Visiting Physician to the Hertford British Hospital, Paris. Price 2s. net. London: J and A. Churchill. 1903.

Obituary.

DR. GEORGE PATRICK O'CONNOR.

The accidental death of Dr. George Patrick O'Connor at the early age of thirty-one will be the cause of much regret to his many friends in Ireland. At the beginning of the year he met with a carriage accident, being thrown over a precipice one hundred feet in depth, and sustained injuries which proved fatal a few weeks later. Deceased was the son of Dr. M. O'Connor, of Chatteris, Cambridgeshire, and was Medical Officer of Health for Harding in Alfred County, South Africa. His death took place at Pinetown Bridge, Natal.

DAVID THOMSON PLAYFAIR, M.D.

By the death of David Thomson Playfair, M.D., Bromley has lost one of its busiest and most popular medical practitioners. His death took place somewhat suddenly at Bournemouth at the comparatively early age of forty-eight. He was a son of the Rev. David Playfair, of Abercorn, N.B. He studied at Edinburgh, where he qualified as L.R.C.S. and P. in 1877, M.B., C.M. or Edinburgh University in the same year, and M.D. in 1888. For many years he acted as honorary medical officer to the Bromley Cottage Hospital. Deceased was well-known as a skilful musician and photographer. Death was due to appendicitis.

MR. WARBURTON, M.R.C.S., L.S.A.

We regret to announce the death of Mr. Warburton, of Treherbert, a well-known medical practitioner. Deceased, who was sixty years of age, had carried on practice in the neighbourhood for the last thirty years, during the whole of which period he acted as surgeon to the Ynsfew and Blaenavon Colleries.

DAVID PORTEOUS, M.D.GLASG.

We regret to announce the death of Mr. David Porteous, who was medical officer to Sir John Ross's expedition in 1850 to the Arctic regions in search of Sir John Franklin, at Middleton St. George, Darlington, recently, at an advanced age. In early manhood he was an assistant-surgeon in the Navy, and had medals for service in the Arctic region, in the Baltic and Crimean campaigns, and in the Indan Mutiny. He graduated as M.D. of Glasgow in 1848 and for thirty years practised at Middleton.

DUNCAN CAMPBELL LONGDEN, M.B., M.R.C.S.ENG., D.P.H.ED., F.R.C.S.ED.

It is with much regret we announce the death of Mr. D. C. Longden, at his brother's house in London, at the early age of 37. His education began in 1884 at Edinburgh University, where two years later he took a gold medal in anatomy, and later became Senior Demonstrator of Anatomy. Some time after qualification he became lecturer on anatomy at the School of Medicine for Women, but some years later was compelled to go abroad on the return of chest symptoms. For five or six years he acted as surgeon to a steamship line, and then became Medical Officer to the Boer Refugee Camp. Soon after his return home his fatal illness was ushered in by an attack of hæmoptysis, and the end speedily came to a career of more than usually brilliant promise.

E. C. GARLAND, M.R.C.S., D.P.H., OF YEOVIL.

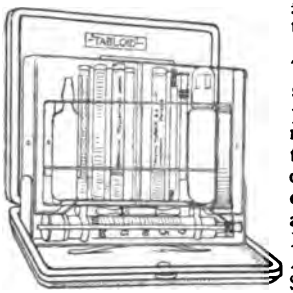
The death took place recently at Yeovil, of Dr. Garland, Medical Officer of Health of that town. Deceased, who was 70 years of age, was educated at Sherborne School, and qualified as M.R.C.S. in 1855. He also held the diplomas of L.S.A., L.R.C.S., and L.R.C.P.Ed., and D.P.H. He was consulting surgeon to the Yeovil Hospital, and for many years Deputy

Coroner for the late Dr. Wybrants, of Shepton Mallet. His loss will be felt by a wide circle of friends and by his two children.

New Inventions & Medical Appliances.

THE HYPODERMIC "TABLOID" BRAND POCKET CASE (No. 21.).

THE attention of medical men generally may be drawn to the Hypodermic "Tabloid" Brand Pocket Case (No. 21), which is now issued in gun-metal. All in want of an aseptic hypodermic outfit may avail themselves of this useful and extremely compact case. The outside measurements are 3½ ins. by 3¼ ins. by ¾ in., and the case may therefore be carried in the waistcoat pocket. The fittings comprise a special detachable nickel-plated aseptic frame and revolving rack for nine tubes of "Tabloid" hypodermic products, capsule of ether, glass stoppered and capped phial, the B. W. and Co. All-Glass Aseptic Hypodermic Syringe, with one exploring and two regular needles. This *multum in parvo* is one of the neatest and most ingenious cases ever contrived to lighten the anxiety of the busy practitioner. Armed with this, he may with confidence encounter many an emergency when thrown upon his own resources far from the aid of chemists or consultants. For every-day routine work it is simply perfect and unsurpassable in its up-to-dateness.



Medical News.

Lectures on Medical Jurisprudence.

On February 4th, Dr. F. J. Waldo, coroner for the City of London, delivered the fourth of a series of six lectures before the Council of Legal Education at the Old Hall, Lincoln's Inn. Sir Alfred Marten, K.C., vice-chairman of the council, presiding. Dr. Waldo said that the two standpoints, that of law and that of medicine, with regard to insanity were of a different nature, although both agreed in the absence of any satisfactory definition of the term "insanity." He then described at some length the various types of "medical insanity" from the modern point of view—namely, mania, melancholia, delusional insanity, general paralysis dementia, and idiocy. One practical fact insisted upon was the necessity of a medical examination of persons of previously blameless life who suddenly committed some offence that brought them into the custody of the police, as it not infrequently happened that the prisoners were not responsible for their actions. The second halt of the lecture was devoted to the legal attitude with regard to insanity, chiefly in its particular application to the criminal responsibility of the insane. Lord Hale in 1675 ruled that "if a traitor become *non compos mentis* before conviction he shall not be arraigned; if after conviction he shall not be executed." In 1843 the House of Lords repudiated the old test of sanity as an abstract knowledge of right and wrong and substituted a knowledge of right and wrong as regards the particular crime of which a person was accused.

Royal College of Surgeons in Ireland.

THE annual charter dinner of the Royal College of Surgeons in Ireland took place in the College, Stephen's Green, on Saturday night. The Museum, in which the dinner was served, was tastefully decorated. At either end of the room were large representations of the Royal Arms and motto, and numerous flags were neatly arranged in various positions.

Sir Lambert H. Ormsby, President of the College, occupied the chair, having on his right his Excellency the Lord Lieutenant, the Right Hon. the Earl of Westmeath, Right Hon. Mr. Justice Ross, Sir Philip Smyly, Sir Christopher Nixon, Sir Charles Cameron, C.B., Sir Charles Ball, and Sir Augustine Baker. To the left of the President were Lord Ashbourne, Lord Chancellor of Ireland; Lord Plunket, K.C.V.O.; the Right Hon. Sir Anthony P. MacDonnell, K.C.S.I., K.C.V.O.; the Hon. A. Browne, Sir Arthur Macan, President Royal College of Physicians; Sir James Murphy, Bart., and Major-General Vetch, Commanding 13th Infantry Brigade, Dublin. The vice-chairs were occupied by Mr. G. F. Blake, J.P., Registrar, and Mr. J. Barton, F.R.C.S., Secretary to the Council.

After dinner, and the toast of "The King" had been proposed, the President proposed the toast of "His Excellency the Lord Lieutenant, and prosperity to Ireland." His Excellency, in returning thanks, said that it had been suggested that in some of his speeches he had used vague and ambiguous language. He had always attempted to be frank and straightforward in the opinions he had expressed. While not claiming that the utterances of the Lord Lieutenant should be absolved from legitimate criticism, he protested against their being invested with meanings that were never intended. He specially objected when this was done by people sitting in London whose opinions were cramped by the recollection of past discomfitures. As to the Land Act, there were undoubtedly some defects in its provisions which it would be their duty to rectify on the earliest possible occasion. However, having regard to the present state of the money market, it was by no means an unmixed evil that the Land Act should be working steadily but surely. He echoed the opinion expressed by the President of the College that land purchase would not have the effect of driving the resident gentry from Ireland.

Sir Thomas Myles proposed, "The Navy, the Army, and Auxiliary Forces." Sir Charles Cameron proposed "The Royal College of Physicians," the Vice-president of the College, Mr. Chance, "The Guests," and the Lord Chancellor, "The Royal College of Surgeons."

The Royal University of Ireland.

LIST OF EXAMINERS IN MEDICAL SUBJECTS FOR 1904.

IN THE FACULTY OF MEDICINE.

Anatomy.—Ambrose Birmingham, M.D., Joseph P. Pye, D.Sc., M.D., Johnson Symington, M.D.

Physiology.—John J. Charles, M.A., M.D., Denis J. Coffey, M.A., M.B., B.Ch., B.A.O., *T. H. Milroy, M.D.

Medicine.—*James A. Lindsay, M.A., M.D., John I. Lynham, M.D., M.Ch., M.A.O., *Joseph F. O'Carroll, M.D.

Surgery.—John S. M'Ardle, F.R.C.S.I., Charles Y. Pearson, M.D., M.Ch.

Ophthalmic Surgery.—*Arthur W. Sandford, M.D., M.Ch., *Louis Werner, M.B.

Midwifery.—*John W. Byers, M.A., M.D., M.A.O., *Alfred J. Smith, M.B., M.Ch., M.A.O.

Medical Jurisprudence and Sanitary Science.—*Patrick T. O'Sullivan, M.D., Antony Roche, M.R.C.P.I.

Materia Medica.—*Martin Dempsey, M.D., *Sir William Whitla, M.A., M.D.

Pathology.—*Edmond J. M'Weeney, M.A., M.D., *James Lorrain Smith, M.D.

Sanitary Science.—*Sir Charles A. Cameron, C.B., M.D.

EXTERN EXAMINERS.

Surgery.—*Charles Stonham, F.R.C.S.E.

Midwifery.—*Henry Jellett, M.D.

Pathology.—*Alexander C. O'Sullivan, M.D.

Ophthalmology.—*William G. Sym, M.D.

Examiners marked thus (*) were reappointed for the year 1904. The names of Fellows of the University are not marked. Mr. Jack and Mr. McElderry are appointed for 1904.

Volunteer Army Medical Corps.

COUNTESS HOWE recently distributed the prizes to the London Volunteer Companies of the Royal Army Medical Corps. Colonel J. E. Squire, explaining the position, said he was obliged to report a further diminution of the strength of the corps. At the end of 1901 the total was 471; a year later 440, and last year 383. The letters of resignation were nearly all to the effect that the writers were unable to comply with the new Volunteer regulations. With regard to recruits, they were only 57 last year, against 113 in 1901. Only with regard to numbers had the corps cause for regret. Its efficiency was as high as ever, and in some respects higher. The prizes having been distributed, Colonel Squire asked Lady Howe to unveil an oak tablet on one of the walls of the hall recording the names of 86 members of the corps who served in the South African War. Lady Howe, having unveiled the memorial, said she could testify to the excellence of the men of this corps from the reports she received of them and their comrades when they manned the Imperial Yeomany Hospital and Bearer Company in South Africa.

Balneological Congress at Aachen (Aix-la-Chapelle).

THE twenty-fifth Balneological Congress will be held at Aachen from March 3rd to 7th, under the presidency of Herr Liebreich, of Berlin. The opening ceremony is announced to take place at the Kurhaus at 8 p.m. on Thursday, March 3rd. The Congress will open at ten on the following morning with speeches from Herr von Hartmann, "Regierungs Präsident"; Herr Veltmann, "Oberbürgermeister"; Dr. Breuler, rector of the Hochschule; Dr. Beissei, Sanitätsrath; and others. Communications are announced from Herr Polis, of Aachen, on "The Climatic Conditions of the Rhine Provinces"; Herr Burwinkel, of Nauheim, on "Acute Rheumatism in the Joints"; Herr Rothschild, of Soden, on "The Climatic Treatment of Heart Complaints"; Herr Kugler, of Marienbad, on "Balneophysics and Climatic Health Resorts"; and others. Among the entertainments there will be a special performance of Haydn's "Creation" in the large concert-room of the Kurhaus. Further particulars will be supplied by Herr Sanitätsrath Dr. Beissel, 18 Kleinkolnstrasse, Aachen.

The Royal Commission on Shell-fish.

A CONFERENCE of oyster merchants and others interested in the shell-fish industry was held at the Great Eastern Hotel, Liverpool Street, London, on Friday, February 5th. Mr. D. J. Morgan, M.P., presided, and the business was to consider the recent report of the Royal Commission on Sewage Disposal bearing upon the protection of shell-fish layings.

Darmstadt Poisoning.

THE eleventh death from the eating of poisonous beans at Darmstadt has occurred. The latest victim was an elderly lady, who was one of the first to exhibit the symptoms of poisoning, but she had so far recovered that the doctor on Tuesday considered her out of danger.

PASS LISTS.

Army Medical Service.

THE following is the official list of Candidates who were successful at the recent examination in London for Commissions in the Royal Army Medical Corps, and for which fifty-eight candidates entered :—

Marks.	Names.
590	Rugg, G. F., M.R.C.S.Eng., L.R.C.P.Lond.
588	Thomson, D. S. B., B.A., M.B., B.Ch., B.A.O. Dub.
562	Arthur, A. S., M.B., B.S.Durh.
555	Fairbairn, J., M.B., B.Ch.Edin.
542	Anderson, R. G., M.R.C.S.Eng., L.R.C.P.Lond.
542	Bousfield, L., B.A., M.B., B.C.Cantab., M.R.C.S. Eng., L.R.C.P.Lond.
540	Douglass, J. H., B.A., M.D., B.Ch., B.A.O., D.P.H.Dub.
537	Le Bas, D., M.R.C.S.Eng., L.R.C.P.Lond.
532	Lewis, R. R., M.R.C.S.Eng., L.R.P.Lond.
527	Turner, C. H., M.R.C.S.Eng., L.R.C.P.Lond.
526	Noke, F. H., M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond.
520	Cathcart, G. E., M.R.C.S.Eng., L.R.C.P.Lond.
519	Whitehead, E. C., M.B.Lond., M.R.C.S.Eng., L.R.C.P.Lond.
518	Lucas, T. C., B.C.Cantab., M.R.C.S.Eng., L.R.C.P. Lond.
511	Turnbull, J. A., L.R.C.P. and S.Edin., L.F.P.S. Glasg.
509	Wiley, W., B.A., M.B., B.Ch., B.A.O.Dub.
508	Hole, R. B., M.B., B.Ch.Edin.
506	Otway, A. L., B.A., M.B., B.Ch.Dub.
503	Vaughan, W. F. H., M.R.C.S.Eng., L.R.C.P.Lond.
500	Grant, M. F., B.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond.
500	Harding, H., M.B., B.Ch.Edin.
495	Johnstone, D. P., L.R.C.P. and S.Edin, L.F.P.S. Glasg.
489	Moore, E. H. M., M.R.C.S.Eng., L.R.C.P.Lond.
480	Garland, F. J., M.B., B.Ch., B.A.O., R.U.I.
478	Ahern, M. D., L.R.C.P. and S.Edin.
472	Connell, H. B., L.R.C.P. and S.Edin.
468	Hayes, G. S. C., M.R.C.S.Eng., L.R.C.P.Lond.
462	Bowle, S. C., M.R.C.S.Eng., L.R.C.P.Lond., L.D.S.Eng.
461	Meaden, A. A., M.R.C.S.Eng., L.R.C.P.Lond.
457	Cahill, R. J., M.B., B.Ch., B.A.O., R.U.I.

Royal College of Physicians, Edinburgh, Royal College of Surgeons, Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on the 29th ult., with the following results :—

Final Examination.—Of 66 candidates entered the following 38 passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G. :—Edith Serjeant, Hunts; Walter Alphonso Dorion, Canada; James Sydney Cooper, London; Alexander Hugh Blaxell Pearce, Edinburgh; Harry Lorne Pavey, Canada; Robert Brodie Anderson, Canada; Rupert Allen Clayton Rigby, Ceylon; John Daly Nicolas, Calcutta; John James Andrews, Montreal; Ida Margaret Guillaume, London; Leo Ferdinando Bianchi, England; William James Purves, Hartlepool; Henry Murray Agnew, Lurgan; William Rotherham, Lancs.; Joseph Stark, Lanark; William Black Hendry, Edinburgh; James MacGregor, Montreal; Henry Maurice Madden, Cork; Samuel James Mathewson, Tyrone; Ian Campbell, Perthshire; Henry Ronald Leonard, Malta; Patrick Shaw, Melbourne; Jesudawson Joseph Anthony-Pillay, S. India; Sheik Nizam ud din, Punjab; Edward Rolston Langrill, Toronto; Ram Sarup Varma, India; Andrew Malachy Walsh, co. Waterford; John Herbert Yearsley, Welshpool; John Mounette Huey, Londonderry; Denham Cecil Woods, India; Thomas Sargent Pearse, New Zealand; Eulalia Sisley Richards, Battle Creek, Mich.; Charles Henry Arthur Alderton, India; William Lang Hodge, Plymouth; John Watson, co. Armagh; Houland Samuel Rasaiah, Ceylon; Kershaw Dinshah Khambatta, India; and Sidney Percival Joseph, Ceylon; and 11 passed in medicine and therapeutics; 1 in surgery and surgical anatomy; 4 in midwifery; and 3 in medical jurisprudence.

Trinity College, Dublin.

THE following candidates passed the Final Examinations in surgery at the Hilary term, 1904 :—Thomas C. A. Sweetman, Robert Bailey, Charles E. Moore, Winslow S. S. Berry, Washington P. Tate, John C. Hall, Herbert Stone, William M. Wade.

Conjoint Examinations in Ireland.

THE following have passed the examination for the Conjoint Diploma in Public Health :—Joseph P. Dee, M.B., &c., R. Julyan George, M.B., &c., Christopher A. Johns, M.B., &c., J. M. S. Levis, L.R.C.P.&S.I. (Honours), Thos. J. Nicholl, L.R.C.P.&S.I., E. M. J. O'Farrell, F.R.C.S.I., Thos. Rhind, M.R.C.S., L.R.C.P., Alex. W. Sampey, L.R.C.P.&S.I., Lieut. R.A.M.C. (Honours), Ed. J. Tynan, F.R.C.S.I.

THE General Medical Practitioners' Association has circulated some adverse comments on the new London University scheme for centralising the teaching of medical science subjects. It maintains that these subjects can best be taught, as now, in class-rooms of moderate size rather than in vast and crowded laboratories in South Kensington.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

NEW TREATMENT OF RENAL AND CARDIAC DROPSY.

Our French correspondent has sent us the abstract of an important paper by Professor Renaut on a new treatment of renal and cardiac dropsy with reports of cases in which it had proved very efficacious. Report in our next issue.

A PROVINCIAL PRACTITIONER.—If you will furnish us with data on which to form an opinion, we shall be pleased to go into the matter and state our views.

A CORRESPONDENT writes:—"What fee should I charge a patient—living in a £28 per annum rental—for the operation of injecting diphtheritic serum.—(*a*) When on my ordinary round? (*b*) When as a special visit, two miles off and a cab fare of 2s. 6d, at 8.30 p.m.?" [Perhaps some of our readers will furnish the desired information, —ED].

A SHEFFIELD SURGEON.—The craze for erecting large and costly sanatoria for consumption must speedily come to end. The essence of successful treatment of tuberculosis is isolation and simplicity.

U. A. S. (Enfield).—The case would be most suitable for treatment in the house of a medical man. There is an association in Bournemouth for the registration of medical men who can take such resident patients. The Hon. Sec. is Dr. Crallan.

BURGOYNE.—Madeira is generally considered unfitted for gouty persons. That is so, speaking generally, but if the patient be abstemious, as a rule a glass of sound Madeira now and then will do no harm. *Crede Experto.*

DR. PEARSE (Plymouth).—We hope to have space for your paper on 'Immunity" in an early number.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 17th.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Mr. C. L. Curties: Exhibition of Specimens of Marine Objects mounted by Mr. H. J. Waddington. Papers:—Mr. E. M. Nelson: (1) On the Vertical Illuminator; (2) The Influence of the Antipoint on the Microscopic Image shown Graphically.—Mr. K. Lucas: A Microscope with Geometric Slides.

ROYAL METEOROLOGICAL SOCIETY (Institute of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m. Papers:—Mr. E. Mawley: Report on the Phrenological Observations for 1903.—Mr. W. H. Dines; Observations by means of Kites at Crinan in the summer of 1903.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. E. Owen: Clinique. Surgical.) 5.15 p.m. Mr. S. Stephenson: Some of the Newer Remedies in Eye Disease.

THURSDAY, FEBRUARY 18th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique (Surgical.) 5.15 p.m. Mr. E. Clarke: Errors of Refraction, their Diagnosis and Treatment.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy Square, W.).—5 p.m. Dr. T. N. Kelynack: Principles and Practice of the Sanatorium Treatment of Consumption. (Post Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6.15 p.m. Dr. M. Dockrell: Fungus Diseases of Skin. (Chesterfield Lecture.)

FRIDAY, FEBRUARY 19th.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square. W.).—8.30. p.m. Paper:—Dr. M. Coplans: The Etiology of Scurvy.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. D. Grant: Clinique. (Ear.)

MONDAY, FEBRUARY 22nd.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover Square, W.),—Papers by Mr. Cornelius Robbins and Mr. J. Thornton Carter on Further Notes on some Prehistoric Skulls.—Dr. H. Bellamy Gardner will give a Casual Communication on Variations in the Atmospheric Pressure, and their Influence upon the Inhalation of Anæsthetics.

TUESDAY, FEBRUARY 23rd.

THERAPEUTICAL SOCIETY in the Apothecaries' Hall at 4 p.m. (1) Dr. J. Burnet on Ichthoform and Ichthorgan: An Account of their Therapeutic Applications. (2) W. McAdam Eccles on Some Remarks respecting Trusses and their Use.

Vacancies.

Birmingham and Midland Eye Hospital.—House Surgeon, Salary £75 per annum. Applications to the Chairman of the Medical Board on or before Monday February 29th. Any further information may be obtained on application to the Secretary. By order, J. Cranmer Gell, Secretary, Secretary's Office, Church Street, Birmingham, February 13th, 1904.

Bradford Children's Hospital.—House Surgeon, Salary £100, with board, residence, and washing. Applications to C. V. Woodcock, Secretary, Bradford.

Cheltenham General Hospital.—Junior House Surgeon, Salary £70 per annum, with board, lodging, and washing. Applications to H. T. Carrington.

City of Sheffield.—Second Assistant Medical Officer, Salary £150 per annum, with board, lodging, and attendance. Applications to H. Sayer, Town Clerk, Town Clerk's Office, Town Hall, Sheffield.

Civil Service Commission.—Forthcoming Examination. Junior Assistant in the Department of the War Office Chemist, Woolwich. Applications to the Secretary, Civil Service Commission, Burlington Gardens, London, W. (See Advt.).

Clayton Hospital and Wakefield General Dispensary.—Junior House Surgeon, Salary £80 per annum, with board, lodgings, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

County Council of Middlesex.—Medical Officer of Health, Salary £700 per annum. Applications to Richd. Nicholson, Guildhall, Westminster, S.W. (See Advt.).

Gesto Hospital, Skye.—Resident Medical Officer, Salary £200 per annum, with furnished house, coals, light, and taxes. Applications to the Secretary, J. Simpson, North of Scotland Bank, Limited, Portree, Skye.

Joint Counties Asylum, Carmarthen.—Junior Assistant Medical Officer, Salary £150 per annum, with board, furnished apartments, and washing. Applications to Dr. Goodall, Medical Superintendent, The Asylum, Carmarthen.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medica Officer, Salary £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Lincoln General Dispensary.—Resident Male Medical Officer, Salary £150 per annum, with furnished apartments, fire, and gas provided. Applications to William Dean, Secretary, Board Room, Lincoln.

Roscommon Union.—Medical Officer of the Ballyleague Dispensary District, Salary £100 per annum. Applications to T. J. O'Keeffe. (See Advt.).

Royal Albert Edward Infirmary and Dispensary, Wigan.—Junior House Surgeon, Salary £80 per annum, with board, apartments, and washing. Applications to W. M. Taberner, General Superintendent and Secretary.

Royal Surrey County Hospital, Guildford.—Resident House Surgeon, Salary £100 per annum, with board, residence, and laundry. Applications to the Hon. Secretary.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant-Medical Officer, Salary £140 per annum, with board, &c. Applications to the Medical Superintendent.

West Riding Asylum, Wadsley, near Sheffield.—Fouth Assistant-Medical Officer, Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.

Appointments.

AWDRY, WALTER ROBERT, M.B., Durh., M.R.C.S., Honorary Surgeon to the Berkeley Hospital.

BATTEN, R. WINTERBOTHAM, M.D., F.R.C.P.Lond., M.R.C.S., Honorary Consulting Physician to the Berkeley Hospital.

BOWES, T. A., M.D. Cantab., Certifying Surgeon under the Factory Act for the Herne Bay District of the county of Kent.

FLEMING, R. J., M.D., House Surgeon to the Richmond, Whitworth, and Hardwicke Hospitals.

GRANT, L., L.D., M.S.Edin., Certifying Surgeon under the Factory Act for the Ballachulish District of the county of Argyll.

HEDLEY, A. S., M.B., B.S.Durh., Certifying Surgeon under the Factory Act for the Rothbury District of the county of Northumberland.

LANCASTER, ERNEST LE CRONIER, B.A., M.B., B.Ch.Oxon., M.R.C.S. Eng., Physician to the Swansea General and Eye Hospital.

LEE, DR. R. H., elected House Physician to the Richmond, Withworth and Hardwicke Hospitals.

MILWARD, F. VICTOR, M.B., B.C.Cantab., F.R.C.S.Eng., Medical Referee under the Workmen's Compensation Act for Birmingham, Bromsgrove, Redditch, and Solihull.

NUTHALL, A. W., F.R.C.S.Eng., Surgeon to out-patients to the Birmingham and Midland Free Hospital for Sick Children.

SALOMON, HENRY, M.D.Boston, L.R.C.P., L.R.C.S Edin., L.F.P.S. Glasg., Medical Officer to the Leicester Dispensary.

WILSON, J. CLARK, M.D., C.M.Edin., D.P.H.Camb., Pathologist to the Friedenheim Hospital, Upper Avenue Road. N.W.

Births.

BARTHOLEMEW.—On February 9th, at Cranbrook, Lansdowne Road, Aldershot, the wife of Captain E. Urquhart Bartholemew, Royal Army Medical Corps (Militia), of a son.

CAMERON.—On February 10th, at 9, Elms Road, Clapham Common, London, S.W., the wife of Albert Cameron, M.B., C.M., of a son.

COLMAN.—On February 11th, at 5, Home Terrace, Broughty Ferry, N.B., the wife of Horace C. Colman, M.D., of a son.

SOLLY.—On February 7th, at Strathlea, Harrogate, the wife of Ernest Solly, M.B., F.R.C.S., of a daughter.

Marriages.

BRIDGE—DAVIS.—On February 11th, at St. Matthew's Church, Ealing, John Crosthwaite Bridge, M.R.C.S., L.R.C.P., son of the late Rev. J. H. Bridge, vicar of Mucking, Essex, to Bessie Coleridge Davis, eldest daughter of the late Gateward Coleridge Davis, barrister-at-law, Inner Temple.

CAMERON—MACKINNON.—On February 11th, at the Parish Church, Welwyn, Herts, by the Rev, P. M. Wathen, rector, Captain Kenneth M. Cameron, R.A.M.C., to Norah Charlotte, second daughter of the late Walter Carr Mackinnon, 87th Regiment and 3rd Buffs.

Deaths.

BRIDGE.—On Fedruary 10th, at 49, Lissenden Mansions, London, N.W., Emily Sarah, widow of the late Alexander Bridge, M.D., M.R.C.P., of Argyll Place, W., aged 82.

The Medical Press and Circular.

Original Communications.

PROGNOSIS IN HEART DISEASE. (a)

By JAMES BARR, M.D., F.R.C.P.,

President, Liverpool Medical Institution; Senior Physician, Liverpool Royal Infirmary; and Lecturer on Clinical Medicine, Liverpool University.

(*Concluded from page* 169.)

Mitral Stenosis.—This is a lesion which usually commences very early in life as the result of rheumatic endocarditis, or of chorea, and progresses very slowly. It is much more common in females than in males, as they are more emotional, have more active thyroids, and consequently are more liable to palpitation with straining and forcible impact of the mitral cusps. This leads to sub-endothelial proliferation of the connective tissue, with subsequent scarring, contraction, and narrowing of the orifice. If the lesion starts in early childhood, it is likely to end fatally within ten or fifteen years; but if it begin after puberty, when the body is fairly developed, the patient may live to forty or fifty years of age, enjoy fairly good health, and bear a large family, though this is the lesion of all others most seriously affected by gestation. If there be a loud auricular systolic murmur, a regular pulse, about 80, of fairly good volume and moderate tension, and no evidence of failure of the right side of the heart, the prognosis is good. On the other hand, if the orifice is much contracted, the auricle dilated, perhaps no murmur at the mitral orifice, the pulse small, irregular in force and rhythm, infrequent, and only relatively high tension, a diastolic murmur at the pulmonic orifice, dilated right side of the heart with incompetency of the tricuspid valve, and a large pulsating liver, the prognosis is very grave. They are usually patched up for a time by rest, digitalin, strychnine, and nitro-glycerine, but under any stress or strain they break down and, after a few years' invalid life, succumb. Many patients in the early stage of this affection, if they happen to come under the care of an energetic therapeutist, scarcely get a fair chance; they are practically poisoned with digitalis, which raises the already far too high blood pressure, contracts an already too small ventricle, and further strains the mitral cusps and hastens the progress of the mischief. At this stage the patients require moderate exercise, a dry diet, and, if any medicine be necessary, it must be something like nitro-glycerine, which lessens the arterial blood pressure, allows a greater accumulation of blood in the systemic circuit, and lessens that in the pulmonic system. Patients suffering from advanced mitral stenosis are specially liable to embolism in the left middle cerebral artery from soft clots formed in the auricle. On the other hand, those suffering from infective endocarditis are more liable to infarcts in the spleen and kidneys. I look upon mitral stenosis as a lesion very amenable to treatment if intelligently dealt with during all its stages, but still, withal, a very serious affection, second only to aortic incompetency, not only from its effect in shortening life, but also from its crippling effects on the whole organism. Owing to the high arterial blood pressure, there is no anasarca until a late stage, when cardiac failure occurs.

Ascites frequently precedes the œdema of the lower extremities, and when there is also tricuspid stenosis, pleural effusion is not at all uncommon. Occasionally there is mitral stenosis following granular kidneys, but in such cases the contraction of the orifice is never very great, and the prognosis depends more on the renal affection than on the cardiac.

Mitral Stenosis accompanied by Mitral Incompetence.—The puckering of the mitral cusps and thickened edges often causes a buttonhole opening in the centre of a diaphragm, or at the end of a funnel-shaped orifice. This not only causes mitral obstruction but, being permanently open, allows of more or less free regurgitation. In advanced cases, the orifice may be very narrow, in some instances not larger than would admit a lead pencil, and consequently the ventricular systolic murmur may be very loud and musical, this being an exception to the dictum that the louder the murmur the less serious the lesion. In many of these cases the auricle is so much dilated that it fails to produce an auricular systolic murmur, hence many competent observers, who depend too much on murmurs in their diagnosis, fail to recognise the obstructive lesion, and treat such cases as those of pure mitral incompetency. Probably from these failures in diagnosis has arisen the impression in many minds that mitral incompetency is a more serious disease than mitral stenosis. In my opinion the regurgitation really adds nothing to the gravity of the case, and I hold that the man who cannot diagnose any cardiac lesion independently of the existence or non-existence of a murmur has only half learnt his work. In fact, he should have practically made his diagnosis before he puts his ear to the stethoscope. The prognosis in these cases largely depends on the extent of the lesion, which can be readily inferred from the secondary

(a) An Address delivered at the Southport Medical Society, January 27th, 1904.

conditions, such as the character of the pulse, the congestion and subsequent brown induration of the lungs, the competency of the pulmonic valves, the state of the right side of the heart, including the tricuspid valve, and the condition of the liver. I have seen some of these advanced cases last a few years as chronic invalids. The duration of these cases depends on the primary condition of stenosis, and is not practically affected by the incompetency. That the regurgitation is usually not great is shown by the arterial tension remaining relatively high, and there being no anasarca until there is cardiac failure.

Mitral Incompetency.—A pure mitral incompetency arising in early life from rheumatic endocarditis is, in my opinion, the most harmless valvular lesion. Moreover, it is the disease which is most benefited by digitalis, and therefore one to which the amateur physician can do least harm. A fellow-student of mine had mitral regurgitation of some standing, and has since been engaged in active practice for over thirty years. However, like any other lesion, there are different degrees of severity, and if you get marked hypertrophy with dilatation of the left ventricle, the chances of a long life are not great. This is more especially the case if the pulse be very irregular in force and rhythm, and there be a marked delay in its transmission; if there be frequent attacks of œdema of the lower extremities not very amenable to treatment; and if there be much dyspnœa and other pulmonary symptoms with secondary involvement of the right side of the heart.

Mitral incompetency arising in late adult life from degenerative changes in the aorta and coronary arteries, with dilatation of the left ventricle and enlargement of the mitral orifice, is a very serious lesion, and, although in the comparatively early stage is amenable to treatment, soon leads to cardiac failure and death. It is very difficult to put a time limit on this condition, but if life is to be prolonged, the patient must live at a low level, and avoid all stress and strain, whether physical or moral. The mitral regurgitation which frequently occurs in advanced chronic Bright's disease is merely an indication that the heart is giving way sooner than the vessels, and shows that the case is drawing to a close.

Aortic Obstruction.—This is generally looked upon as the least serious valvular defect—in fact, a very simple and usually harmless cardiac lesion—but it all depends on what is meant by aortic obstruction. If you look upon every case of an aortic systolic murmur due to slight thickening and roughening of the aortic cusps arising from an attack of rheumatic endocarditis as one of obstruction, then the prognosis may be considered extremely good. In such cases little or no hypertrophy is required, and the less the hypertrophy the more favourable the prognosis. If there be much obstruction from narrowing of the orifice, with perhaps two of the cusps fused together, the pulse long, slow, and infrequent, and the ventricle considerably hypertrophied, the prognosis becomes correspondingly more serious. But such cases may last for many years, even with an exceedingly small orifice, if the coronary arteries have escaped. The ventricle hypertrophies sufficiently to meet the obstruction, and remains healthy, provided the patient eschew alcohol, tea, coffee, and tobacco, and is not dosed with arsenic.

In cases of aortic systolic murmurs arising in advanced adult life and associated with atheroma or calcareous degeneration of the aorta, aortic cusps, and coronary arteries, the outlook is very bad. The clear ringing or clanging short, second sound indicative of a dilated and inelastic aorta is very ominous. If there be any suspicion of small aneurysms about the size of pigeons' eggs in the sinuses of Valsalva, you may be on the look-out for sudden death from rupture into the pericardial sac. The best that could happen in such a case would be aortic incompetency, but failing that, the blood pressure should be kept low. In cases of aneurysm of the thoracic aorta you not infrequently find that the aortic cusps become secondarily incompetent; but in cases of primary aortic incompetency due to rheumatic endocarditis you never get aneurysm. Hence I look upon the incompetence in such cases as a conservative lesion. In a case of aneurysm of the thoracic aorta I have seen all the pressure symptoms disappear and life much prolonged by such an occurrence. The greatest obstruction occurs in cases of granular kidneys, where, to use an Irishism, there is no aortic obstruction at all. Some time ago Dr. J. D. Wright and I had under our care a very clever and well-to-do engineer, but a rather cantankerous and obstinate patient. He was suffering from gouty kidneys, an aortic systolic murmur, an hypertrophied and powerful left ventricle with a mean blood pressure of over 250 millimetres of mercury. He had also peripheral neuritis with complete absence of the knee-jerks. I wished to make him a teetotaller and a vegetarian, but he strongly resented my treatment, and said that to hear Dr. Wright and myself talking, one would think that he never went to bed sober, but he could assure us that there was not a plainer-living man in Liverpool. I told him that was where the difference of opinion came in, and that I thought it would have been much better for him if he had gone occasionally to bed drunk, even with his boots on, rather than have continually lived at what I considered a high level. I plainly told him that if he did not lower the head of the liquid—to use an engineering term—the boiler would soon burst. However, he was not a man who was afraid to die, and while alive he was not going to be deprived of the pleasure of worrying his medical attendants. Under my treatment he declared he was "getting weaker and weaker every day," although I could point to the return and gradual improvement in the knee-jerks, and increased muscular power. Eventually he thought he would like other and perhaps more agreeable advice, and I gave him a letter to an eminent London physician who had done some good work on the diseases of the circulation. He evidently expressed his opinion very freely about me and my treatment, because I was very much amused to find in the letter which I received from my London friend that he took credit to himself for having patched up a quarrel between me and the patient. He did not know that when I give the best advice I can, I am not very particular whether the patient is pleased or not. If he does not take my advice that is his look-out, and he had better go to someone else. In impressing the patient with the great benefit which he had derived from my treatment, my friend told him, *inter alia*, that I had found albumin, now he could assure him there was not a trace. This was no doubt a fact, but in granular kidneys the presence or absence of albumin is of very little diagnostic and of no prognostic value. It is not what is excreted, but

the waste products which are retained that work the mischief. My friend relaxed my *régime* very considerably, of which the patient did not fail to apprise us when he returned. He soon afterwards got a slight apoplectic seizure. Our advice was again sought and followed. He recovered sufficiently to go a trip up the Mediterranean, a voyage which was undertaken by his own firm determination. He said the sea always did him good, and if he were going to die he might as well die there as anywhere else. He returned much improved, went to Llandudno, had another apoplectic seizure, and died.

Aortic Incompetency.—This is a lesion about which there have been very varied expressions of opinion. My own belief is that it is the most serious of all cardiac valvular lesions. On the other hand, Rosenstein, in Ziemssen's "Cyclopædia," says:—"The prognosis as regards the length of life and activity of the patient is more favourable in aortic insufficiency than in any other valvular disease. He may enjoy years of undisturbedly good health, as long as the increased force of the left ventricle suffices to prevent any stagnation of the circulation." I published a case where the disease lasted more than thirty-five years, during the whole of which time the man led an exceedingly active life, and for at least twenty years, as a School Board visitor, he walked fifteen to twenty miles or more daily. In this case the regurgitation was slight, the compensation good without much hypertrophy, and he led a very temperate life. The prognosis largely depends on the extent of the lesion. If the regurgitation is free and the dilated hypertrophy great, degenerative changes and cardiac failure set in early. For this reason the lesion occurring in the very young is certain to be progressive, and the life of the individual comparatively short. If it arise from an attack of rheumatic endocarditis about the age of 20 to 25, when the heart has attained its normal development, the prognosis is usually good. In such cases the lesion is not progressive, and if compensation do not require much hypertrophy, the patient may, with ordinary care, have a long life. The coronary arteries escape and the aorta retains its elasticity. These cases are easily separated from those arising from degenerative changes in the aorta by the slight but appreciable delay which takes place in the transmission of the pulse wave; hence I look upon this delay as a favourable omen. Healthy exercise is essential for the maintenance of healthy tissues, and every patient should avoid alcohol, tobacco, tea and coffee. When incompetency results from degenerative changes in the aorta the regurgitation is often very slight, and if the patient can be induced to lead a healthy life and avoid all gout-producing agents he may run the allotted span of life; but in many of these cases, before regurgitation has taken place and before advice is sought, the coronary arteries may be involved in the degenerative processes, and cardiac failure soon takes place. When compensation fails, the left ventricle gets more dilated and the mitral valve becomes incompetent, and you get much dyspnœa and œdema of the lower extremities, the end is not far off. This is the disease of all others where you get sudden death, and this is especially apt to occur where there are frequent intermissions in the pulse. There may have been no previous evidence of any failure of the left ventricle, but the coronary arteries are involved and the right side of the heart is often fatty; under any strain requiring increased oxidation it suddenly fails and the left side follows suit.

Aortic Incompetency, Mitral Stenosis, and Mitral Regurgitation.—This combination of lesions usually arises from rheumatic endocarditis. The mitral stenosis does not attain to any great degree of severity; the prognosis chiefly depends on the aortic lesion, and is practically always grave.

Angina pectoris is generally associated with aortic lesions. There are many cases of pseudo-angina, but in a true case, especially where the aorta is atheromatous, dilated, and walls thin, as indicated by a short, clear, ringing second sound, the patient is on the brink of a precipice.

Aortic and Mitral Lesions in the very Aged.—In people from 70 to 80 years of age or over, it is remarkable what loud, rasping, aortic systolic and diastolic, and mitral systolic murmurs are often heard without causing much, if any, cardiac disturbances. These murmurs are due to calcareous deposits in the valves, but the muscular structure is healthy, hence the freedom from symptoms, except those of senility.

Pulmonic Obstruction.—This lesion, we may say, is always congenital and usually associated with imperfect septum. It is only an exceptional case that reaches adult life.

Pulmonic Incompetence.—This lesion arises from high intra-pulmonary pressure due to mitral stenosis. It is very amenable to treatment; the prognosis is that of the mitral lesion.

Tricuspid Incompetence.—This is nearly always a secondary lesion, due to cardiac failure from some primary disease of the left side and often marks the terminal stage. However, it is not always so, and if the muscular structure be fairly healthy it is very amenable to treatment. Some eight months ago I was asked to see an old gentleman, the father of an eminent surgeon, who was supposed to be dying from heart disease. I found extensive arterial degeneration, aortic and mitral incompetency, congestion, and œdema of both lungs, very free tricuspid incompetency with a tender, pulsating, huge liver, which extended much below the level of the umbilicus. He recovered, and is now fairly well, but the murmurs are there, and the liver, though much reduced in size, still gives a very forcible pulsation. When the incompetency is due to acute strain from over-exertion or mountain climbing, the prognosis is, as a rule, good, if the patient gets over the immediate effects, both as to life and the complete recovery of the ventricle.

Tricuspid Stenosis.—This is frequently congenital, though it may be acquired from endocarditis in early life, and, I may say, is always associated with mitral stenosis. It is always less in extent than the mitral lesion, and I do not think adds much to the gravity of the latter affection. However, certain complications more readily occur, such as pleural effusion, ascites, pulmonary infarcts, and the venous sinuses in the heart are dilated. At present I know a child a few months old who has got well-marked tricuspid and mitral systolic murmurs; the child is perfectly well, and the murmurs were discovered accidentally. I daresay that the case will eventually end in mitral and tricuspid stenosis. As the child gets older the lesions may stunt her growth and development without giving rise to any cardiac symptoms.

Cardiac hypertrophy and dilatation, from

whatever cause arising, is sure to be followed by degeneration, and the greater the hypertrophy the earlier does failure take place.

Chronic Myocarditis and Fatty Degeneration of the Heart.—The diagnosis of these conditions is usually very difficult, unless the affection be far advanced, and then the prognosis is correspondingly serious. I differ from many writers in thinking that the right side of the heart is more frequently affected in an extreme degree than the left, and it is very fortunate for the patients when such is the case. At post-mortems I have often seen the right ventricle so fatty or fibroid that it must have been of very little use for years, and yet the patient had enjoyed fair health. I am inclined to think that, given a vigorous left ventricle and an active respiratory pump one might get on with only a simple reservoir on the right side. I know an old lady, now nearly eighty years of age, active and vigorous, who has had evidence of chronic myocarditis affecting chiefly the right side of the heart, such as arterio-sclerosis, irregular action of the heart, short, dull, right first sound, frequent doubling of first sound, and irregular pulse, for more than twenty years. Her mental energy often makes her undertake more work than she is capable of performing, and then she gets knocked over, has a bilious attack, &c., but with rest quickly recovers.

A STRANGE RESULT OF IODOFORM DRESSING. (*a*)

By H. MACNAUGHTON-JONES, M.D., &c.

THE local toxic effects of iodoform occasionally result in cutaneous conditions which are more or less serious, according to the extent of their invasion of the skin and their spread to other parts. The more common, which I have frequently seen, are general redness and swelling of the skin of the abdomen and down the thighs, sometimes extending from the trunk to the upper extremities, the eruption being very similar to that of scarlet fever. In several cases it was associated with a fine vesicular eruption, principally affecting the region of the wound. Other observers have had cases in which the vesiculation has extended into the deeper layers of the skin, resulting in considerable œdema, and, in some instances, in a sanguinolent effusion resembling superficial gangrene. (*b*)

A patient, æt. 30, on whom I recently operated for retroversion of the uterus by ventro-suspension, at the same time resecting an ovary, was progressing favourably until the third day after the operation. She then complained of irritation, and some smarting in the neighbourhood of the wound, which had been stitched with celloidinzwirn, a pad of moist sterilised 10 per cent. iodoform gauze being placed over it, and covered with coeletin. On raising the dressing, the nurse found some slight swelling and redness along the area of the incision. On the following day, when I examined the wound, the redness had extended to a considerable area, and the entire surface of the skin for a few inches at either side was vesicated. Attributing the condition to the iodoform, I had this removed, and the wound lightly sponged over with some weak formalin solution, dried, and dusted with dermatol (the subgallate of bismuth), covered with plain sterilised gauze and protected with coeletin. The distress continued, and on removing the dressing the next day I found several large vesicles, like those raised from an ordinary blister. One or two had burst, and the others were opened, and a quantity of serous fluid evacuated. There now appeared on the arms and hands some eczematous vesicles, and also a papillary eruption here and there, which was attended by great irritation. Much the same condition followed on the legs. The palms of the hands became red, and finally desquamated. Some three days later fresh vesicles appeared in the neighbourhood of the wound. There were no constitutional symptoms, and the range shows that there was but slight elevation of temperature on a few occasions, while the pulse remained normal. The skin healed by first intention, the suture being removed on the eleventh day.

Inquiring into the history of the case, it appeared that many years previously the patient had had an ulcer on the leg. This had been dressed with iodoform, when much the same effects had followed, the leg becoming œdematous, and a slough, extending some distance up, leaving an extensive cicatrix. The effects of the dressing were not discovered until after the toxic consequences had resulted. From her childhood she had suffered from an eczematous tendency, and there were symmetrical palmar patches of dry eczematous desquamation of long standing on the hands.

She left the Home perfectly well at the end of the fourth week, with only some remains of the eczematous condition in parts.

I have not seen the record of any case exactly similar to this, which is peculiar in the large blebs, somewhat like those of pemphigus, that appeared in the neighbourhood of the incision. One cannot help pondering on the consequences which would have followed in such a case had vaginal hysterectomy been performed, and the vagina tamponed with iodoform. I had the wound photographed when the vesiculation was at its height, but unfortunately, owing to the defective light, the photograph was not successful. One thing is clear—it is worth while inquiring, in any abdominal or pelvic operation in which iodoform is likely to be used, whether the patient has been subject to any cutaneous affection, and if so, to substitute another dressing for that of iodoform.

(*a*) Read at a meeting of the British Gynæcological Society, February 11th, 1904.

NOTE ON ONE OF THE CAUSES OF BLADDER IRRITATION IN GIRLS. (*a*)

By W. DUNNETT SPANTON, F.R.C.S., &c.,
Surgeon to the North Staffordshire Infirmary.

EVERY surgeon must have sometimes met with obscure cases of bladder irritation or cystitis in little girls, in which it has been difficult to assign a cause. Some instances have occurred in my practice which will tend to throw light on this subject, and are, therefore, I think, worth recording.

(*a*) Read at a meeting of the British Gynæcological Society, February 11th, 1904.

When a child is brought to the surgeon complaining of pain in the vesical region, frequent micturition and urethral irritation, the urine cloudy, perhaps containing a small quantity of blood and mucus, or muco-pus, without any constitutional disturbance, one generally would ascribe it to one of the following conditions :—

Diabetes, azoturia, calculus or other foreign body in the bladder, or urethra, or kidney, or possibly tubercle or malignant growth. The two last are rare and improbable.

Of course, the first thing to be done is to examine the condition of the urethra, and after examining the urine, to explore the bladder. The urethra may show signs of urethritis, but insufficient to account for all the symptoms ; the examination of the urine may indicate an excessive amount of uric acid, sugar, mucus, pus, blood, and possibly such irritating substances as oxalate of lime or triple phosphates.

If either oxaluria or azoturia exist, simple remedies will soon suffice to remove the irritation, but the presence of any inflammatory products will render this less likely. Then it will probably be found that the orifice of the urethra is sore and tender, and there may be discovered a tiny caruncle—and these will have to be eliminated from consideration. We then explore the bladder and find nothing ; when the puzzle as to the cause remains unsolved.

It is in such a case as this I found the wisdom of going more minutely into the question. And I will give a short account of three little patients in whom the same condition was found to exist, which will serve as an illustration :—

The first was a bright, healthy little girl about three years of age, who cried in micturition, which became very frequent, only small quantities of urine being passed each time. I found the urethral orifice tender and sore, and thinking this might be the sole cause of the trouble, prescribed some soothing application and gentle aperient simply. The urine was examined and found free from sugar and abnormal elements, but contained a little mucus, and a few blood corpuscles. The symptoms continued the same, so I passed a sound into the bladder under chloroform, suspecting there might be a calculus or some other foreign body. This revealed nothing ; but the urine which was next passed being examined, we found in it a shreddy-looking mass, with mucous cells, a few blood corpuscles, and mixed phosphates and urate of soda. Under the microscope the fluffy mass was shown to consist of an aggregation of woollen fibres entangled in mucus, and there were other woollen fibres also found free. Beyond a few blood corpuscles, crystals of mixed phosphates and amorphous urate of soda, nothing unusual was seen.

The next point was to discover how this irritating material had found its way into the bladder. I examined the child's under-garments, which consisted of thick woollen combinations, rather rough at the edges. The woollen fibres of these garments were carefully examined. I then came to the conclusion that, as the woollen fibres found in the urine exactly corresponded to those in the new set of "combinations" the child had been wearing, that the woollen material had chafed the urethra, some of the fibres had wormed themselves along it into the bladder, and so set up the irritation. When we remember the peculiar barbed edges of woollen fibres, it is quite easy to understand how they would travel up the urethra in the same way as an ear of grass or barley does ; and this also explains why the smooth fibres of flax or linen fail to do so. The garment was changed for a cashmere one, diluents were given freely to wash out the bladder, and in a few days every symptom had disappeared, and there has never been any since that time. I imagine that the sounding dislodged some of the woollen fibres, and as no more entered the bladder, this led to cure.

The next case was an older sister of the first, æt. about six. The symptoms in this child began in precisely the same manner. The urine on examination was found to contain woollen fibres, as in her sister's case, along with some mucus, and was of high specific gravity. The mother described it as containing "a long filmy substance," which proved to be wool fibres held together by bladder mucus. I did not, in the light of the former case, think it necessary to pass any instrument ; but merely changed the under-clothing, gave Contrexeville water freely, and very soon every symptom disappeared—never to return.

Some time afterwards, in 1901, another instance presenting similar features came under my notice. A merry little girl, æt. about five, was observed to show signs of irritation about the bladder, with frequent micturition and complaints of pain. There was no incontinence nor retention. I found her apparently in perfect general health. The symptoms were precisely similar to the former ones, but the urine was found overloaded with uric acid and urates, as well as containing the minute woollen threads. The note of urine examination was as follows :—Sp. gr. 1030, no albumin nor sugar, uric acid and oxalate of lime crystals, mucus and aggregations of fine woollen fibres.

The first thing to be done was to lessen the amount of nitrogenous food, to exchange the woollen garments next the skin for silk, and then give Contrexeville water freely. The child speedily got well, as in the former cases, and has had no trouble since.

It is often such little matters as these which, being overlooked, lead to the discredit of the surgeon, and it behoves the younger practitioner especially to bear in mind that such trivial causes may readily simulate more grave ones. They may then lead to a persistence of symptoms which, if unrelieved, may lay the foundation for gravel, for intractable cystitis, or possibly form, in a tuberculous subject, a focus for tubercle to attack—or, in other instances, a nucleus for stone. In fact, if we adopt Reginald Harrison's theory of the formation of calculi, it seems highly probable that threads entangled in the mucus of the bladder would readily lend themselves to such an evil purpose.

I daresay the same observations have been made by other surgeons, but no mention of them has ever come under my notice, and I have looked for them in the text-books in vain.

The following passed the Final in Medicine at the Hilary Term, 1904 :—Herbert St. M. Carter, Arthur W. Goldsmith, Wright Mitchell, Owen J. Parry-Edwards, Henry M. Crawford, John C. Hall, Wilfrid Thunder, William J. M'Iver, and David C. Pearson. M.B.—Robert Moore.

RUPTURE OF A TUBAL PREGNANCY

ON THE NINETEENTH DAY AFTER CONCEPTION, AND TEN DAYS AFTER THE UTERUS HAD BEEN CURETTED. (a)

By WILLIAM DUNCAN, M.D., F.R.C.S.,

Obstetric Physician to the Middlesex Hospital.

MRS. H., æt. 27, was married in 1900. She consulted me in October, 1901, for menorrhagia. The periods, which commenced at the age of 12, were quite regular (lasting four days) until the early part of 1901 (some months after marriage), when they began to increase in amount, with pain, the passage of clots, and a muco-purulent intermenstrual discharge. The patient was a healthy-looking but pale young lady of very active temperament. On examination, the uterus felt a little enlarged, was somewhat tender on palpation, was freely mobile and in normal position. Nothing abnormal could be felt in either the lateral or posterior fornices. Per speculum, the os uteri was eroded and some purulent discharge was seen exuding from it. I diagnosed fungous endometritis, and recommended that the uterus should be curetted. The patient went into a nursing home and, under anæsthesia, I dilated the cervix uteri up to No. 14 Hegar, and scraped away a very hypertrophied endometrium. The uterus, after having been swabbed out with liquor. iodi, was packed with iodoform gauze for forty-eight hours. At the end of that time the gauze was removed, and a vaginal douche of 1 in 4,000 solution of perchloride of mercury was ordered to be given night and morning whilst the patient remained in the home. (This is my usual method of treatment after curetting the uterus.) The patient made a perfectly uneventful recovery, and returned home well at the end of three weeks. I saw nothing more of her until the beginning of last November (1903), when she again consulted me for a recurrence of the menorrhagia. She then informed me that she had had a miscarriage at the third month, at Christmas, 1902, and that since that time the periods have been excessive and with clots. *Since the miscarriage she has never missed a period.* On examination, I found a similar condition of things to that present when she consulted me in 1901, except, perhaps, that the uterus was somewhat more bulky than on the former occasion, but nothing whatever abnormal was found in either fornix. As the next period was due in a few days it was decided that the curettage (which I again advised) should be deferred until a couple of days after the period had ceased. Accordingly, when this occurred, on November 14th, after a week's loss, I went down to the patient's home on November 16th, and, with the assistance of Dr. Gordon Hogg, of Ealing (under whose care the patient had placed herself, and to whose skill and unremitting attention the favourable termination of this most interesting case is largely due), I again curetted the uterus, removing, as on the former occasion, a very hypertrophied endometrium, but one which did not in the least raise in my mind the suspicion of its being a decidual lining. The patient progressed uninterruptedly well, having neither pain nor rise of temperature, until November 25th, when rupture took place.

At 9 p.m. that evening, Dr. Gordon Hogg rang me up on the telephone and asked me to go down and see the patient as she was bad. He told me that he paid his usual visit about 2 p.m. that afternoon, when the patient was, apparently, quite well, laughing and joking, and saying she would get up next day. On returning home from his round of professional visits at 7 p.m., he found a letter from the nurse asking him to send something to relieve the patient, who was complaining of pain at the chest and indigestion. Almost directly after reading the letter he received an urgent message asking him to go at once and see our patient. This he did, and on arrival he found her collapsed, pulseless, semi-conscious, and tossing about in bed, with gasping respiration. He at once injected strychnine hypodermically, and put hot bottles to the extremities in order to remedy the collapsed condition. As the patient's condition continued serious he, as I have mentioned, summoned me. On my arrival, soon after 10 p.m., I found the patient practically moribund, pulseless, blanched lips and gums very pale, and extremities cold. On palpating the abdomen, I found dulness in both flanks and over the hypogastrium. I also thought there was diminished resonance over the liver. It was evident that there was internal rupture of something, with hæmorrhage, also that abdominal section, unless associated with, or preceded by, transfusion, would be certainly fatal. Not having the necessary apparatus and instruments with me, I at once telephoned to my colleague, Mr. Pearce Gould, and, fortunately, found him at home, and got him to come out at once. Whilst waiting his arrival we prepared in readiness the operating table, also plenty of sterilised water. Mr. Gould arrived soon after midnight. The patient was at once placed on the table and skilfully put under the influence of ether by Dr. Robert Pitcairn Cockburn. Mr. Gould first started the infusion of saline fluid into the left submammary cellular tissue, and handed the care of this over to Dr Gordon Hogg, whilst he opened the left cephalic vein and performed intravenous transfusion (also of saline fluid). Immediately this transfusion was thoroughly started, I rapidly opened the abdomen, which was found full of liquid blood with some clots. The right uterine appendage was brought into view and proved to be normal, but when the left was drawn out there was seen to be a small, round perforation of the somewhat thickened tube near its uterine end (specimen shown). The broad ligament was quickly transfixed and tied with silk in the usual way, and tube and ovary removed. Most of the blood was sponged out of the abdominal cavity, which latter was also flushed with a lot of sterilised water, some of which was left inside. The abdominal wall was sewn up in three layers. Whilst this operation was proceeding, nearly two quarts of saline fluid had been injected (submammary and intravenous). After the operation, which lasted from twenty to thirty minutes, the patient was returned to bed, still in an extremely dangerous condition, although the pulse was faintly perceptible at the wrist. Hot bottles were applied, strychnine injected hypodermically, and an enema of brandy and beef-tea administered *per rectum*. When Mr. Gould and I left we could only give the relatives slight hope. Everything, of course, depended on whether the patient could be kept alive for the next few hours. We left her in Dr. Gordon Hogg's care, and the ultimate successful issue is greatly due to his unremitting attention.

(a) Read at a meeting of the British Gynæcological Society on February 11th, 1904.

At about 9 a.m. Dr. Hogg telephoned the welcome news that the patient was alive and conscious, that her pulse was better, her temperature normal, and she was able to take nourishment. The subsequent history can be related in a few words. The patient made an uneventful recovery, and is now (January 30th, 1904) quite well and getting about as usual.

Remarks.

This very interesting case presents several points for consideration :—

1. *The Duration of Pregnancy before Rupture took place.*—This can be accurately stated to be the nineteenth day, as after her recovery I went to see the patient in order to make sure of the date. She informed me that coitus took place on the Friday before her period commenced, namely, November 6th, and not for some time previous to then. Before questioning the patient I expected to hear that coitus had occurred on either of the two days which intervened between the cessation of the period and the curettage. This would have given eleven or twelve days before rupture. However, the patient was very positive that no coitus had taken place on either of those dates. As far as I can ascertain, there is only one other case recorded in which rupture of a tubal gestation took place as early as the nineteenth day. That is one reported by Mr. Rumley Dawson in the Obstetrical "Transactions" for the year 1898. (Vol. 40, p. 155.) In that case the rupture, which was near the uterine end of the tube, is said to have occurred on the fifteenth day. The patient was a multipara, and had not missed a period. Internal hæmorrhage was diagnosed, but no operation was performed, and the ruptured tubal gestation was only discovered post-mortem.

2. *As regards Diagnosis.*—When I first saw the patient there can be no question but that she was suffering from fungous endometritis, and although a tubal gestation was present *when I curetted the uterus*, seeing that it was only nine days old, and that the history was totally against pregnancy, I think it will be considered excusable my having failed to detect the slight enlargement of the left Fallopian tube, which must have been present when I examined the patient under anæsthesia before proceeding to curette the uterus. The more I see of cases of extra-uterine pregnancy, both in hospital and private practice, the less value do I know can be placed on the history of a patient having missed one or two periods. In many of these cases no such history can be obtained by the most careful questioning.

3. *When the Rupture took place.*—When Dr. Gordon Hogg rang me up on the telephone I confess I did not attach as much importance as I ought to have done to his statement that the patient, a few hours after he had seen her perfectly well, was collapsed and pulseless. I could not imagine anything having gone wrong with the pelvic organs ten days after curetting the uterus. However, on my arrival at the house and seeing the patient blanched (she was naturally pale), pulseless, and finding dulness in the flanks and over the abdomen, it was at once obvious that rupture of something had taken place with extensive hæmorrhage, which would ere long prove fatal unless operated upon. It seemed to me that the diagnosis lay between (*a*) rupture of a tubal gestation, and (*b*) perforation of a gastric ulcer with profuse bleeding. I leaned to the gastric ulcer view, as not only was the history completely against tubal pregnancy, but also I could not imagine myself failing to detect an enlarged tube; the fact also that on the afternoon of the accident the patient complained of indigestion and pain at the epigastrium helped to obscure the diagnosis.

4. Whatever the cause of the condition was, it was perfectly certain that the abdomen must be opened, as no one suffering from rupture of any internal organ with severe hæmorrhage should be allowed to die without an exploratory operation having been performed. In this case the patient was too bad to subject her to a severe operation without first (or, at any rate, simultaneously) transfusing her, and as I had not taken my transfusion apparatus with me, it was indeed fortunate to be within telephonic reach of skilled help and all the necessary instruments. This case teaches the lesson to always carry one's transfusion apparatus.

Lastly.—With regard to the parts removed, it will be seen from the specimen that the thickening of the Fallopian tube was comparatively slight, limited to the uterine half of the tube, and that the rupture took place near the uterus.

My friend, Dr. Victor Bonney (Obstetric Registrar and Tutor at the Middlesex Hospital), has made some excellent microscopical sections across the gestation sac, and a beautiful drawing of one of these is given. The section and the drawing made from it, which you see thrown on the screen with the epidiascope, very clearly show the gestation sac to be altogether away from the lumen of the Fallopian tube, and proves that what happens when a tubal gestation occurs is this :—"The minute embryo burrows through the epithelial lining of the tube into the muscular coat, where it develops, whilst the opening into the tube itself closes up again."

Pathological Report by Dr. Victor Bonney.

The specimen consisted of a Fallopian tube and attached ovary. The tube appeared normal to the naked eye, except at the junction of the isthmic and ampullary portions. Here was situated a small, hollow enlargement communicating with the outside by means of a clearly punched hole through which a small pencil might be passed. The cavity was principally in the tube wall, its outer wall being formed of thinly stretched tubal peritoneum, whilst its inner boundary was evidently in close connection with the tubal lumen, though whether it communicated with it was impossible to determine without cutting transversely across the tube at this point. On a transverse section being made across the tube on the uterine side of the punched-out aperture it was seen that the cavity was situated in the wall of the tube, and did not communicate with the tubal lumen at any point. Its outer wall was very thin, consisting practically of peritoneum only, but that towards the lumen of the tube was thicker, and contained muscle elements. The course of the lumen of the tube was marked in the inner wall of the cavity as a curved elevated ridge, much in the same way as the course of the acqueductus Fallopii is indicated on the inner and posterior walls of the tympanic cavity when the middle ear is opened up for dissection. The cavity contained clot and portions of chorionic villi.

Microscopically, the following appearances were found :—A considerable section of the tube and its contained gestation sac was removed, and the continuity of the specimen restored by sutures. This section was then prepared and cut in serial sections to the number of about 150. The appearances of individual sections were practically the same. The tubal lumen appeared intact, and was separated from the gestation sac by a well-marked muscular layer (capsularis) of considerable thickness. The plicæ

appeared perfect, as was also the case with the columnar epithelium covering them. The tube was empty. The gestation sac is situated in the outer part of the tube wall. It contained well-marked chorionic villi, with a distinct epithelium consisting of the two layers known as Langhans and syncytial respectively. In many parts, however, a much greater thickness of the syncytial layer was observable, and in those parts of the section where the villus was applied to the wall of the gestation sac these proliferating syncytial masses could be seen infiltrating the sac wall. The sac wall contained many spaces containing blood, part of which appeared to be surrounded by cells of embryonic origin. Many large cells resembling decidual cells were seen in the sac wall, but these were continuous with masses of syncytium, and in all probability they were of embryonic and not of maternal origin. There was, therefore, an absence of any structures which could be described as "decidual," and it is probable that such cells are strictly the derivative of the stroma cells of the endometrium, and therefore do not occur when the ovum is situated in the midst of muscular tissue as, in the absence of a subepithelial stroma, it appears to be in tubal gestation. To the absence of decidual cells is probably to be ascribed the rapidity with which a tubal gestation erodes the walls of the gestation sac and brings about early rupture. The specimen is of great interest, bearing out, as it does, the views put forward by all the modern German authorities, and lately epitomised in England by Dr. Russell Andrews, that in all cases the implantation of the tubal gestation is primarily in the muscular wall of the tube, and not, as was formerly supposed, in the surface of the tubal epithelium, and therefore within the tubal lumen.

Clinical Records.

NOTE ON A CYST SIMULATING FEMORAL HERNIA. (a)

By HERBERT SNOW, M.D.Lond., &c.,
Senior Surgeon, Cancer Hospital.

MRS. L. S., æt. 69, widow, a rather flabby, elderly woman, consulted me on December 10th last. She had worn a femoral truss on the left side for seven years, and now had on the right groin a globular elastic swelling of between three and four years' duration. It was of the size of a pigeon's egg, could not be reduced or diminished in bulk by pressure, and gave some impulse on coughing. She had never worn any truss for this. On removal of the left truss, a similar swelling became apparent, also with a certain degree of impulse on coughing. On pressure this diminished considerably in apparent size, though it did not wholly disappear. She considered that the truss had given her great relief.

An operation was advised. Upon incision it became apparent that the right tumour was a cyst containing about an ounce of clear, straw-coloured fluid, and with a narrow pedicle issuing from the femoral canal below Poupart's ligament in the usual site of femoral hernia. It contained nothing but this liquid. The wall resembled thickened peritoneum. It was slit up, and the interior carefully inspected. No aperture in the pedicle could be detected, and attempts to pass a probe failed. The cyst was excised and the pedicle ligatured. The woman made an uneventful recovery.

The left tumour was not interfered with, as no permission had been obtained to attack it, and the woman was quite satisfied with her truss. There can be no doubt that the condition was exactly identical. The impulse on coughing was found to disappear when the cyst was lifted up from its pedicle.

The right femoral cyst excised was evidently a peritoneal diverticulum, exactly similar in appearance and in average size to the common canal of Nuck cyst above Poupart's ligament. Mr. Cecil Leaf, who kindly assisted me at the little operation, suggested that a hernial sac had become nipped (and the lumen of the pedicle thus obliterated) by the edge of Gimbernat's ligament, the usual site of strangulation in hernia. The explanation is to some extent plausible, but we have no evidence that any intestine or omentum had ever been extruded, and the cysts were bilateral. I am inclined, therefore, to consider that the condition was of congenital origin.

I was not, before operating, satisfied that the impulse on coughing was sufficiently marked to be characteristic of hernia. But there certainly was a sufficiently marked impulse to deceive a hasty observer.

To find an exactly parallel condition to that presented by the canal of Nuck cyst, with which we are all familiar, at the external abdominal ring—not above but below Poupart's ligament, and with its pedicle issuing from the femoral canal—seems to me a very unusual state of things. I shall be glad to learn if any Fellow has encountered a similar case.

(a) Read at a meeting of the British Gynæcological Society, February 11th, 1904.

FATAL CASE OF PERTUSSIS IN AN INFANT OF TWELVE DAYS OLD.

Under the care of J. C. MCWALTER, M.A., D.P.H., M.D.Brux.

PERTUSSIS is still the opprobrium of the physician, and after eighty years of study and treatment of it the deaths per thousand from all causes have gone up from twenty-nine to thirty-six in London.

I think that the following case ought to be recorded, not because of any special treatment, for the child promptly succumbed, but because of the fact that the infant had never been outside the door of the house in which it was born, and because the disease had developed to the second stage, and proved fatal on the twelfth day from its birth.

On the ninth day the mother had noticed the infant feverish and restless, and with a slight catching cough. She called me in on the following evening, and I found mild catarrhal symptoms, with a temperature of 99·5° F. There appeared to me to be no reason for alarm, but the infant happened to give a cough which betrayed its malady. The mother could not readily be brought to believe in the possibility of its having whooping-cough, as she positively asserted that the infant had never been outside the house since its birth, and was not even christened, neither was there any whooping-cough in the house, which was in a respectable middle-class neighbourhood.

The child was worse next day, and Dr. Vivian, who was called in, agreed with the diagnosis. The violence of the cough seemed to rupture a blood-vessel in the brain, and such violent and uncontrollable convulsions set in that the infant died in a few hours.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXXIV.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

HAILEY SANATORIUM.

HAILEY SANATORIUM is situated on the picturesque slopes of the Chiltern Hills, on the borders of Oxfordshire, and with wide sweeping views along and across the Thames Valley. It is far removed from the habitations of mankind, but offers peculiar attractions for the lover of country life, and furnishes many advantages for the hygienic treatment of tuberculosis. In our former articles we have had occasion to indicate the great variations which exist in the structural conditions and manner of management of British sanatoria. To a very large extent the English treatment of consumption by institutional methods is yet in the experimental stage, and we are still in process of evolution.

Hailey Sanatorium is an interesting example of what may be accomplished by the châlet or so-called hut sytem.

Hailey offers three special features—isolated sleeping châlets, considerable natural shelter and variation in level.

The administrative portion consists of an old country

house which has manifestly been enlarged since first built. The dining-room is situated in the more modern portion. A kitchen annexe has been added. A few rooms are available for patients.

The front of the house faces east, and along this aspect is a large well-lit verandah which is a popular resort.

The sleeping châlets are of very simple construction. Each is a plain room raised on stanchions well above the ground, with eight windows which open in four directions, so that much adjustment is possible according to direction of wind or sunshine. Every châlet has a verandah or covered balcony. They are built of wood with air space between the outer and inner walls. A ventilator is fixed in each gable. The inner walls are varnished, and the outside painted. The furniture is necessarily limited and exceedingly simple. A stove affords warmth when required. Lamps are used for lighting. An electric light installation would prove of great service. Each châlet is in communication with the administrative block by an electric bell. Acetylene gas is used to light the dining-room and the large verandah in front of the house, and we were informed proves thoroughly satisfactory. We understand the cost of a châlet is about £45.

It is manifest that the châlet system, theoretically considered, has many advantages, but in actual practice even its keenest supporters are compelled to admit that it has serious drawbacks.

The ground at Hailey will allow of considerable addition being made to the little colony of châlets.

The estate comprises nearly seventy acres. A well-wooded portion is immediately adjacent to the house, and some distance away is an extensive upland. The subsoil is of gravel and thus is usually dry. Water is obtained from a deep well.

On one side of a large walled-in kitchen garden there is a long shelter having a south aspect and serving as an admirable liegehalle.

There are several good verandahs in the grounds, one forming an excellent "sun-trap."

In addition to pleasant lawns, gardens, and orchards, there is a small farm with dairy and good accommodation for poultry.

The old-fashioned ivy-clad elm trees, ornamental pines, rose trees and shrubberies not only add much to the picturesqueness of the grounds, but afford considerable shelter. The house is about 350 feet above sea-level, but the elevation of the grounds varies from 250 to 600 feet. There are various paths about the estate, and the surrounding country offers ample opportunities for graduated hill-climbing and carefully regulated walking exercise.

The sanitary arrangements are not elaborate, but appear to be effectual: earth closets are employed.

An adjacent cottage at the time of our visit was also being used for patients.

There is accommodation at present for about fourteen persons.

We had an opportunity of inspecting the sanatorium during a severe southerly gale. Dr. Charles Gaskell Higginson was acting as resident medical officer. The proprietors, we learn, are Dr. Charles Reinhardt and Dr. Frank Fowler, and the former acts as visiting physician.

Stourfield Park Sanatorium at Pokesdown, near Bournemouth, which we described in a former number (MEDICAL PRESS AND CIRCULAR, January 20th, 1904), is conducted by the same proprietors.

The sanatorium appears to be conducted on sound hygienic lines. The food is good and well served. There is a matron, nursing staff, and moderately large retinue of servants.

The rules are reasonable and were apparently, at the time of our visit, well and wisely enforced. The following are selections from the "Rules for Patients":—

"Patients (unless the doctor advises otherwise) rise at 8 a.m., and retire at 9 p.m.; all lights to be out by 10 p.m.

"Silence hours are from 12.30 to 3.30 and from 6 to 7 p.m. All patients should rest in silence. An hour's rest after each meal is usually advisable.

"Patients must not congregate in each other's châlets, nor in the public rooms, nor visit patients who are confined to bed, without permission."

The terms are four to five guineas weekly, according to accommodation, but some patients can be taken at three guineas. "The fees are inclusive of everything except personal laundry and alcohol, but patients whose condition renders it necessary to have meals served in their rooms are charged one guinea a week extra; and if a special nurse is needed, her fees and board must be paid for by the patient."

The postal address is Hailey Sanatorium, Ipsden, Wallingford. Telegrams should be addressed "Sanatorium, Ipsden." Goring and Wallingford Stations on the Great Western system are each about four and a half miles distant.

THE IPSDEN SUBSCRIPTION SANATORIUM.

Adjacent to Hailey there has recently been opened by the same proprietors a small sanatorium on the châlet system for patients of limited means. The châlets are of the type above described. A small bungalow serves as administrative block. It was intended to develop an industrial colony for consumptives, but it is found that the cases received are generally more or less unsuited for work or so untrained as to be useless for poultry farming, pheasant rearing, bee-keeping, or such duties as it was hoped might have given opportunity for the learning of the conduct of some form of useful out-door employment. It was originally intended that only incipient cases should be admitted. A medical certificate is necessary, and patients are obliged to conform to special rules. Among those the following may be quoted:—

"Patients (unless the doctor advises otherwise) rise at 8 a.m., and retire at 9 p.m. All lights to be out by 9.30.

"No alcoholic drink must be taken unless specially ordered by the doctor.

"Smoking is forbidden in the bungalow or châlets.

"Patients are expected to assist in the performance of household duties, the making of their beds, the cleaning of the bungalows and châlets, or work on the farm or gardens attached to Hailey Sanatorium, at the direction of the doctor."

The charges range from 32s. to two guineas per week, the lower fee being accepted for patients sent by municipalities and charitable societies.

The work at the Hailey and Ipsden Sanatoria furnishes instructive object-lessons, and the important experiments here proceeding are deserving of sympathetic criticism and careful observation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE MIDWIVES BOARD.

AT an ordinary Council, held on February 11th, the following important report on the Central Midwives Board was received and entered on the minutes:—

Mr. President and Gentleman,—I have the honour to present to you a short statement of the work of the Central Midwives Board during the past year. Twenty-two meetings have been held, and also many other meetings of Committees which were duly appointed by the Board. The first meeting of the Board was held on December 11th, 1902, and the last meeting took place on January 28th, 1904.

The preliminary business consisted in framing rules in accordance with Section III of the Midwives Act of 1902, and this important work occupied many meetings and caused considerable discussion. As soon as the report of the majority of the Board was completed it was forwarded to the Privy Council, together with another report prepared by a minority of the Board.

The present rules sanctioned by the Privy Council are the outcome of these two reports, and they are arranged in the following sections: (1) Rules regulating the proceedings of the Central Midwives Board. (2) The conditions of admission to the roll of midwives and the issue of certificates. (3) The course of training and the conduct of examinations. (4) The admission to the roll of women already in practice as

midwives at the passing of the Act. (5) The supervision and restriction within due limits of the practice of midwives. (6) The conditions under which midwives may be suspended from practice.

The attention of the Board was next directed to the preparation of other important details: (1) Suggestions to county and county borough councils in reference to the duties assigned to them under the Midwives Act. (2) Special rules of procedure for the removal of a name from the roll and the cancelling of a certificate. (3) Other rules of procedure respecting the restoration to the roll of a name previously removed.

The first roll of midwives was opened in November, 1903, and it records the names of the midwives who have been accepted by the Board under Section II of the Midwives Act. The following table indicates the number of midwives certified up to date:—

Women holding certificates from Institutions specified in Section II of the Midwives Act.	London Obstetrical Society	468
	Rotunda	27
	Coombe	1
Women holding certificates from bodies not specified in Section II but approved by the Board.	Queen Charlotte's Hospital	26
	St. Mary's Hospital, Manchester	22
	Glasgow Maternity Hospital	19
	Liverpool Lying-in Hospital	3
	City of London Lying-in Hospital	1
	Edinburgh Royal Maternity	1
	Salvation Army Maternity	2
	Manchester Southern and Maternity Hospital	—
	British Lying-in Hospital	—
Women certified as having been in *bonâ-fide* practice at least one year before July 1st, 1902.		1,079
Total certified		1,649

The regulations respecting the course of training and the conduct of examinations have not yet been completed. The following training institutions have been already accepted by the Board under Section C of the Rules:—

Queen Charlotte's Lying-in Hospital; Liverpool Ladies' Charity and Lying-in Hospital; Manchester Southern and Maternity Hospital; British Lying-in Hospital; Newcastle-on-Tyne Lying-in Hospital; General Lying-in Hospital, Lambeth; Glasgow Maternity Hospital; Dundee Maternity Hospital; District Nursing Association, Cheltenham; Maternity Charity and District Nurses' Home, Plaistow; National Maternity Hospital, Dublin; Edinburgh Royal Maternity Hospital; City of London Lying-in Hospital.

An unforeseen difficulty has recently arisen between the Irish training institutions and the Central Midwives Board respecting the certificates which must be produced before a candidate can be admitted to the Board examination. The rules under Section C make it compulsory that every woman shall have personally conducted twenty labours, and also nursed twenty lying-in women during ten days following labour.

On behalf of the hospitals, such as the Rotunda and the Coombe, in Dublin, it is stated that the medical staff of these institutions are unable to arrange that every midwife pupil should personally attend twenty cases of labour, as this would necessitate doubling the size of the hospitals and increasing the number of patients. It is also equally impossible to enable every midwife pupil to nurse twenty patients for ten days following labour, as nearly all the women leave the hospital on the eighth day and refuse to remain longer, even when the medical officers are anxious to detain them.

Now these regulations are scarcely fair to the Irish midwifery institutions, and a solution of the difficulty could easily be secured (1) by a modification of the regulations of admission to the examination; or (2) by accepting the six months' training in the wards of the hospitals, and the long course of instruction conducted by the staff, as equivalent to the three months' midwifery tutelage required by the Central Midwives Board.

At a recent meeting of the Board two important and conciliatory communications were read from the Irish hospitals, but the majority of the Board declined to consider any alteration of the existing rules; and, therefore, it is probable the matter will be referred for the decision of the Privy Council.

The appointment throughout the country of local bodies for carrying out the Midwives Act is a very hopeful and practical method, but up to the present time very little has been reported to the Central Midwives Board to indicate the progress of the work. The supervision of midwives is everywhere in the hands of local supervising authorities; but it is quite certain that effectual supervision and the successful operation of this Act must in a great measure depend upon the co-operation and assistance of the medical men practising within the area.

I am, Mr. President and Gentlemen,
Yours very faithfully,
JOHN WARD COUSINS.

British Health Resorts.

CORNWALL AS A WINTER HEALTH RESORT.

To many a British health wanderer in the sunny regions of Southern France or the dry desert districts of Egypt, the homeland of Cornwall is a veritable *terra incognita*. It is undoubtedly the case that but few physicians have any accurate knowledge as to the advantages offered by Britain's south-western peninsula. Invalids and convalescents are often sent abroad when tastes and temperaments would have been better met by a sojourn at one of the stations on the Cornish Riviera. Ignorance and prejudice account for much of this neglect, but it must be remembered that until comparatively recent times the land of "Tre, Pol, and Pen" was to a very great extent inaccessible. Now, however, through the enterprise of the Great Western Railway, the Cornish littoral is being brought near to England's capital and other busy centres. In an attractive pamphlet just published by that company, entitled "The Cornish Riviera and its Claims as a Winter Health and Pleasure Resort," the peculiar attractions of the West are faithfully portrayed, and by means of meteorological reports, carefully expressed opinions of experienced physicians, and descriptions of the various resorts available medical men may secure directions and suggestions which should avail much in selecting a suitable winter station where out-door life may be obtained without the risk and discomforts of foreign residence.

Cornwall has long exercised a fascination over the artist and romancer, and the land, rich in legendary lore and crowded with traditions and superstitions of peculiar attractiveness, is still capable of exciting psychological conditions of an alleviating influence to the wearied body and harassed mind.

Cornwall is not only a convenient district for the enfeebled in body, but a desirable haven for the overworked, brain-fagged citizen and wearied student.

Our Western Riviera has long had its admirers, and medical men will not forget the high praise bestowed by such careful observers as Paris, T. Q. Couch, Sir Edward Sieveking, Sir Joseph Fayrer, and others. Among lay writers, such as Carew, Michael Drayton, Baring Gould, Norway, and many another, Cornwall has been a word around which an enthusiasm has clustered and found outlet in much charming literature.

The winter climate of Cornwall is peculiarly suited to the needs of many invalids, convalescents, and sufferers from various maladies, and for the feeble and aged it can offer altogether exceptional advantages.

The winter climate of the Cornish Riviera would appear to rival that of many of the most popular

FALMOUTH.

foreign health resorts in the matter of mildness. In equability it undoubtedly surpasses not a few of the most popular Continental stations.

A considerable amount of sunshine is enjoyed, protection from winds can be obtained, and usually sudden and violent alternations of temperature are avoided.

We cannot attempt to deal with the various places available for the health-seeker and pleasure-desiring visitor. We hope in a subsequent series of articles on British Health Stations to deal with the more important features of the individual resorts. At the present time Falmouth, the Lizard district, St. Ives, Penzance, and the neighbourhood of Mount's Bay, Newquay, and Fowey are, perhaps, the best-known centres, but with a little local enterprise there is no reason why many fresh localities should not be opened up. The Scilly Islands, the great flower-garden for London in the early days of the spring, might readily be developed into a British sanatorium.

With the influx of visitors, suitable hygienic hotels will come. The Great Western Railway already own the attractive Tregenna Castle Hotel, overlooking St. Ives.

It may be safely prophesied that in the near future Cornwall will be considered one of the most valuable recruiting grounds for the overworked, and probably the best of our winter districts for the infirm and ailing.

Medical men will do well to make themselves fully acquainted with the many merits of this new and easily accessible winter health and pleasure district of the Cornish Riviera.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting Held Thursday, February 11th, 1904.

Professor John W. Taylor, M.D., F.R.C.S., President, in the Chair.

Dr. William Duncan read notes of a case of

EARLY RUPTURE OF A TUBAL GESTATION,

nineteen days after conception and ten after the uterus had been curetted, which will be found under the head of "Original Communications," page 200.

Dr. Macnaughton-Jones made a supplementary report on a tubal cyst shown by him at the December meeting, in which there had been some question as to the nature of the hæmatocele and the relation of the blood sac to the tube. The patient had gone a fortnight past her period when he first saw her, and there was no suspicion of ectopic gestation; he operated a few days later and she got perfectly well. The specimen had since been carefully examined; there was no doubt as to the tubal gestation; as, though there were no products of gestation in the blood clot, chorionic villi were found in the section of the tube. The blood sac, with which alone at the operation he thought he was dealing, was completely surrounded by the layers of the broad ligament, but it now appeared that it was an ovarian sac that constituted the hæmatocele, the constituent parts of the ovary being completely destroyed. There was a communication between the ovarian sac and that of the ectopic gestation.

The President said that Dr. Duncan's paper and the beautiful demonstration he had given them of a tubal pregnancy, not in the lumen of the tube, but invading the muscular wall, were of extreme interest. In his own book he had described a case in which rupture followed almost immediately after dilatation and the use of the curette. It was most important in the clinical diagnosis to exclude extra-uterine pregnancy, before venturing upon that proceeding the effect of which, in some cases, had been to precipitate disaster.

Dr. Herbert Snow congratulated Dr. Duncan on the very successful issue of his case. Personally, he thought that curetting was not a procedure to be lightly undertaken, as there was always a risk of serious hæmorrhage, and that, by swabbing out the cavity of the uterus with a strong preparation of iodine, as good results could be obtained as by the most thorough use of the curette.

Mr. W. D. Spanton said that the issue of such cases as the one narrated seemed to him to depend very greatly on the length of the operation. Every minute was of importance. He therefore demurred to the use

of three layers of sutures, as one layer was, he thought, sufficient, and should occupy a minute at the most.

Mr. CHRISTOPHER MARTIN asked for further explanation of the separation of the gestation sac from the lumen of the tube by a distinct muscular layer; might there not have been a rupture of the muscle and of the lumen of the tube elsewhere, and not shown in the section?

Dr. H. C. POPE asked for the particulars of any discharge which had occurred before the operation for curetting.

Dr. DUNCAN, in reply, said that he entirely agreed with the President that there was danger in curetting if there was any likelihood of extra-uterine gestation. He did not consider that there was much risk in dilating and curetting the uterus and swabbing it out, or, as preferred by himself, pouring in tincture of iodine so as to wash out the entire cavity. Very little extra time was taken up by suturing in three layers; the entire proceeding need only take a couple of minutes or so. The section shown was not cut through the rupture, but the number of sections made proved that the gestation sac did not open into the lumen. When an ovum attached itself to the mucosa of the tube wall, it penetrated the mucous and muscular layers and its port of entry closed up behind it.

Dr. MACNAUGHTON-JONES showed an aseptic cap to cover the nose and mouth during operations which he had devised; it was very light and was supported on a spectacle frame and was, he thought, more suitable than other instruments of the kind. He then read some notes on

A STRANGE RESULT OF IODOFORM GAUZE DRESSING,

which will be found on page 198.

Dr. HERBERT SNOW read notes on

A CYST SIMULATING FEMORAL HERNIA,

which are to be found on page 202, under the heading of "Clinical Records."

Mr. W. D. SPANTON read a short paper on

WOOLLEN FIBRES AS A CAUSE OF IRRITATION OF THE BLADDER IN GIRLS,

which is given on page 198.

The PRESIDENT, after thanking Dr. Snow and Mr. Spanton for their interesting communications, proceeded to read his Inaugural Address on

THE DIMINISHING BIRTH-RATE: ITS TENDENCY, CAUSES, AND POSSIBLE REMEDIES,

which we hope to publish in our next issue.

A vote of thanks to the President for his masterful address was proposed by Dr. HEYWOOD SMITH, seconded by Dr. MACNAUGHTON-JONES, and carried with acclamation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

MEETING HELD FEBRUARY 12TH, 1904.

SIR JOHN MOORE, the President of the Section, delivered an Inaugural Address on the subject of

SOME PUBLIC HEALTH PROBLEMS IN IRELAND.

He instanced the dying out of opposition to the principle of compulsory notification of infectious disease as a substantial advance in preventive medicine. A second great advance has been the official recognition of diplomas in State Medicine or Public Health. As to the prevention of tuberculosis, he considered that some such scheme as the following should be carried out with the view of checking the awful ravages of consumption in Ireland—namely, I. The rise and spread of tuberculosis in the cottage homes of the peasantry and in town dwellings must be grappled with by—(1) Notification, which should be compulsory; (2) verification of the diagnosis by means of bacteriological examination of the sputum, &c.; (3) removal of the patients to "hospital," using the term in its fullest sense; (4) periodic inspection of the homes of the tuberculous; (5) periodic disinfection of those homes. II. The provision of "hospital accommodation" for (1) Early cases, with a view to cure; (2) advanced cases, to provide comfort for the dying, and to secure safety for the living. [The expression "hospital accommodation" should include "isolation hospitals," "sanatoria," "consumption wards," and hospices for the dying.] III. The vigorous and absolute segregation of tuberculous cases in workhouses, asylums, and other public institutions. IV. Education of the public in all matters relating to the prevention and management of pulmonary tuberculosis. V. Improvement of the housing of the working classes and of the very poor, especially in towns. Closely connected with the prevention of tuberculosis is the question of the housing of the working classes and of the very poor—a very burning question in Dublin of late years. Much has already been done in this city to mitigate the evil of overcrowding. "Old Dublin" is, in fact, disappearing, and with it typhus fever has well nigh ceased to exist. The President severely criticised the Poor-law system of Ireland, stigmatising the internal economy of the workhouses as a grave scandal and a national disgrace. He specified the lines upon which reform should go. In conclusion, he dwelt upon the very unsatisfactory state of what may be called "the Home Medical Service," the Poor-law Medical Service—particularly in relation to the sanitary organisation of the country. In Dublin, as throughout Ireland, the dispensary medical officers remain the medical officers of health for their respective districts, and he contended that this hard-worked, badly-requited body of public servants, whose efforts for the health and welfare of the community are often misunderstood, and seldom, if ever, appreciated, should be properly recompensed for their services under the Public Health Acts. If this is done, and if the suggestions for the betterment of the health of the people made by the local medical officers are carried out intelligently and in a generous spirit, the dawn of a brighter day for the Irish race will at last be near at hand.

Dr. R. B. MCVITTIE read a paper on

THE ATTITUDE OF THE PROFESSION TOWARDS MODERN EDUCATION, FROM A PHYSICAL AND MENTAL STANDPOINT,

in which he pointed out that the great progress made in Denmark, Sweden and Germany of late years was mainly due to the control exercised by the medical profession over primary education; that as man is a living and growing being, only those who had made a life study of physiology and biology were fit to be intrusted with this development, while, unfortunately, in these countries the only qualification which appeared necessary for what was called an educationalist was a knowledge of some antiquated classic, which, being purely abstract, tended more to arrest than to encourage orderly growth; that as the nerve fibres from the surface to the pyramidal cell are myelinated first, all true education must be first concrete, and that the abstract should be discouraged as much as possible till the period of adolescence is fully completed, as too early a development of the psychic processes diverted the nerve energy from the control of tissue formation, which is its natural function during the period of growth.

Lt.-Col. MCNEECE expressed his gratification at hearing the paper, and considered that if the principles implied in it could be practically carried out, it would be to our great advantage as a nation. He gave a personal instance of the distaste and nausea which the present system of education raised in the minds of school children, and the essentially different view of things which was taken on going to a foreign country.

Sir JOHN MOORE reminded Dr. McVittie that the Irish universities were moving towards improving education in the direction suggested by him; the Royal University had established a diploma in Education, and examined candidates for the qualification; Trinity College was moving on the same lines, and lately, a course of lectures was delivered there on the subject of Education. He instanced the kindergarten as an example of the attention which was now given to the teaching of the concrete as distinguished from the abstract. He also related instances in which he had personally seen the miserable conditions in which many of the children in Dublin were taught.

Dr. MCVITTIE, in reply, said he was greatly obliged

for the favour with which his paper had been received. He said that he did not sign a recent circular from London asking for the signatures of members of the profession with a view to having instruction in hygiene and temperance introduced into schools, as such instruction only meant more classes and more exhaustion of the nerve centres, which would bring a desire for stimulation. He said that in the schools in Sweden and Denmark the children were only allowed to stay in one class for about forty-five minutes; they then stood up and did exercises tending to correct the cramping from sitting down, after which they went out to the playground for some minutes. He also emphasised the necessity for children being medically examined two or three times a year.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held February 5th.

Dr. Seymour Taylor, President, in the Chair.

Dr. Samuel West read a paper on

SOME POINTS IN FUNCTIONAL ALBUMINURIA,

a full abstract of which was published in our issue of February 10th.

In the discussion that followed the President considered all such cases, provided that catheter specimens of the urine contained albumin, to be pathological, but urged the necessity for careful microscopical examination to supplement this evidence. The presence of tube casts, free blood, or an excess of desquamated renal epithelium rendered the diagnosis of renal disease imperative. One important point that required further observation was the length of time that might elapse in cases of renal disease after the appearance of albumin in the urine before signs of cardio-vascular disease manifested themselves. If signs of increased tension in the renal pulse, accentuation of the aortic second sound, and displacement downwards and outwards of the heart's apex beat were present, although the albuminuria might be fugitive, all such cases must be regarded as coming under the category of Bright's disease.

Dr. G. A. Sutherland believed the postural or orthostatic variety to be a definite form of functional albuminuria. In these cases albumin appeared in the urine soon after the patient assumed the erect position in the morning, and decreased in amount as the day went on. The patients were most frequently young adolescents who exhibited accompanying symptoms which were very definite, chiefly of the nature of general vaso-motor disturbance, and which might be best summed up under the term neurasthenia. There were none of the signs or symptoms of nephritic disease in these cases. The cardio-vascular system showed evidence of feeble circulation. The hands and feet were cold and dusky, the pulse was of low tension and small volume, the cardiac action weak, irregular, and rapid, the first sound was poor and a general condition of cardiac atony was present. The prognosis of this form of functional albuminuria was frequently based on the view that it was an early symptom of nephritis, but no uncomplicated case had ever been shown to develop into organic renal disease. All the classical symptoms of adult neurasthenia were reproduced in these cases, and he had found from experience that treatment of this underlying condition was productive of the best results.

Dr. E. A. Saunders agreed with the President as to the necessity for microscopical examination of the urine in every case. The presence of a few hyaline casts he did not consider of greater clinical significance than the occurrence of albumin itself, but if many casts were present, especially if these were of the granular variety, they might be taken as evidence of chronic kidney disease. In estimating the prognosis in cases of albuminuria in the apparently healthy he attached great importance to the age of the patient and the amount of the albumin. After thirty years of age the gravity of the condition increased with every year of life, and, speaking generally, the larger the amount of the albumin the more serious the prognosis became.

LARYNGOLOGICAL SOCIETY OF LONDON.

Meeting held Friday, February 5th, 1904.

Mr. J. Charters Symonds, Vice-President, in the Chair.

Dr. E. S. Yonge showed Professor Meyer's apparatus for demonstrating the laryngeal image and intra-laryngeal manipulations. The apparatus was examined by most of the members of the Society, and proved to be extremely suitable for the purposes mentioned. He also showed microscopical sections of bone and soft tissues from a case of early polypus. The sections showed that the subjacent bone was perfectly healthy, and that there were no signs of either caries or necrosis.

Mr. A. H. Burt showed a case of a man, æt. 49, with questionable mild glanders.

Dr. H. L. Lack showed (1) a case of malignant disease of the tonsils in which he had operated with good results; (2) a microscopical section of endothelioma of the maxillary antrum; (3) a microscopical section and patient showing endothelioma of the larynx; and (4) a specimen of large osteoma of the ethmoid, with nasal polypi.

Dr. F. Potter showed a case of recurring papilloma of the larynx.

Mr. A. Thorne showed (1) a case of immobile left vocal cord in a man, æt. 35; (2) a man, æt. 35, with severe paroxysmal pain starting from the larynx; and (3) a tumour of the right side of the larynx in a woman, æt. 45. This latter case gave rise to a fair amount of discussion, the general opinion of the Society being that the tumour was of tuberculous origin.

Mr. H. W. Carson showed a case of laryngeal ulceration in a phthisical patient for diagnosis.

Mr. R. Lake showed a case of subglottic thickening.

Dr. J. Donelan showed a youth with fractured septum, and a depressed nose improved by operation and paraffin injection.

Dr. Dundas Grant showed (1) a case of fixation of the vocal cord with extreme pain in swallowing in a female patient, æt. 45. The question was whether it was tuberculous perichondritis; (2) a case of chronic œdema of the larynx (shown previously) in a middle-aged woman—probably tertiary syphilitic infiltration—greatly improved under mercurial inunction; (3) a case of ulceration of the pharynx after cervical fistula and œdema of the right half of the larynx in a middle-aged woman. The question of specific perichondritis of the arytænoids was raised.

Dr. W. Hill showed a skiagram from a male, æt. 48, showing a pin which had been in the larynx for four and a half years, and which had been removed subsequently by lateral laryngotomy.

ULSTER MEDICAL SOCIETY.

Meeting held in the Medical Institute, Belfast, on February 18th.

Professor Lindsay in the Chair.

Dr. John M'Caw read a short paper on

PSEUDO-HYPERTROPHIC PARALYSIS,

and showed a case for which we hope to have space in our next issue.

The paper was discussed by Dr. Beatty, Dr. McQuitty, Dr. McKisack, and Professor Lindsay.

Dr. W. D. Donnan, Holywood, showed a specimen of intestinal sand. The patient was a middle-aged man of alcoholic habits. He complained of pains in the region of the liver, and Dr. Donnan, thinking of gall-stones, told his wife to watch the motions for a few days, with the result that this sand was found shortly after each attack of pain.

Dr. W. D. Donnan also read notes of a m teresting case of

ACUTE LYMPHATIC LEUCÆMIA.

The patient was a schoolboy, æt. 12, apparently typically healthy, one of a large and healthy family. Last Easter he came home from school in England with a slight rash on his chest, and, feeling a little

languid, Dr. Donnan was called to see him on April 28th and found him very anæmic, the tongue coated, the heart normal, the spleen just felt, and abundant petechial spots on the chest, but no lymphatic enlargements. On May 4th there were fresh spots, and the morning temperature was 100°. On May 12th he got Dr. Houston to take a blood count, and he found the red corpuscles to be 1,600,000, and the white 40,000; of the latter 99 per cent. were lymphocytes. On May 14th the spleen was distinctly larger. He was then seen by Sir Wm. Whitla in consultation. On May 15th both pulse and temperature rose, and severe epistaxis began, the spleen rapidly returning to its former size. There was intense pain in the left ear. On May 16th the temperature was 101° in the morning and 103° in the evening, and the pulse 160. On the evening of the 19th he became delirious and died next day. The interesting points to note are that the symptoms only became really acute six days before death, and that nothing indicated the serious nature of the illness till the blood count was made. The epistaxis was easily controlled by plugging, and death seemed to be due to an acute septicæmia.

Dr. HOUSTON said that he had notes of about sixty cases of pernicious anæmia which he had examined, and only four of them were of this rare form, lymphatic leucæmia. Of these four, two had no glandular enlargements; all four were under twenty years of age; all died within three months, and two within six weeks of the onset.

Professor Lorrain Smith, Dr. M'Caw, and Dr. Trimble also made remarks on the case.

Dr. J. GORMAN (Bangor) gave an account of intra-tracheal injections in the treatment of abscess of the lung, phthisis, asthma, and whooping-cough. He had used various drugs and media, but favoured menthol in olive oil. He read notes of a number of cases, one of which, a bad case of abscess of the lung, excited special interest. Dr. A. B. Mitchell, who had seen this case, admitted that he had considered it hopeless, and when Dr. Gorman had suggested the intra-tracheal injections, he had said that, at any rate, they could do no harm.

Dr. CECIL SHAW (to whose paper on the same subject read before the Ulster Medical Society several years ago Dr. Gorman had referred) said that he had found menthol one of the most useful drugs in affections of the upper respiratory tract.

Professor LINDSAY thought that while such treatment might be useful in some affections, such as abscess of the lung, it could not be of any real benefit in phthisis.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 21st, 1904.

TREATMENT OF INGROWING NAIL.

DR. MARTEL, a rising surgeon of one of the provincial hospitals, protests strongly against the classical method (avulsion) of treating that frequent but painful affection known as ingrowing nail. The operation as practised, he admitted, was not grave, necessitating the most local anæsthesia produced by refrigeration or cocaine, the latter being preferable, although frequently general anæsthesia might be preferred to either, as giving less trouble to the operator. It mattered little, however, which of the methods was employed, the chances of a rapid healing were very doubtful. In any case, the patient is obliged to keep his bed three weeks at least, and frequently one or two more weeks have to pass before he can walk with ease, and sometimes the new nail grows badly, and the toe assumes a deformed and unsightly aspect. In his opinion, the painful ulceration of the ingrowing nail is only an ordinary sore, caused by the irritating and continued presence of a foreign body under the edge of the nail, and by the difficulty of keeping that region in an antiseptic condition—two defective conditions which alone hinder the healing of the parts. Naturally, the suppression of the foreign body or the cause of the irritation would be obtained by the simple ablation of the nail if the avulsion were not so terribly painful, but that radical treatment is not even necessary. It suffices to suppress the pressure of the foreign body into the ulceration, and this is easily done by paring as thinly as possible the back of the nail with a piece of ordinary glass. Thus treated the nail can support pressure without affecting the edges; the foreign body remains, but its painful effect is suppressed; from this moment the treatment of the sore alone requires the attention of the surgeon.

For several years M. Martel has treated such cases as follows:—After paring the nail as already described, he makes the patient take a footbath, and then washes out the groove with a solution of corrosive sublimate (1 in 1,000) very gently, so as to avoid making the parts bleed; the nail is cut straight, and without sacrificing the angle, which will be found useful later on in lifting the nail above the ulceration. A very small quantity of iodoform is then placed in the wound with a few threads of iodoform gauze packed at the bottom of the groove, and all covered by a little zinc ointment. Beneath the angle of the nail a little plug of prepared agaric is inserted so as to separate the fungous edge from the nail. The fungosites are treated by the application of nitrate of lead. The operation is completed by a small compress of cotton-wool moistened with some antiseptic solution (boric acid), and finally a bandage. Immediately after the first dressing the patient finds himself much relieved, and can put on his shoe. On the second day the dressing is removed, and the sore found to be much less inflamed, while suppuration has ceased. The third dressing is made four or five days later. Generally only four or five dressings are needed. Compared with the classical treatment, this bloodless method affords a double advantage: economy of suffering and of time.

TREATMENT OF EPILEPSY.

Professor Toulouse, of the Villejuif Hospital, has been making experiments on the effect of salt (chloride of sodium) on the bromide treatment of epilepsy, and has come to the conclusion that by diminishing to almost suppression the daily amount of salt absorbed in the food of an individual, the bromides acted with greater intensity and at less doses. He submitted a certain number of patients having almost daily seizures to the treatment of hypochloridation, and found that they were brought much more quickly under the influence of the bromide treatment; the attacks became less frequent and less intense, while those allowed the ordinary diet improved much more slowly and required increasing doses of the bromide. The amount of salt absorbed normally per diem is about half an ounce. By reducing this quantity to one drachm, and finally to 20 grains a day, the physiological point of hypochloridation is attained, and this point may be maintained for months without great harm to the patient. While going through this period the patient need not take more than 15 grains of bromide of potassium three times a day. The cells, it would seem, deprived of chloride of sodium, showed more avidity for the bromides, which acted thus with extraordinary intensity. If symptoms of bromism appeared (pupils indolent to light, tongue loaded, general depression, face drawn, lower lip hanging), the bromide is suspended, a purgative enema given, and the patient put on milk, to which salt is added—a teaspoonful to a quart. Three or four days afterwards the treatment may be continued.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, February 20th, 1904.

Paroxysmal Tachycardia.

At the Gesellschaft Schlesinger demonstrated from drawings and photos. the anatomical and pathological conditions of a patient, æt. 57, who died of paroxysmal tachycardia, and who had suffered for the last ten years with severe typical attacks. It may be well to note that there was insufficiency of both the aorta and mitral valves. The attacks usually lasted about a minute, but were frequently repeated for an hour, and even days at a time. Though not severe, they were easily induced by cough, pressure, or other movement in the fauces. The pulsations were accelerated suddenly from 60 or 80 pulsations in a minute to 160 or 250 in a minute, which might as suddenly be reduced, by compression on the right vagus near the end of the attack, to its normal condition. The patient felt by this sudden fall that he had had a shock which he expressed as having passed through the entire body. On account of these attacks lasting unduly long, the patient was brought to hospital, where he died after one of the attacks.

The post-mortem revealed the right vagus firmly bound up in the thorax with fibrous and lymphatic tissue. Over the compressed portion of the nerve the neurine structure was atrophied and the true nerve cell gone, being displaced in some measure by interstitial tissue. There were portions of the nerve both below and above the compressed site whose section revealed a perfectly normal condition.

Winternitz, in criticising the case, recollected one similar having the paroxysmal tachycardia, of which he still retained sphygmographic tracings, but at the time had no opportunity of a post-mortem examination. He was persuaded then, and is now more convinced, that the case was one of severe pressure of the vagus. The pulse usually commenced to rise suddenly to great frequency, and just as suddenly fell to normal.

Should Infants' Food be Sterilised?

This is a question that many practitioners have had difficulty in replying to rationally, as the irrational opinion is the one usually forced upon us as to the orthodox food of a baby. This tyrannical opinion has had the charm broken by no less a personage than Behring himself, who avows that the food of infants is more dangerous and less digestible when sterilised than when the milk is supplied in a pure natural form. This is somewhat refreshing to know, and must relieve the minds of many a sceptic who never had any faith in boiled whisky, milk, or beer! Common sense should lead us to the conclusion that boiling is destroying the ferment necessary for the digestion of the proteid.

Sterilisation as a germicide is not always desirable, as a fluid perfectly inert when taken into the mouth meets and takes up those germs from the air which may not be the most healthy for the child. The milk, having no healthy resisting bacilli, is dominated by the worst germs that the child could be exposed to. This opinion of Behring's has been rapidly and very widely circulated by the lay papers, which seem rather jubilant over the affair, while some of the medical papers breathe heavily. The conversions are certainly not numerous at the present moment, as Escherich, Paltauf, and Fränkel are still resolute in holding to the sterilised idea, yet it is remarkable that the first shell comes from the midst of the Continental savants.

Experimental Physiology at High Elevations.

At the last Physiological Congress held in Turin in 1901 it was decided that a series of experiments should be carried out on the summits of some of the Alpine peaks. For this purpose Professor Mosso selected Mont Rosa for the site of his laboratory, but to secure success it was necessary to have the patronage of a lady of high degree, which was easily obtained in the person of the Queen Mother Margherita, who already possessed a hut on the mountain of seven rooms, double walled and surrounded with a fine terrace. The building has been greatly enlarged and fully equipped for the purpose of accurate observation. The hut is 5,500 metres above sea level, or 17,040 feet. The enthusiastic pioneer has along with him three of the profession of his own country as well as Professor Altwater, from Middletown, America, who is over sixty years of age and 90 kilos or 14 stone in weight.

One devotes his whole time to respiration, &c.; another to the muscles and fluids; while others are engaged on the circulation.

Foà finds when experimenting with dogs and guinea-pigs, that the rarefied air does not alter the condition of the blood as was generally supposed; the distribution of the blood to surface and interior is the most important. Mosso finds that the blood of dogs takes up only half the amount of oxygen at this elevation, as the air contains only one-half of that at sea level in the same volume. He finds less CO_2 in the blood of the dog in proportion to the height. From venesections performed it is found that the alkalinity of the blood varies between 36 and 44 per cent. This alkalinity is due more to barometric pressure than to the presence of oxygen, hydrogen, or other gases.

Moser's Polyvalent Serum.

Bokay, who has been experimenting with Moser's polyvalent serum for the scarlatinal streptococcus, records rapid and good results. Shortly after the injection the whole condition improves, the cerebral conditions disappear, the exanthemata fade, and the temperature falls 2·1 per cent. The necrotic state of the throat ceases and a healthy appearance returns. No bad effects have been observed, except a serum rash in 58 per cent. of the cases.

The Operating Theatres.

ST. BARTHOLOMEW'S HOSPITAL.

Appendicectomy during Pregnancy. — Mr. McAdam Eccles operated upon a woman, æt. 39, who had been admitted suffering from pain in the right iliac fossa. She gave a history of having been seized with violent pain in the lower part of the abdomen, and chiefly on the right side, in September, 1903, associated with vomiting and a raised temperature. She was kept in bed for three weeks. Up till then she had been menstruating regularly. Her last period was in the middle of October, 1903, since which time there had been no loss. Soon after Christmas, 1903, she was again attacked by similar pain, which had continued, but gradually became less until admission. On examination, there was no evidence of any ovarian mischief, and nothing could be palpated in the region of the appendix. The uterus was enlarged, as in the fourth month of pregnancy. Mr. Eccles decided to explore. He opened the abdomen by an incision about two and a half inches long, made through the anterior layer of the sheath of the right rectus muscle, some two fingers' breadth internal to the semilunar line; he then displaced the rectus inwards, and divided the posterior layer of its sheath behind the position of the displaced muscle, and after it the extra-peritoneal tissue and the peritoneum; there immediately presented the omentum containing a serous cyst the size of a cob-nut. This Mr. Eccles took to

indicate that there had been inflammation in its neighbourhood, producing some obstruction to the lymphatics of the omentum and the formation of the cyst. On drawing this aside the appendix came spontaneously into view, rather sharply kinked upon itself, and some four inches long. Its blind extremity was dilated to about four times its proper size, and was lying in juxtaposition with the side wall of the pregnant uterus. The tube was removed in the usual way, and the small stump buried beneath a covering of serous membrane to prevent it becoming adherent to the enlarging uterus. The cyst in the omentum was removed, and the parts returned within the abdomen. The aperture in the serous membrane and the posterior layer of the rectus sheath were closed by a series of interrupted sutures of fine silk, then the rectus muscle was replaced in position, and the anterior layer of its sheath similarly stitched; the skin and subcutaneous tissues were finally brought together by a series of silkworm-gut sutures, and the wound dressed with gauze and collodion.

The patient, who had double mitral disease as well as the abdominal trouble, took chloroform fairly well. She stood the operation excellently and exhibited no untoward signs whatever, having no indications of any threatening of miscarriage. Mr. Eccles stated that although the diagnosis could not be said to be certainly that of appendix inflammation, yet it was so suggestive that he deemed it advisable to explore, in spite of the fact that the woman was pregnant, and had a cardiac lesion. In fact, he was convinced that the condition of the pregnancy was a strong argument in favour of exploration, for there was a great probability that, seeing the patient had had two definite attacks of some inflammatory mischief, she was likely to be again subjected to it. Suppurative appendicitis in the course of pregnancy, he thought, was of the gravest import, particularly when the appendix hung over the brim of the pelvis, for then the side of the enlarged uterus might be a portion of the abscess wall, and abortion or miscarriage was extremely liable to occur, leading to a rapid diminution in the size of the uterus, and thus a tearing away of one part of the limiting wall of the abscess and the flooding of the peritoneum with pus. The operation in the quiescent period was, he pointed out, almost without risk, and placed the patient in a safe condition. Mr. Eccles believed that the incision which he had employed was the best, namely, that through the rectus sheath, with displacement of the muscle. True, it had the objection of rendering the operation a little more difficult from its internal position, but it had the great advantage in being practically safe from the after occurrence of a ventral hernia. This in such a case as the present one was a great desideratum.

A week after the operation the wound was completely healed, and the patient entirely free of pain.

GREAT NORTHERN HOSPITAL.

TWO CASES OF GASTRIC ULCER.—*First Case.*—Mr. PEYTON BEALE operated on a woman, æt. about 40, who had been under medical treatment at the hospital for three months for symptoms which led to a diagnosis of gastric ulcer. She had improved markedly for a fortnight, but directly any attempt was made to give her solid food she at once relapsed with intense localised epigastric pain, vomiting and repeated hæmorrhage. As these symptoms had recurred two or three times, and as further medical treatment appeared to be of no avail, and the patient was evidently losing ground, she was transferred to a surgical ward. The following operation was performed:—A skin incision about three inches long was made parallel to, and about half an inch below, the left costal margin, the incision beginning about the median line of the abdomen. The edges were retracted and the muscular and peritoneal layers incised in the same direction, but about half an inch below the skin incision. The anterior wall of the stomach being thus exposed, a hard lump, about the size of a florin, could be felt in it; this appeared to involve the mucous membrane and about one-half of the muscular wall, and was only felt when the stomach was pinched up between the finger and thumb. The anterior wall of the stomach, including the lump, was pulled out of the wound and a two inch incision made through the stomach wall about half an inch above the margin of the lump. It was then seen that there was a ragged ulcer about half an inch in diameter, with very hard and thickened edges. This was excised, together with the whole thickness of the stomach wall, with scissors, the incision commencing on the mucous aspect of the stomach. The aperture resulting from the excision of the ulcer was stitched up from within with interrupted sutures placed about one-eighth of an inch apart, then the original wound in the stomach wall was stitched up from the outside with continuous and interrupted silk sutures. During the performance of the operation the house surgeon kept a sufficient portion of the stomach outside the abdominal wound as to prevent any of its contents entering the peritoneal cavity. The abdominal wound was then closed in the usual manner, a small gauze drain being left in for the first twenty-four hours.

Second Case.—A young woman, æt. 20, was admitted with symptoms of ruptured gastric ulcer. There was a typical history of an ulcer extending over two years. Thirteen hours previous to admission she was suddenly seized with very intense pain and collapse, which clearly coincided with the rupture of the ulcer. An abdominal incision similar to that in the previous case was made, and the peritoneal cavity found full of the contents of the stomach, the ruptured ulcer being discovered without much difficulty on the posterior wall at the pyloric end of the viscus. A two inch incision was made through the anterior wall of the stomach, and the organ, together with as much of the peritoneal cavity as possible, was quickly washed out with large quantities of hot sterile water. The ulcer in this case was only about half an inch in diameter, the perforation being about a quarter of an inch. As in the previous case, the whole ulcer was excised with scissors from within, through the incision in the anterior wall, and its edges were rapidly sutured as before, the anterior stomach incision being afterwards stitched up. In this case a couple of large gauze drains were left in the abdominal wound to remain for two days, and the peritoneal cavity was left as full as possible of hot sterile water. Mr. Beale said that in all cases of gastric ulcer on which he had operated within the last two years, including chronic and ruptured, he had adopted this method of opening the stomach at some little distance from the ulcer, and then excising the latter including the thickness of the whole stomach wall, the edges being then stitched together. The advantages, he pointed out, of this method were that it could be done very quickly, that the stitches passed through healthy stomach wall, and that it involved comparatively very little pulling about of the organ. He said it was true that operating in this way involved the stitching up of two incisions in the stomach wall, but even this could be performed rapidly. It was necessary, he said, to feed the patient *per rectum* for three days, and he had found that on the fourth day there was no danger

in feeding the patient by the mouth with fluid food. Of course, it was unlikely that the sutured wounds in the stomach were absolutely watertight when they were stitched up, but they appeared to become so in about twenty-four hours. He considered it more important to carry out an operation of this kind quickly than to attempt to obtain an absolutely watertight junction.

In one of these cases, at least, it was certain that gastric juice was escaping into the peritoneal cavity when the wound was dressed twelve hours after operation, but its presence appeared to have no ill effects. Both patients did well.

WEDNESDAY, FEBRUARY 24, 1904.

STREET NOISES.

There are some influences in modern life to which it is extremely difficult to assign a definite place in the etiology of disease, and yet there can be no doubt that they exercise a highly deleterious effect both upon individuals and upon the public health. Noise is one of these influences. Everyone will agree that quiet is essential to the maintenance of that placidity of the nervous system which enables it to do its work to the greatest advantage. Many of the jars of modern life are harmful although none the less inevitable. Irritability of disposition, spasmodic activity of the nerve centres, continual tension—all of these conduce to early fatigue and rapid wearing out of the tissues. A train of evils follow in their wake. Sleeplessness is perhaps the worst. The working value of the citizen to the State, to say nothing of his own peace of mind, is greatly lowered. Cæsar wished for his counsellors calm, placid individuals.

"Let me have men about me that are fat;
Sleek-headed men, and such as sleep o' nights."

And Cæsar was right. The man that has his nervous system constantly on the stretch, "keyed-up," as the Americans call it, is the man who will break down when the big strain comes. Noise is perhaps one of the most potent factors in producing that irritability which denies men the power of doing their best work when young, and tends to the abrogation of the power of working at all soon after middle age. How far it may handicap even a genius is shown by the effect it had on such a concentrated worker as Carlyle. The exasperation caused to the sage by the Chelsea cocks is notorious, and the ebullitions of wrath that followed their incessant crowing have often been the subject of mirth among men of coarser temper than the author of "Sartor Resartus." But that they really prevented his turning out his masterpieces till he had constructed the sound-proof chamber in his house is an actual fact that no one doubts. So, too, with sleep. It is hardly worth stating so obvious a truism as that noise prevents sleep, and that without sound sleep no one is capable of sustained effort. Now noise is bad enough in itself, but its influence is far wider than the mere reflex it produces. A continuous noise may cease to ruffle the dispositions of those within its range; use makes one unconscious of it. The engineer of a ship no more notices the noise of his engines than he does the ticking of his watch; but he will wake in an instant if his engines stop. It is, then, not noise itself that is harmful, but unexpected noise. Perhaps what is even more distracting is the anticipation of noise, the uncertainty as to whether it will come or not. The strain of expecting the noise which is postponed is more trying than the actual sound when it does come, and the tension that is not relieved amounts to positive pain at times. The town dweller gets accustomed to a certain normal roar or hum in the atmosphere and takes but little notice of it; the cabs, the omnibuses, the carts go by in a continual stream, and he is not disturbed. There is a merciful compensatory mechanism somewhere in the cerebrum. But the cries of the street-hawker, the music of the barrel-organ, and the vociferations of the newsboy are different. These sounds come irregularly and sporadically, and frequently; none are necessary and all are of the most irritating type. The street hawkers' wares are visible to the eye without stentorian appeals to the ear being required to attract the customer; the clatter of the street organ is painful to all who have music in themselves and delights only the quidnunc urchin of the gutter; the contents bill of the newspaper is generally got up to make a sufficient impression on the senses without the hullabaloos of gamins who sell them being needed to confirm it. The wear and tear of town life already tax the resources of the nervous system to the uttermost, and it is high time that it should be relieved of a burden already almost too heavy to be borne. We sympathise sincerely with the desire of the County Council to put an end once and for all to all unnecessary cries and clatter by a by-law for the whole area of the Metropolis, and we think it a pity that the Home Secretary should have decided that it was better to leave the framing to these laws to the borough councils individually. As, however, the duty has been left to them we trust they will take the matter in hand without delay. The more stringent the by-law and the heavier the penalty (within reason) the better we shall be pleased. Kensington has already taken the matter in hand, and Paddington is proposing

to follow suit. Is it too much to hope the other borough councils will not lag behind, but make a determined effort to suppress an unnecessary evil that makes life unbearable for many and may even shorten it for not a few ?

TYPHOID FEVER AND MALARIA.

EVERY practitioner knows that there are few diseases so difficult of diagnosis as typhoid fever. Insidious in its onset, and rarely answering in any one case in more than a few of its features to the classical descriptions, there are at least half a dozen other conditions which one must bear in mind when giving an opinion early in the disease. Until its duration and some special characters distinguish it, it is very liable to be mistaken for influenza, and, on the other hand, diseases differing so enormously in pathology from it and from each other as general miliary tuberculosis and tuberculous meningitis have not seldom been mistaken for it. In this country luckily we have not, as a rule, to consider malaria as one of the diseases needing a differential diagnosis from typhoid fever. In the United States, however, there seems to be a very great difficulty in distinguishing them. Indeed, so notorious is this that at the last meeting of the American Medical Association a warm debate took place on the question whether in many parts of the continent what is described as "malaria," or simply "fever," is not in truth typhoid. It appears that taking the States as a whole, the Census returns furnished by the profession give malaria credit for half as many deaths as typhoid. On the other hand, a special Government Commission which inquired into the health of the army was unable to find any evidence that fatal malarial infection had occurred among soldiers in any part of the States. Again, the mortality-rate with which the profession at large charges malaria is entirely out of proportion to the rate as determined by hospital physicians. According to Dr. Fulton, of Baltimore, a critical observer, not one person a year dies of malaria in Maryland, although it is undoubtedly a considerable cause of disability in some parts of that State. In the same strain, Dr. Krauss, of Memphis, fixes the malarial mortality-rate in his own practice as low as 0·4 per cent. It is also noted that in Maryland, where examinations of the blood for the malarial parasite are regularly made by the health authorities, only in 5 per cent. of the specimens submitted has the diagnosis been confirmed. Under the circumstances there is much in favour of Osler's dictum that every continued fever not yielding in six or seven days to quinine should be regarded as typhoid, until it is definitely decided to be something else.

THE PLEA OF INSANITY.

THE old question as to who is the better judge of insanity—the lawyer or the medical man—was again to the fore in a case heard at the Oxford Assizes on the fourth of this month. The facts were very simple, and, indeed, were not seriously in dispute. The prisoner, Mr. Bond, was a gentleman who, after much hardship in early life, succeeded in educating himself and graduating with *éclat* at the University of Dublin. He took Holy Orders, held several responsible masterships in schools, and finally was appointed chaplain to a county lunatic asylum. This post he held for twenty-seven years, at the end of which time he retired of his own accord on accepting a living. Soon after this mental symptoms developed, and one day he was charged with committing an act of indecency with a little girl, a charge that the magistrates dismissed. He thereupon resigned his living, and went with his wife to live near Oxford. Since then other acts of the kind mentioned were charged against him, and eventually he found himself committed for trial at the Assizes. Now we admit that to the ordinary healthy man no crime is more revolting than that with which Mr. Bond was charged, and none raises so much indignation in one's breast. That, however, is not the point at issue. The question is—Does a man who has lived an upright, straightforward life, who has held honourable positions with credit to himself, who has won respect as a minister of religion for more than a quarter of a century, does such a man, we ask, in the evening of his days, fall into practices that would disgrace a guttersnipe, without serious cause ? If a man were the depraved degenerate that such acts would proclaim him, he could not have passed through a long life without giving evidence of the fact. In this case such evidence was lacking. The defending counsel called two alienists of the highest standing, who both swore that the prisoner was suffering from senile degenerative changes, for which there was abundant physical confirmation apart from the subjective symptoms of which the prisoner complained. There had been progressive numbness of the limbs for the previous eighteen months, attacks of giddiness, confusion of ideas, and loss of memory ; besides these the arteries showed degenerative changes in their walls. Will power was defective and uncontrollable, perverse sexual ideas came upon him from time to time. In fact, a clearer case of senile decay, physical and mental, could not be conceived. The judge, Mr. Justice Ridley, in his summing up, said that, with all respect for the medical witnesses, the question for the jury was—Did the prisoner know that the act was wrong at the time it was committed, or not ? In the latter case he had established his defence ; in the former he had not. Now, as it had been already admitted by the medical witnesses that the prisoner knew he was doing wrong and yet could not help it, this was tantamount to telling the jury what verdict they should give. They understood it evidently in that sense, and found the prisoner guilty. He was sentenced to six months' imprisonment with hard labour. There can, therefore, be no question as to what the judge himself thought of the case. Here is a clear issue. Mr. Justice Ridley doubtless felt himself bound by the Macnaughten rules, which laid down that the responsibility of the insane rested on the

appreciation of the rightness or wrongness of the particular act committed, and in this case the prisoner knew that he was doing wrong at the time. The medical witnesses were emphatic that he acted under an uncontrollable impulse, and that this want of control was part of, and resulted from, his pathological condition. Surely here was a case, if ever there was one, for the judge to exercise his discretion. But Mr. Justice Ridley entirely repudiated the idea that mere decay of faculties was evidence of insanity, or that a person suffering from senile decay was not responsible for his actions. On this view he signed what must practically be the death-warrant of the unfortunate prisoner. Two conclusions follow obviously from these facts. First, that Mr. Justice Ridley has the most crude notions of mental pathology. He thinks that because he has known a certain number of people who have shown eccentricities in their old age, and yet have remained responsible agents, that he understands the whole of that morbid condition which we call senile dementia. Secondly, that the rules laid down by the Lords after the Macnaughten case, although certainly an improvement on those that existed before, are far from meeting every case of insanity. The lawyer prides himself on knowing all that it is necessary to know of insanity because he has a good knowledge of things in general; the alienist doctor in his view is a crank who is perhaps a little tainted by contact with his patients; in fine, Mr. Justice Ridley summed the situation up concisely when the told the jury "to exercise their common sense as men of the world." This form of legal arrogance cannot be too strenuously resisted—for the sake of the victims who suffer from its presumption. A lawyer, have he never so much common sense as a man of the world, would not feel it within his province to decide if a patient were suffering from typhoid fever or acute tuberculosis; he would be glad to avail himself of the services of the man who had spent a lifetime in the study of the conditions, and to take his decision. For the same reason he should understand that the only person in the least capable of deciding whether or not a patient was suffering from senile dementia, or any other form of insanity, is the man who has made himself master of the manifestations of the brain in health and disease. An educated man does not lose "his common sense as a man of the world" because he happens to have studied the pathology of the human body, and it would be well if the lawyers were gifted with a sufficient sense of humour to see how egregiously they err when they pronounce opinions on subjects which they cannot in the least understand.

Notes on Current Topics.

The Royal Army Medical College.

Standing far apart from the ordinary run of opening addresses, and of interest alike in its occasion and its matter, was Sir William Taylor's welcome to the young Army medical officers just arrived at the Royal Army Medical College. There has been far too much running-down of the Army Medical Service in the past, and civilians have sometimes shown a tendency to contemn their brethren in the Service, as men of a lower professional standing than themselves. Such an attitude must have a strong and bad effect on the self-respect of medical officers, while at the same time it tends to deter the better class of young graduates from entering the Service. The Director-General is quite right in believing that he can do nothing of so much value to his Corps as make the young surgeons recognise that they should be proud to belong to it, and his address is eminently well calculated to that end. The progress of science owes far more to officers in the Government service than is usually admitted. In two great departments the pioneers during the last half century were Army medical men—in hygiene and tropical diseases. "The Army Medical School may well be proud of the world-wide fame which its first Professor of Military Hygiene earned for himself. Among the many reputations as hygienists which have since been earned there is no name so illustrious as that of Professor Parkes." And among Parkes' pupils there have been many who have well maintained the honours of the Service in the field of hygiene. In early days De Chaumont, and later Colonel Lane Notter, Colonel Firth, Colonel Davies, and Major Horrocks, are men of more than insular reputation. In the field of pathology almost our whole knowledge of trypanosomiasis is due to the Services, from Lewis' discovery of the flagellate in the blood of rats, to Colonel Bruce's recent researches on sleeping sickness in Uganda. It is superfluous to say anything of Major Ronald Ross. Of living pathologists there are none of greater eminence in England than Professor Wright and his successor Major Leishman. Sir William Taylor has done excellently in directing the attention of his recruits to such men as he has mentioned, for in their footsteps any man of science may be proud to walk.

More About Radium.

Almost every week fresh reports come to hand of the therapeutical applications of M. Curie's wonderful discovery. In our last number a *résumé* of some of the results so far obtained was published by Dr. Walsh in his account of the remarkable case of malignant disease of the throat, which he is now treating by the application of radium. Experimental observations of the effect of the emanations in various morbid conditions other than malignant disease are being carried out in several widely distant centres. A most suggestive and interesting paper was read by Dr. Darier, on February 17th, before the Académie de Médecine, at Paris, on the use of radium of low radio-active potentiality. The high radio-activity of the pure element is needed for the destructive metamorphosis of new growths, but radio-activity of far lower potentiality can be used in other conditions, apparently with benefit.

The lower grade activities have two advantages; first, they can be used over far longer periods of time—Dr. Darier has used them for as long as six hours at a stretch—and, secondly, the preparations of radium from which the rays are obtained cost only a fraction of the element itself. One of the cases treated suffered from facial paralysis of what seemed to be rheumatic origin, and he was cured by a single application. Two cases of convulsive seizures of a hystero-epileptic character lost their symptoms after three days' exposure to radium emanations directed on to the temples, and another patient of the neurasthenic type was restored to health in a similar period. Remembering the extraordinary degree to which treatment by suggestion was carried in some of the French cliniques a few years ago, one hesitates to take, unconfirmed, these reports as establishing more than a presumption. But in cases where all methods fail in dealing with anomalous functional nervous symptoms—and one is at one's wit's end to devise new ones—the mental and moral effect of radium emanations may procure a result that could not be compassed by other means. If only temporary amelioration can be promised by the use of radium and radio-active substances, they may still be of service to prevent these cases drifting—where they generally do drift—into the hands of the quacks.

Professional Secrecy.

THE usual misunderstandings and the usual crop of comments have been excited by the strictly justifiable attitude taken up by Dr. Parsons, of the Fulham Infirmary, in a recent case of suspected crime. The police had reason to believe that a servant-girl, who had been in the Infirmary, had concealed the birth of a child, whose body was found in a dust-destructor. They made inquiries of Dr. Parsons, who pointed out to them that it was no part of his duties to give them information with regard to the patients under his care. An inquest was held on the child's body, and Dr. Parsons being called, he proceeded to give his evidence on oath. The servant girl was subsequently charged at the West London Police Court with concealment of birth, but in the result was dismissed. The authorities complained to the magistrates of their inability to extract information from Dr. Parsons, when called on by the police, and the magistrate expressed surprise that the doctor should not have done what he could to "assist the course of justice." This incident has given rise to similar expressions of surprise in our lay contemporaries. The burden of professional secrecy laid on medical men will probably never be understood by the public. They are exceedingly indignant when a doctor reveals anything to their hurt, and quite ready to sue him for damages. But in the case of a poor unfortunate servant girl, who has "got into trouble," how the same ethical principle can apply when the girl is not likely to be able to take the offensive they seem unable to grasp. In an English court of law a medical man is bound to reveal secrets confided to him. In France he is forbidden to do even this. A doctor there was fined lately because, in defending an action for negligence brought against himself, he detailed the nature of the case and his treatment. But in this country outside a court of law a doctor is bound by the Hippocratic tradition, and whether the patient be "duke's son, cook's son, or son of a belted earl," his duty is the same. It takes considerable moral courage, especially in those holding public appointments, to act up to the level of their convictions in this matter, and Dr. Parsons is to be congratulated in maintaining his position before the authorities in question with so much firmness and dignity.

Osborne College.

THE King, like all good F.R.C.P.'s, does not "want the natural touch." There is no monarch of ancient or modern times, not even excepting the late Queen, who has shown so admirably what true philanthropy is. Matthew Arnold called religion, "morality tinged with emotion"; we might define philanthropy as "pity tinged with discrimination." The King does nothing rashly—even his good works—and nothing half-heartedly. His gift of Osborne House to the nation for the double purpose of a naval college and a convalescent home for sick officers could not have been more happily conceived. Instead of keeping the beautiful house as a kind of mausoleum, as would have been quite comprehensible under the circumstances, he has perpetuated his mother's memory far more nobly by making it a place where national need and national pity find joint expression. The part of the house that is to be used as a convalescent home is nearly ready for occupation, and the Office of Works have done their work well and efficiently, without much alteration to the existing structure. Provision has been made for thirty-eight single and five married officers' quarters, the former being provided with an elegant bed-sitting room, the latter with two communicating chambers, with the necessary wardrobe accommodation. Sisters' and nurses' quarters are also being prepared, and, of course, rooms for the servants and attendants. The beautiful grounds and terraces overlooking the Solent are to be reserved for the patients' use, whilst the chapel has been turned into a reading and recreation room. Nor has His Majesty's regard for his officers led him to forget one who has served him in another capacity. Miss Haines, the lady who nursed him so devotedly in his last illness, is to be the matron of the home, a reward for her skill and fidelity that does credit alike to herself and her Royal master.

Inquiry into London Tuberculosis.

THE Council of the Royal Institute of Public Health have been moved to consider whether the time has not arrived when a full inquiry into the prevalence and causes of tuberculosis in London should not be made. The eventual object of such

inquiry would be to ascertain what would be the best plan for systematic effort to work on in carrying out repressive and preventive measures. With this idea they have had written a letter to the President of the Local Government Board asking if the Board propose to take any steps with a view to advising on the subject. From the letter it appears that the Metropolitan Asylums Board have already been asked to undertake such an inquiry, and the Council of the Royal Institute still hope that the Board may consent to do so if pressure be exerted by the Local Government Board. Failing this, however, the Royal Institute proposes to set about the task itself. It would be an excellent and public-spirited action on the part of the Institute to undertake a work of such magnitude and importance, and it is to be hoped that if it does so, it will secure the services of men of distinction and authority to sit on the committee. It will be no light matter to investigate and take evidence upon every point that should be dealt with in so enormous a field as that of London tuberculosis, and it is to be feared that the thanks which an unauthorised committee will get will not be at all commensurate with the amount of work its members will have to put in. It is a matter for wonder that the Council of the Institute do not see the absurdity of suggesting that a technical and complicated inquiry of this kind should be undertaken by the Metropolitan Asylums Board. The Board consists of representatives of the Guardians, with a leavening of nominees of the Local Government Board, and counts only two or three medical men among its members. Such a function would be quite foreign to them, and a body less well qualified, both by its experience and its *personnel*, to pursue such an inquiry it would be difficult to conceive.

Resuscitation from Asphyxia.

Apart from the efficacy of mechanical movements imitative of natural respiration, the most important question in the treatment of asphyxia, especially from the lay standpoint, is that of the administration of stimulants. In cases of immersion, artificial respiration is more effective than any stimulant because it acts directly in removing foreign material from the air cells and also in relieving the engorged right side of the heart. When the respiratory movements have once again become automatically established, stimulants may then be given if necessary. In asphyxia from other causes, such as the inhalation of carbonic acid gas or other noxious fumes, it is not so much a matter of removing foreign matter from the lungs as of supplying the needed oxygen to the blood. For individuals who have been "overcome" by the effects of smoke from a fire, it is obviously essential to provide fresh air at once, and that in a concentrated form. We are informed that in Berlin every fire-station has been furnished with an oxygen apparatus for this purpose, and it has been suggested that the London Fire Brigade should follow suit. The ubiquitous brandy-flask is usually forthcoming upon such emergencies in this country, and very often no attempt is made to provide a sufficiency of fresh air for the patient. It is a little difficult to compare the actions of oxygen gas and brandy under these circumstances, for the additional injurious effects of excessive heat have also to be taken into consideration. There can be no doubt, however, that oxygen is a powerful stimulant to the heart as well as to the respiratory centre, and, moreover, its action is sustained and unaccompanied by any depressing after effects. Its expense would be the chief drawback to its general use, and it would also be necessary to have it supplied in small portable cylinders which could be easily conveyed by hand. Should these difficulties be surmounted, oxygen would doubtless prove a valuable addition to the equipment of ambulance and fire-stations.

The Viceregal Slight to the Medical Profession.

The slight which has been put upon the medical profession in Ireland by, as it is generally considered, certain officials at Dublin Castle has been universally condemned in Dublin, not alone by the medical profession but by the general public. The opinion is freely expressed, and we fancy it is correct, that the slight is none of His Excellency's doing, but that it is the result of a notion that has grown in the minds of the Castle officials that the Court of Dublin Castle can be approximated in all particulars to the Court of St. James. We learn that a meeting was held at the Royal College of Surgeons during the past week to consider the reply received from His Excellency's private secretary, and that it was resolved by that body to take common action with the Royal College of Physicians in the matter. We doubt that a change in His Excellency's plans can be effected by such action, or that the Colleges will gain anything by pressing their claim beyond a certain point. Already the matter has been taken up by the Press, and the actions of the Castle officials condemned. If the right of private *entrée* is not restored to the colleges, they will, we consider, best consult and maintain their dignity if their future Presidents refrain from attending the Lord Lieutenant's levées until such time as their position as the titular heads of the medical profession in Ireland is again recognised by Dublin Castle.

Family Predisposition to Disease.

The belief that certain diseases occur in those who are related by family ties, even apart from the influence of heredity, has long been held, both by the general public and also by the medical profession. There can be little doubt about the transmission of a tendency to phthisis or acute rheumatism from one generation to another, and it is usually considered to be a question of an inherited peculiarity of soil whereby the individual is more liable to a specific infection from without than others in whom this special predisposition is wanting. Lithiasis, with its associated condition of arterio-sclerosis, is well known to run in families.

What the exact factors may be which determine the appearances of disease in those of one flesh and blood, it is difficult to ascertain with precision. Any information, therefore, which tends to throw new light upon morbid processes is to be welcomed. The occurrence of uterine fibro-myomata in five members of one family, in all of whom hysterectomy was successfully performed, related by Dr. J. Macpherson Lawrie, (*a*) of Weymouth, is of great interest in connection with this subject. Another curious pathological feature is that all five sisters were also affected with cataract. Several instances have been recorded, from time to time, where fibroid disease of the uterus has been met with in more than one member of the same family, and in some of these the affection has been traced back for one or two generations. The suggestion that the degenerative changes affecting two important tissues of the body, the uterine and the lenticular, may be due to one common factor indicating some inherited weakness of the organs concerned sounds tempting enough, but our knowledge of the conditions affecting the development of the germ-cell is so small that it would probably be more scientific to regard these associations as merely accidental.

Irish Maternity Hospitals and the Central Midwives Board.

WE publish a letter from Dr. Ward Cousins in another column regarding the attitude of the Central Midwives Board towards the great Irish maternity hospitals, as well as his Report to the English College of Surgeons. It will be remembered that we published in our last issue a copy of the correspondence which has passed between the Master of the Rotunda Hospital and the Board. In a covering letter from the Secretary of the Board to the Master of the Rotunda, the statement was made that the resolution "regretting" that the Board were unable to recognise Rotunda trained nurses had been unanimously adopted by the Board. This, it appears, is an incorrect statement, inasmuch as Dr. Cousins was present at the meeting and did not support the resolution. It also appears that Dr. Japp Sinclair was absent from the meeting, and as he is capable of forming an opinion of the merits of the different methods of training nurses, we think we may assume that if he had been present he would not have supported the resolution. It will doubtless interest the heads of the Irish maternity hospitals to learn that Dr. Cousins considers the treatment to which they have been subjected of sufficient importance to present a statement of it to the Royal College of Surgeons of England. The Irish maternity hospitals have every reason to be grateful to Dr. Cousins for his support.

Death of two German Pioneers in Tuberculosis.

WITHIN the last few days two figures prominent in the treatment of tuberculosis have disappeared from the world. Clur was the exponent of the climatic treatment, and preached mid-ocean island climates; while Detweiler was among the first of our modern pioneers for the open-air treatment on high situations. As a young man he went as assistant to Brehmer, who had a sanatorium, a rare thing in those days, in Gerbersdorf, where he wrote much on the Brehmer treatment and elevated situations. Later in life Detweiler went to Falkinstein, in the Taunus Mountains, where we find his opinions are more in favour of exposure rather than elevation. On this subject a severe battle was fought between him and Brehmer, and minor skirmishes often took place till Brehmer died. Toxins and antitoxins were equally discussed, while tuberculins, tuberculozidins, the serum of Maragliano, Marmoreck, &c., have all been tested in turn. There is one of the phthiseo-therapies of Detweiler that is remembered against him as a blemish in the treatment of tuberculosis, *viz.*, the liberal use of alcohol. His advice was alcohol at every meal, and never go out without it.

(*a*) *Brit. Med. Journ.*, February 23rd, 1904.

The Birth of Giants.

A WRITER in one of our Continental contemporaries has made an interesting collation of the records of the births of giant children in the Königlichen Charité at Berlin. The term "giant," it may be necessary to explain, is applied to infants who weigh over 4,000 grammes. In this sense it appears that the average of giant births to the total number of births, for a period of ten years, was about 3½ per cent. In most cases the mothers were women of over thirty years of age, multiparæ, with large pelves. As might be expected, the time of expulsion of giant children averages much longer than that in normal birth. In most cases there was no actual difficulty, and when artificial delivery was necessary, it was usually merely on account of the size of the child. In fact, although the term "contracted pelvis" cannot correctly be applied, yet, in view of the increased size of fœtus, this term best expresses the kind of difficulty met with. Abnormal presentations were rare, and prolapse of the cord less frequent than usual. Lacerations of the soft parts were, as might be expected, common. Curiously enough, the mortality-rate among the mothers was lower than normal, but on the other hand the rate among the children was four times as high among giants as among others. A surprising result appears when the relative number of boys and girls are noted, for there are nearly three times as many male giants as female. At the same time the average weight among the females was as great as that among males.

The Carnegie Trust and Scotch Students.

THE lines of students in Scotch medical schools and universities seem to have fallen in pleasant places so far as fees are concerned. We learn that under the Carnegie Trust the total number of beneficiaries since the institution of the Trust until December 31st, 1903, was 4,517. There has been paid by the Trust for summer session, 1903, the sum of £13,569 12s. on behalf of 1,755 students, repre-

senting the fees of 5,392 class attendances; and for winter session 1903-4 the sum of £30,510 15s. on behalf of 3,027 students, representing the fees of 8,976 class attendances—in all, for the year to December 31st, 1903, the sum of £44,080 7s. Of this golden shower we presume the medical students partake. It is to be hoped, however, they do not figure in the latter part of the following announcement:—"During the year 1903 six students have voluntarily refunded the fees paid for them by the Trust to the amount of £72 2s. There is also a decrease in the number of cases where return of fees has been demanded from beneficiaries who have failed to obtain requisite certificates of attendance and work." The committee have entered into an agreement with the Royal College of Physicians of Edinburgh by which the Trust has purchased the property and laboratory of the college in Forrest Road, Edinburgh, for £10,000. During the past year the claims of extra-mural schools have received attention. After inquiry and conference two cases have been dealt with—that of the medical school of the Royal Colleges of Edinburgh, and that of the Medical College for Women, Edinburgh; and under certain conditions limited grants have been offered for permanent equipment and provisional assistance.

A New Use for the X-Rays.

The phenomena of radio-activity are so surprising in their effects upon organic and inorganic substances that fresh spheres of usefulness seem to be discovered for them almost daily. The power of the X-rays to influence cell growth is taken advantage of in the treatment of malignant disease, while their physical property of penetrating objects hitherto deemed impenetrable renders them indispensable to surgical work. Now we are informed that they are accredited with certain psychic effects, for M. A. Béclère has reported a case of hysterical mutism cured through their agency. The patient was a young married woman, aged 26, who received a severe mental shock through witnessing a conflagration. She suddenly lost consciousness, and on recovering herself found she had completely lost the power of speech. She was consequently admitted into the Hôpital Saint-Antoine. The pharyngeal and corneal reflexes were abolished, and there were irregularly scattered areas of anæsthesia and hyperæsthesia about the body. There was no paralysis. Methylene blue was prescribed, together with active suggestion, but this treatment proved of no avail, for four days afterwards she was still aphasic. She was then taken to a room where other patients were about to undergo radioscopic examination. The apparatus and the dark surroundings caused her some alarm, but when the current was switched on she recovered her speech from that moment. The influence of suggestion was, no doubt, not unimportant in the production of the beneficial result, but the rays were the medium through which it acted. Any sudden or unexpected shock, such as the application of the galvanic current to the glottis, will generally effect a speedy cure in cases of hysterical aphonia, but where other methods have failed the psychic influence of the X-rays might well be borne in mind.

Small-pox in the Provinces.

As anticipated, the London epidemic of small-pox reappeared in a mild form in 1903, and still lingers on in 1904. The field open for its invasion has been narrowed down to an extremely small margin by the number of "unprotected" persons who were attacked by the disease in the earlier days of the outbreak, and also by the wholesale protection of previously "unprotected" citizens by vaccination and re-vaccination. It was almost inevitable in these times of rapid and universal commerce and transit that the huge mass of small-pox infection centred in the Metropolis should give rise to scattered epidemics throughout the Kingdom. That, indeed, has happened. In some instances the disease has been conveyed by tramps. Glasgow, Liverpool, Derby, Sheffield, Cardiff, and many other towns in England, Scotland, Ireland, and Wales, have been invaded more or less disastrously with small-pox during the past two years. Nottingham and Derby appear to be on the eve of a serious epidemic. It is to be hoped that the moral of these events will not be lost upon those of our weaker brethren who have not made up their minds as to the efficacy of vaccination. In London the advent of the small-pox brought shoals of unbelievers and scoffers to their senses. An anti-vaccinator who gets vaccinated when small-pox comes into his parish is in much the position of Mrs. Eddy, who went to the dentist and had a tooth extracted instead of applying her creed that pain has no existence in fact, and that faith and prayer are all-sufficing substitutes for the art of the medical man and the dental surgeon.

Anæsthesia with Sterile Water.

Hydropathic enthusiasts, and for that matter, all practitioners who believe in the occasional therapeutic propertics of water, will be interested to learn that the use of water as a local anæsthetic agent is being revived. The idea is by no means new, having been formulated by Burney Yeo and Griffith in 1868. Dr. Samuel G. Gant, of New York, has recently called attention to this little-known property of water when injected under the skin. The theory of its action is that the tissues are so distended that the sensory nerve-endings in the epidermis are compressed in such a manner as to temporarily paralyse their function. In the case of a superficial abscess, in which the same thing might be supposed to occur, this compression is gradual owing to the slow accumulation of inflammatory products and subsequent suppuration, resulting in acutely painful sensations. But when a fluid is injected from without, the distension is sudden and unexpected, so that the contrary effect, anæsthesia, is produced. Dr. Gant has employed the method more particularly in surgical affections of the rectum and anus, such as fissures, hæmorrhoids, and polypi. It is claimed

that the use of a general anæsthetic may be dispensed with, that the anæsthesia is quickly obtained and that systemic complications are avoided. The after pain is said to be less than when cocaine or eucaine has been used, and the risk of a possible toxic action of these substances is, of course, removed. The more the tissues are distended, the greater the anæsthesia. Simplicity of apparatus is certainly one point in its favour, all that is needed being a syringe full of sterilised water, but in nervous and sensitive patients it is questionable whether even the puncture of a needle in the delicate hæmorrhoidal area would be tolerated. Where it is known that a morbid susceptibility to cocaine is present and a general anæsthetic inadvisable, this method might then be worthy of a trial.

Longevity in Ireland.

BY no means the least interesting part of the "Quarterly Return of Marriages, Births, and Deaths," issued by the Registrar-General for Ireland, is the section devoted to remarks made by the local registrars on matters concerning the public health of their districts. On looking over the return for the last quarter of 1903 recently issued, one cannot but be struck with the great number of cases recorded of deaths occurring at advanced ages. In the Cavan district a death has been registered at the age of 120 years, and at Ballycroy, in co. Mayo, one at the age of 113, which age the registrar believes to be accurate. In addition to these, no less than thirteen other centenarians are reported to have died during the past quarter. Curiously, of those who just failed to reach the even hundred, the number is somewhat less, as only nine deaths are drawn attention to as occurring between 90 and 100. When we come to octogenarians the numbers rapidly increase, as notes are made of about thirty deaths between 80 and 90, and there are probably many more of which the registrars do not think it worth while to make special mention. A comparison of the mortality among old people with that among the total population also gives some interesting facts. For example, out of thirty deaths in the Grean district, co. Limerick, thirteen occurred at ages exceeding 73 years. In the Ederney district of Fermanagh, the total number of deaths was thirteen, of which nine were at ages varying from 70 to 97. Out of twenty deaths in the Kilsea district of Londonderry, eight were at ages over 75. These instances are all taken from rural areas, where life may reasonably be expected to be long; but looking at the whole of Ireland, town and country, it would appear that about half the total number of deaths occur after the age of 60. It would add interest to future issues of the already very interesting quarterly returns if a column were added including all deaths registered at ages above 80 years.

PERSONAL.

Mr. A. W. MAYO ROBSON has been chosen Bradshaw Lecturer by the Royal College of Surgeons of England for the ensuing collegiate year.

IT is reported that the well-known American surgeon, Dr. William Senn, will act as Surgeon-General of the Japanese Army.

DR. ROBERT J. ROWLETTE has been appointed Lecturer in Pathology to the Queen's College, Galway, for the year 1904.

WE understand that Sir Christopher Nixon, ex-President of the Royal College of Physicians of Ireland, may become a candidate for Parliamentary honours in the St. Stephen's Green Division of Dublin.

A LECTURE on "Trypanosomes and Sleeping Sickness at Uganda" was delivered in the zoology theatre of the Liverpool University on February 12th by Colonel David Bruce, F.R.S., R.A.M.C., under the auspices of the Liverpool Biological Society.

THE gold medal established by the friends and pupils of Mr. Nettleship, to commemorate his work in ophthalmic surgery, was recently handed over to the custody of the Ophthalmological Society of the United Kingdom by Sir Thomas Barlow, representing the subscribers to the fund.

THE annual dinner of the medical officers of the auxiliary forces will take place at the Imperial Restaurant, Regent Street, London, on Friday, April 15th, at 7.30 p.m., under the presidency of Lieutenant-General Lord Grenfell, G.C.B., G.C.M.G. Tickets may be had from Lieutenant Montgomery-Smith, 36 Abbey Road, N.W.

THE members of the Ulster Medical Society have arranged to have a marble bust of Sir William Whitla done for the entrance hall of the Medical Institute, the building which he presented to the Society a a little over a year ago. The execution of the work has been entrusted to Miss Kathleen Shaw (daughter of the late Dr. Shaw), who has lately completed an excellent bust of the Irish Primate, and is now engaged on one of His Eminence Cardinal Logue.

DR. JAMESON of "the Raid" notoriety, has been entrusted with the formation of the new Cabinet of the Cape Ministry. It may be added that Dr. Jameson was compelled to relinquish medical practice in London nearly a quarter of a century ago on account of his health; he settled in Kimberley, became medical adviser to the late Mr. Cecil Rhodes, took part in the Matabele war, and became administrator of Rhodesia in 1891. He now becomes Premier of Cape Colony.

Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

EDINBURGH.

THE LATE DR. ROBERT MILNE MURRAY.—The announcement of the death of Dr. Milne Murray will come as a great blow to the many who were privileged with his personal acquaintance, and will be deplored by the wider circle of workers in all departments of scientific medicine, particularly in the field of obstetrics and gynæcology, where he made for himself a world-wide reputation. About fifteen months ago, while engaged in professional work, he contracted pneumonia, and since then had been more or less completely laid aside; while for a considerable time hope of his recovery was entertained, the disease latterly progressed, and he died on February 14th. Dr. Milne Murray was born in Kincardineshire in 1855. The son of a gifted father, a schoolmaster, he passed from his tuition to St. Andrews, where he took an Arts degree

at the age of 20, whence he came to Edinburgh to study medicine and graduated in 1875. Thereafter he became associated with Sir Halliday Croom as his assistant, and this determined for him the selection of obstetrics and gynæcology as his life work. He very rapidly acquired eminence in his specialty, and filled in turn the position of President of the Edinburgh Obstetrical Society and vice-president of the British Gynæcological Society, while at the time of his death he was one of the physicians to the Maternity Hospital and assistant gynæcologist at the Royal Infirmary. About ten years ago, he, along with four or five colleagues, took an active part in establishing the New School, which is one of the most important teaching centres in the School of Medicine of the Royal Colleges, and in the lecture rooms of which he conducted one of the most popular and successful classes in midwifery in Edinburgh. He was eminently clear and practical as a teacher, while his numerous contributions to medical literature were concise, original, and authoritative. Milne Murray's great strength as an obstetrician and gynæcologist lay in the fact that his interests were by no means bounded by the limits of his own specialty, but that he brought to bear on its problems a mind versed in other departments of science. He was esteemed an expert in other departments besides his own specialty, and particularly in electrical science, which was for him something more than a hobby. His collection of electrical apparatus, gathered together at great cost, is unique, and his private laboratory was much visited by distinguished electricians. His services as an expert in this branch of science were greatly in request, and he it was who was consulted by the managers of the Infirmary in connection with their electrical installation, which was further directed by him as official electrician to the institution until the date of his appointment as gynæcologist. In addition to these scientific attainments he had considerable artistic talents, and was a musician of no mean order. Of his personal qualities this is hardly the place to speak. Through his death many have lost a dear friend, and more a wise and genial counsellor. He is survived by a widow but no family.

Carnegie Trust.—Third Annual Report.—The third annual report of the Executive Committee was published on February 20th. Of the grant of £40,000 allocated to the universities for permanent equipment and teaching endowment, over £20,000 has been claimed and paid over. This sum includes the grants of £1,000 to each of the libraries, and £2,400 for provisional assistance, which have been claimed in full, £7,725 claimed for buildings, and £6,200 for endowment of teaching. The funds of the trustees have been partially or wholly instrumental in founding a chair of history in Aberdeen, a chair of geology in Glasgow, lectureships in French and botany in St. Andrews, and grants in aid of modern languages in Edinburgh and of German in St. Andrews have also been made. Under the scheme for the endowment of post-graduate research awards have been made, as published last July; 156 applications were received, and five fellowships and fifteen scholarships created, while grants were made to fifty applicants. As to grants in aid of research, the general principle adopted was that these should not include payments for personal expenses or assistance in work. In pursuance of their policy of retaining the administration of the endowment of research, in their own hands the Committee have purchased the laboratory of the Royal College of Physicians, on the understanding that the annual contributions of that College and of the College of Surgeons be continued, and that the Trust have two representatives on the Board of Management. This arrangement is to remain in force for five years, at the end of which time, should either party desire to terminate it, the College may repurchase the laboratory. The amount paid for class fees during the year 1903 was £44,000, and while the Committee do not anticipate that during the current year the claims will exceed the available income, they have prudently made the requirements as to preliminary education somewhat more stringent, and have barred payment of fees for non-obligatory classes unless in special cases.

GLASGOW.

Southern Medical Society, Glasgow.—At the beginning of the session Sir J. Halliday Croom, Edinburgh was unanimously elected honorary President of the Society. Probably over a hundred members of the profession, including many of the consultants, met in the Faculty Hall, 242 St. Vincent Street, on the evening of Thursday, 18th inst., to hear Sir Halliday deliver his address on "Some Moot Points in Cancer." Mr. Thomas Richmond, President, occupied the chair. As was to be expected, the address was as eloquent as it was exhaustive and instructive. We expect to give a fairly full report of this contribution to the literature of cancer, which is exciting considerable attention at the present time. On the motion of Professor McCall Anderson, seconded by Professor Murdoch Cameron, a very hearty vote of thanks was awarded Sir J. Halliday Croom for his extremely interesting address.

The Sanitary Institute of Great Britain.—The meetings of the above are to be held this year in Glasgow during the month of July. Preliminary meetings have been held, and various influential committees formed. The Corporation of Glasgow has very generously agreed to meet the entire expense, and it is expected there will be a considerable amount of private entertaining. It is certainly unfortunate that the date fixed—the end of July—corresponds with the annual meeting of the British Medical Association at Oxford, which will certainly attract large numbers. Many medical men are on the committees formed for the Sanitary Congress. It was explained that the matter had been very carefully considered, but the date could not be altered. All that remains to be said is that it is rather unfortunate.

Small-pox in Glasgow.—This disease is still prevailing in the city to an extent that is causing the authorities considerable uneasiness. There are at present in Belvidere Hospital 172 cases. A circular was recently issued by the Medical Officer of Health, Dr. Chalmers, to the members of the profession, inviting them to vaccinate all who may apply, the Corporation defraying the expense to the extent of giving a fee of 1s. 6d., the operator to find his own lymph! Few medical men have taken advantage of this parsimonious offer, and rightly so. The result is that small-pox is allowed to go on spreading from day to day. A large economic question is involved which the Corporation will in all probability have to face when public opinion is aroused, and that at an early date.

Correspondence.

THE CENTRAL MIDWIVES BOARD.

To the Editor of The Medical Press and Circular.

Dear Sir,—You say in your article to-day on "The Central Midwives Board and the Irish Maternity Hospitals," that the Board resolution was *unanimously* adopted, and I write to inform you that this is incorrect. Seven members of the Board were present at the meeting. I did not support the resolution, and Miss Oldham and Dr. Sinclair were absent.

I am, Sir, yours truly,

Ward Cousins.

Southsea, February 17th, 1904.

[We are much obliged to Dr. Ward Cousins for his correction, especially as it discloses a very improper and misleading mistake on the part of the Secretary of the Central Midwives Board, who, in writing to the Master of the Rotunda Hospital, used the following words:—"I am directed to point out that the Rules were approved by the Privy Council on August 12th, 1903, and to forward you a copy of the resolution, which, having regard to that fact, the Board passed *unanimously*." The italics are ours.—Ed. Medical Press and Circular.]

Literature.

CONSUMPTION. (a)

THIS work, as Professor Koch indicates in his brief introduction, is intended as a popular exposition of the tuberculosis question. It is primarily addressed to English readers. The author claims that his book "deals with tuberculosis as a great social problem which is at present exercising the minds of medical men, legislators, local and public health authorities, and intelligent citizens in every civilised country in the world." Dr. Hillier has no hesitation about his text: "Tuberculosis may be cured, can be avoided, and ought to be prevented," and he insists on the infectious character of phthisis to an extent which we venture to think is likely, at least in certain quarters, to develop a dangerous and very undesirable phthisiophobia. The work opens with what purposes to be a description of the history and nature of tuberculosis, but it is peculiarly incomplete. We are told that Botticelli's Venus died of consumption at an early age, and more than a page and a half are devoted to the writings of antiquity, while extensive reference is made to the views of physicians in the Middle Ages, but we have searched the index in vain for any note of such pioneers as Parrish, Bodington, MacCormac, and B. W. Richardson; even the names of Brehmer, Detweiler and Walthers are conspicuous by their absence. Dr. Hillier teaches that there is much danger from cough-sprayed sputum. We are inclined to believe that he lays far too much stress on this mode of infection. It is amusing, as well as pathetic, to find Fränkel's respirator figured and carefully described. Dr. Hillier's method, if allowed free course, would, we fear, go far to make every consumptive a social outcast.

The relation of bovine to human tuberculosis is discussed fairly fully, and, as might be expected, Koch's views have great prominence.

There is a useful section on personal precautions which, so far as it goes, is good. The chapter on public action raises many points still under discussion, but there is a lack of statesmanlike grasp of the subject. Dr. Hillier is an ardent advocate of compulsory notification. The section dealing with sanatoria is far too scrappy to be of much service. The author describes the institution with which he is connected, but he might well have drawn attention to some of the excellent features to be found in the many other sanatoria which are now to be found in almost all parts of the country. In discussing the financial aspects of the question, reference is made to German methods, but few suggestions are presented regarding measures likely to find favour with English people.

The work is disappointing. It is full of evidences of haste and hurry. Its incompleteness, and, as it appears to us, its unscientific dogmatism, will much militate against its usefulness. The author lacks the judicial spirit, and his clinical work is not sufficiently based on a perception of the limitations of our pathological knowledge.

Undoubtedly, the most useful portion of the book is to be found in the appendix, which contains matter reprinted from the publications of the National Association for the Prevention of Consumption; a description by Dr. W. B. Ransom of the Nottinghamshire sanatorium; particulars of sleeping accommodation as provided at the interesting Kelling Sanatorium in Norfolk; a note on homes for advanced consumptives; and an essay on State insurance for workmen in Germany.

ZOOLOGICAL STUDIES IN MALAY. (b)

THIS work describes the result of an expedition undertaken by Messrs. N. Annandale and H. C. Robinson to study the zoology of the Malayan mainland, and will doubtless prove of value in the hands of all interested in the fauna of that region. The report on the amphibia and reptilia is especially interesting, six new forms being described. The collection of mammals, of which sixty-four were obtained, including eight new species, is a notable contribution to our knowledge of the zoology of this district. The notes on the mammalia also contain several interesting facts relating to the habits and distribution of certain new species. The other descriptions of the Heterocera, Cicendelidæ, and Odonata, also deserve the attention of the student of these groups. Notwithstanding that the writers were unable, for various reasons, to pay particular attention to the collection of molluscs, five new species were obtained. The Rhynchota were remarkable by the absence of many common forms, and by the presence of a large number of obscure and little-known, or new species, and even some new genera. The reports contain papers on marine fishes, a list of fresh water fishes, and other studies which will be of value to investigators in this department of biology. Messrs. Annandale and Robinson publish in the form of a supplement an itinerary of their travels, giving a general account of their wanderings in the little-known Malay States under Siamese rule. The account is mainly of a personal nature, with a brief description of the various districts and villages in which they sojourned, and a note on the work done in each place. It forms a convenient epitome of the investigations of these most industrious explorers. The report is admirably illustrated, and all concerned in the appearance of these excellent studies may well be congratulated.

Obituary.

MR. DAVID KENNARD, M.R.C.S., L.S.A.

As the result of an accident in the hunting field, a well-known county practitioner, Mr. David Kennard, met with his death. He was a student at Westminster Hospital, and took the M.R.C.S., Eng., in 1860. For many years he has been a prominent social and professional figure in Berkshire society. His chief appointment was the medical officership of the Lambourn District Hungerford Union.

DEPUTY-SURGEON-GENERAL JAMES LEITCH.

WE regret to note the death of Deputy-Surgeon-General James Leitch, of the Army Medical Department, a native of Crieff, and son of the late Dr. James Leitch, R.N., on the 12th instant, at his residence, Claremont Street, Edinburgh. He had attained the age of 79 years. On passing through the various grades of his profession in the army Dr. Leitch accompanied the 78th Highlanders to India, and was on active service there during the Mutiny in 1857.

GEORGE NIVEN, M.A., M.B. Cantab.

ON February 7th, Dr. George Niven succumbed to pneumonia. Dr. Niven was born at Peterhead, and had a distinguished career as a student at Aberdeen, where he took his M.A. degree in 1877, and at Cambridge, where he took the B.A. in 1882, and M.B. in 1886, obtaining also in the latter year the diploma of M.R.C.S. On the completion of his university studies, he entered upon professional practice at Didsbury, Manchester. He leaves a widow and three young children by his early death at the age of 45.

MR. EDMUND SAMUEL WARBURTON, M.R.C.S.Eng., L.S.A.

THE medical practitioners of the Rhondda valley, have lost a valued colleague and the colliers a trusted friend and a skilled surgeon through the death on February 6th of Mr. E. S. Warburton, of Treherbert. He was born nearly sixty years ago in Cheshire and came of a family of medical men. After making several

voyages as a ship's surgeon he settled in Treherbert in 1874, when the Rhondda valley was beginning to be developed, and was appointed surgeon to several large collieries. He was a very able diagnostician and a most capable operator. Although educated in an older school, he was always abreast of the times, and ready to give his patients the advantages of the newest remedies; for example, when diphtheria was epidemic in the district a few years ago, he was one of the first to recognise the value of the antitoxin treatment.

INSPECTOR-GENERAL OF HOSPITALS AND FLEETS WILLIAM MACLEOD, C.B., R.N.

WE regret to announce the death of Inspector-General of Hospitals and Fleets William MacLeod, C.B., R.N., at his residence, West Kensington, at the age of 84. Educated at Edinburgh University, where he took the degree of M.D. in 1841, he entered the Navy as an assistant-surgeon in 1842, and served on the China station in that rank from 1845-47. He was surgeon of the "Driver" in the Baltic during the Crimean War, and of the "Madagascar" in 1859 at Rio de Janeiro during a severe epidemic of yellow fever, and for his journal and report of that year received Sir Gilbert Blane's Medal. Promoted to the rank of Deputy-Inspector-General in 1866, he was in charge of the Royal Naval Hospital at Yarmouth from that year until April, 1875, when he was promoted to the rank of Inspector-General. He continued in charge at Yarmouth until 1880, when he retired from the Navy. In November, 1880, his services were recognised by the award of the Companionship of the Bath, and eight years later he received a Greenwich Hospital Pension.

Medical News.

Re British Medical Association's Proposed Scheme for Medical Defence Department.

AT a meeting of the Council of the Medical Defence Union held at the registered offices February 18th, the following resolution was unanimously passed:—"That this Council resolves to do all in its power to maintain the integrity of the Medical Defence Union as at present existing."

The Ballachulish Quarry Dispute.

AT a special meeting of the Ballachulish Workmen's Medical Society held last week it was unanimously agreed that the expenses of the legal actions incurred by the Medical Club and Dr. Grant during the recent dispute should be paid by the Society. This is a most satisfactory ending to this prolonged controversy, which has, in no small degree, vindicated the honour and standing of the medical profession.

The London School of Tropical Medicine.—Craggs' Research Prize.

A PRIZE of £50 will be awarded to a past or present student of this school who during the current year (October to October) makes the most valuable contribution to Tropical medicine. Contributions must be written in English, and essays must be sent in on or before October 1st next, to the medical tutor at the London School of Tropical Medicine, Royal Albert Dock, E., who will gladly afford further information.

The Bristol Eye Hospital.

THE annual meeting of the subscribers to the Bristol Eye Hospital was recently held, under the presidency of the Lord Mayor. The annual report stated that during 1903 the in-patients numbered 486, being 21 in excess of those for 1902. The out-patients were 6,869, being an increase of 915 compared with the previous year. The financial statement showed that the subscriptions received amounted to £660, and that a deficit of £593 remained.

The Nurses Registration Bill

THE Nurses Registration Bill, promoted by the Society for the State Registration of Nurses, was introduced by Dr. Farquharson, and read a first time in the House of Commons on Monday last. It is backed by Mr. Haldane, Sir Thomas Wrightson, Sir James Joicey, Sir John Tuke, Mr. H. C. Smith, Mr. Munro Ferguson, Mr. Tennant, Mr. Black, Mr. Colston, Mr. Eve, and Dr. Thompson, and the second reading was put down formally for Monday next.

The Medical Officer of the Female Prison, Limerick.

ON Monday last Mr. Joyce asked the Chief Secretary in the House of Commons if he would explain why the services of Dr. John Holmes, medical officer to the Female Prison, Limerick, had been dispensed with; what number of years Dr. Holmes had been in charge of the prison, and what pension or compensation in lieu of pension, if any, had been offered to him. Mr. Wyndham replied that Dr. Holmes had held the position of temporary medical officer of the Limerick Prison for 13 years. His services had been dispensed with upon the amalgamation of the medical officerships of the male and female prisons. He was not entitled to any pension or compensation.

The Associated Hospitals Association.

THE Associated Hospitals Association, which represents the lay and medical staffs of all the London Hospitals with medical schools attached, have decided to oppose the Nurses Bill. Sir F. Dixon-Hartland has placed on the Paper a motion for the rejection of the Bill.

Free Dispensary for Aliens.

SIR SAMUEL MONTAGU and other wealthy members of the Jewish faith are taking steps to establish a free dispensary for East End aliens, so that they shall not be chargeable to the rates for medicine, &c.

Should Medical Men Dispense

AT a meeting of the Central Division of the Metropolitan Counties Branch of the British Medical Association, held at Chandos Street, W., a motion that a clause be added to a draft Medical Acts Amendment Bill proposing that doctors should not, under pain of a heavy penalty, supply drugs or medicaments to anyone, was lost by an overwhelming majority. Exceptions were mentioned, and these covered medical officers on ships and in the army, emergency medicines and certain sparsely-populated areas which could not support both a doctor and a chemist. A few expressed approval of the principle of the motion, but not the means proposed, and only two voted for the resolution

Ambidexterity.

"THE Ambidextral Culture Society for the Promotion of Symmetrical, Physical, and Mental Development" has arranged a course of lectures, to be given in the rooms of the Medical Society of London at 5 p.m. during the next four months. The subjects will vary from ambidexterity in fly-fishing to the same accomplishment in the infants' school. Further particulars can be obtained from the honorary secretary, St. Dunstan's House, Fetter Lane, London, E.C.

The Treatment of the Blind in Ireland.

IN the Commons Mr. Nannetti asked the Chief Secretary to the Lord Lieutenant of Ireland whether it was the intention of the Government to deal with the condition of the blind in Ireland during the present session, in accordance with the finding of the Royal Commission of 1889, which recommended special treatment for them. Mr. Wyndham answered that he could not give a pledge to deal during the present session with the condition of the blind in Ireland in accordance with the recommendations of the Royal Commission of 1889.

PASS LISTS.

Society of Apothecaries of London, February, 1904.

THE following candidates passed in:—*Surgery*, R. H. Cooper (Section I.), and W. G. Kinton (Section II.). *Medicine*, J. Bromley (Sections I. and II.), R. H. Cooper (Section I.), W. G. Kinton (Section II.), N. O. Roberts (Section II.), and S. Zweiback (Section II.). *Forensic Medicine*, M. B. Taylor. *Midwifery*, G. W. Rogers, and A. C. Story. The Diploma of the Society was granted to the following candidate, entitling him to practise medicine, surgery, and midwifery:—W. G. Kinton.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

RUSTICUS (Bucks).—The best thing is to confirm the diagnosis of impacted fracture by a Rontgen-ray photograph of the hip. You will have to get an operator with apparatus from town. In our opinion it is fairer to the profession to get a medical man. It will be wiser to warn your patient that shortening may occur from absorption some time after apparent recovery.

DR. H. W. A. ZEISS.—One-twelfth inch oil immersion lens will serve your purpose.

RONTGEN RAY (Eastbourne).—Write to Mr. Harry Cox, Cursitor Street, London, E.C., for a treatment tube.

BASTOHAN.—(1) We know no book on the subject. (2) The harvest mouse is distinguished from all other British mammals by the fact that it has a prehensile tail.

SCRUTATOR (Croydon).—The League of Mercy, as you say, is doubtless founded on principles that are in the main praiseworthy. We note, however, that the tradesmen and the administration are all paid with one exception, namely, the medical attendant. Why should not the skilled service of the medical man be recognised like all other indispensable services? Some day the hollowness of gratuitous medical work will be recognised everywhere, yet no gratuitous post goes long a-begging.

QUÆRENS.—It seems to be more than probable that the injection of paraffin by an unqualified person as a plastic operation to remedy a defectively shaped nose, if followed by disastrous consequences, would lay the operator open to an action for very heavy damages. The Medical Act is so defective that anyone possessed of moderate cunning and caution can practise medicine or surgery for a livelihood without the slightest dread of consequences.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 24th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Clinical Evening. Exhibition of Cases.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. H. L. Barnard: Clinique. (Surgical.) 5.15 p.m. Mr. S. Stephenson: Some of the Newer Remedies in Eye Disease.

THURSDAY, FEBRUARY 25th.

HARVEIAN SOCIETY OF LONDON (St. Mary's Hospital).—Clinical Meeting. Patients will be in attendance at 8.15 p.m.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret Street, W.).—8 p.m. Lecture.—Mr. H. Hall: On Some Elementary Aims in Education.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique (Surgical.) 5.15 p.m. Mr. E. Clarke: Errors of Refraction, their Diagnosis and Treatment.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy Square, W.).—5 p.m. Dr. T. D. Lister: The Treatment of Advanced Phthisis at Home. (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6.15 p.m. Dr. M. Dockrell: Acne. (Chesterfield Lecture.)

FRIDAY, FEBRUARY 26th.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Clinique.

Vacancies.

Aberdeen City District Lunacy Board.—Assistant Medical Officer, Salary £110 per annum, with board. Applications to C. B. Williams, Clerk, 20, Union Terrace, Aberdeen.

Birmingham and Midland Eye Hospital.—House Surgeon, Salary £75 per annum, with board and attendance. Applications to the Secretary.

Bradford Children's Hospital.—House Surgeon, Salary £100 per annum, with board, residence, and washing. Applications to C. V. Woodcock, Secretary.

Cheltenham General Hospital.—Junior House Surgeon, Salary £70 per annum, with board, lodging, and washing. Applications to H. T. Carrington, Hon. Sec. and Treasurer.

Clayton Hospital and Wakefield General Dispensary.—Junior House Surgeon, salary £80 per annum, with board, lodging, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Denbighshire Infirmary, Denbigh.—House Surgeon, Salary £100, with board, residence and washing. Applications to J. Parry Jones, Secretary.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer Salary £100 per annum. Applications to Thomas Hayes, Secretary.

Gesto Hospital, Isle of Skye.—Resident Medical Officer, Salary £200 per annum, with furnished house, coals, light, and taxes. Applications to the Secretary, J. Simpson, North of Scotland Bank, Limited, Portree, Skye.

Guest Hospital, Dudley.—Senior Resident Medical Officer, Salary £100 per annum, with board, residence, attendance and washing. Applications to the Secretary.

Joint Counties Asylum, Carmarthen.—Junior Assistant Medical Officer, Salary £150 per annum, with board, furnished apartments, and washing. Applications to Dr. Goodall, Medical Superintendent, the Asylum Carmarthen.

Salford Royal Hospital.—Junior House Surgeon, Salary £70 per annum, with board and residence. Applications to George Ruddle, Secretary and Superintendent.

St. Mary's Hospital, Paddington, W.—Resident Casualty House Surgeon, Salary £100 per annum, with board and lodging. Applications to Thomas Ryan, Secretary.

West Bromwich District Hospital.—House Surgeon, Salary £100 per annum, with board, residence and washing. Applications to Thos. Foley Rache, Esq., Churchill House, West Bromwich.

West Riding of Yorkshire.—Bacteriologist and Assistant to County Medical Officer. Salary £250 per annum. Applications to Trevor Edwards, Clerk to the Committee.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer, Salary £140 per annum, with board, &c. Applications to the Medical Superintendent.

West Riding Asylum, Wadsley, near Sheffield.—Fourth Assistant Medical Officer, Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.

Appointments.

ANDREWS, MARION, M.B., Surgeon to the Women's Department, Ulster Hospital for Children and Women, Belfast, vice Dr. John Tennant, resigned.

BENNION, J. M., M.B.Cantab., Junior House Surgeon to the Radcliffe Infirmary, Oxford.

CURL, SYDNEY W., M.A., M.B.Cantab., M.R.C.P.Lond., Pathologist and Bacteriologist to the North-Eastern Hospital for Children, Hackney Road.

EWART, D., M.B., B.S.Edin., F.R.C.S.E., Certifying Surgeon under the Factory Act for the Chichester District of the county of Sussex.

FOSTER, C. W., M.R.C.S., L.R.C.P.Lond., House Surgeon to the Radcliffe Infirmary, Oxford.

GARDNER, A., M.B., C.M.Edin., Medical Officer of Health for the Kirbymoorside District of Ryedale, Yorkshire.

GIBSON, A. G., M.B., B.Ch.Oxon., House Physician to the Radcliffe Infirmary, Oxford.

IVENS, FRANCES, M.S.Lond., Surgical Assistant to the New Hospital for Women.

MANNING, RICHARD BEATTIE, L.R.C.P.Lond., M.R.C.S., Honorary Medical Officer to the Wells (Somerset) District Cottage Hospital.

MARSH, C. J., L.R.C.P.Edin., M.R.C.S., Certifying Surgeon under the Factory Act for the Yeovil District of the county of Somerset.

MARSHALL, J. COLE, M.B., F.R.C.S.Eng., Clinical Assistant to the Chelsea Hospital for Women.

SNELL, SIDNEY H., M.D., B.S.Lond., Assistant Anæsthetist to the Royal Ear Hospital, Soho.

Births.

SURRIDGE.—On February 19th, at Knutsford, Cheshire, the wife of E. N. Surridge, B.A., M.B., B.C., of a daughter.

Marriages.

WARNER—ADCOCK.—On February 15th, in London, Charles I. Warner, of Somersham, Huntingdonshire, to Clara, second daughter of the late Dr. and Mrs. Adcock, of Hunstanton, Norfolk.

Deaths.

BROWN.—On February 17th, at Dovedale, Wimblehurst Road, Horsham, Augustus Brown, M.D., in his 76th year.

DRESCHFELD.—On February 20th, Selma, dearly-beloved wife of Julius Dreschfeld, M.D., of 43, Leyland Road, Southport.

HIND.—On February 16th, at Blytheholme, Harrogate, Annie Charlotte, wife of Henry Hind, F.R.C.S.

MACLEOD.—On February 17th, at 18, Mornington Avenue, W., Inspector General of Hospitals and Fleets William MacLeod, M.D., C.B., R.N. (Retired), aged 84.

PRICE.—On February 14th, at Cheltenham, Jane Stacpoole, younger daughter of the late William F. Price, M.D., of Monmouth.

TULLOCH.—On February 19th, at Brighton, Isabelle Maynard, younger daughter of the late James Tulloch, M.D., Pembridge Place, Bayswater.

Original Communications.

THE DIMINISHING BIRTH-RATE: ITS CAUSE, ITS TENDENCY, AND POSSIBLE REMEDY. (a)

By JOHN W. TAYLOR, M.D., F.R.C.S.,

Professor of Gynæcology in the University of Birmingham; President of the British Gynæcological Society.

PART I.

GENTLEMEN,—The Presidency of the British Gynæcological Society is an honour which I fully appreciate, and which I would simply and heartily acknowledge. This Society, from its beginning, has been truly British in its scope and interests. It has freely and graciously recognised the work and claims of the Provinces as well as those of the Metropolis; and in representing to some extent, however unworthily, the work and claims of Birmingham and the Midlands, I do joyfully appreciate the place held by us in the heart of the Society, and in the very centre of its labours.

As I enter upon my duties this evening, I do so with a sense of great responsibility; and this is undoubtedly increased by the recognition of the difficulty and yet immense importance of the subject which I have chosen for my Inaugural Address. This—"The Diminishing Birth-rate, and what is involved in it"—I purpose now to deal with, trusting I may count on that consideration, sympathy and interest which so serious an undertaking may reasonably demand.

I.

In one of the chapters of Mr. Ruskin's well-known book on Political Economy, "Unto This Last," he deals with an inquiry into what he calls the "veins of wealth." He exposes the fallacy that the wealth of a State lies solely or essentially in material possessions—showing that apparent or nominal wealth which fails in its authority over men, fails in essence and ceased to be wealth at all—that the true veins of wealth are, as he says, "purple—not in rock but in flesh," and the "final outcome and consummation of all wealth is in the producing as many as possible full-breathed, bright-eyed, and happy-hearted human creatures."

In his final chapter, "Ad Valorem," Mr. Ruskin writes:—"There is no wealth but life. That country is the richest which nourishes the greatest number of noble and happy human beings"—"the nobleness being not only consistent with the number, but essential to it. The maximum of life can only be reached by the maximum of virtue."

The principles or truths contained in these passages—passages which bear the strictest examination and criticism—may be, and are, very generally accepted, theoretically. But the history of the nation during the last twenty-five years shows that the principles which govern its real life are altogether different and directly contradictory.

To-day, we are brought face to face with unanswerable statistics proving that our birth-rate is steadily diminishing. This has already attracted the serious consideration of statisticians and of some of our statesmen, but the inquiry into its causes has been confused and incomplete. Here, I hope, we can at least discuss these plainly and fearlessly, for some of the problems connected with causation are essentially gynæcological, and can, perhaps, only be rightly gauged by those who have special medical and gynæcological experience.

The subject is a great one—so great, indeed, that if the nation could only see it in its true proportion, it would, I think, be found to dwarf all other questions of the day.

I cannot hope in the time at my disposal to enter fully into all its phases. I do hope, however, to take the most salient and striking features of the statistical data at our command, to inquire what is meant and involved by these, and to consider how far the profession and the public may do anything to check the apparently relentless progress of an evil destiny.

The best tables for our primary consideration are some of those which have been compiled by Mr. Holt Schooling, the statistician. In Table I we see the average yearly number of births to each thousand persons living in the United Kingdom during five successive periods of five years each.

Table I.—The average yearly number of births per 1,000 persons living in Great Britain and Ireland, during the 5-yearly

Periods.	
1874–1878	34·3
1879–1883	32·6
1884–1888	31·2
1889–1893	29·8
1894–1898	29·1

(Note the steady decrease, 34, 32, 31, nearly 30, 29, and in 1901 it had come down to 28.)

Now let us compare this with exactly similar statistics of other countries:—

Table II.—The average yearly number of births per 1,000 persons living during the 5-yearly

Periods.	Austria.	Germany.	Italy.	Great Britain and Ireland.	France.
1874–1878 ..	39·4 ..	40·1 ..	37·0 ..	34·3 ..	25·8
1879–1883 ..	38·4 ..	37·5 ..	36·8 ..	32·6 ..	24·8
1884–1888 ..	38·1 ..	36·9 ..	38·2 ..	31·2 ..	23·9
1889–1893 ..	37·1 ..	36·3 ..	36·9 ..	29·8 ..	22·5
1894–1898 ..	37·3 ..	36·1 ..	34·9 ..	29·1 ..	22·3

If we compare the top line with the bottom we see that in each case there has been a fall, so that a diminishing birth-rate is not a feature of our own Kingdom only, but is to some extent European in its scope or effect, and the lowest birth-rate is that of France.

Of the other great powers and nations—the United States, Russia, China, and Japan—no certain statistics are available, but we have very good reason to believe that the birth-rate is seriously falling in the States, but notably rising in Russia and Japan. According to Russian statistics from 1892-1894, the birth-rate per 1,000 was 47·7, and from 1894-1897 the birth-rate

(a) Inaugural Address read at the meeting of the British Gynæcological Society, Thursday, February 11th, 1904.

per 1,000 was 49·5, so that there has been not only no loss or diminution in the birth-rate here, but the figures are also far above those already tabulated. So far, the data we have considered show us that the birth-rate throughout the whole of the West is diminishing, while that of the East is rather expanding.

We now want to consider the relative birth-loss of the various Western nations as compared with one another, and this brings us to the most important and startling of Mr. Schooling's tables.

He takes the birth-rate statistics for 1874-1878 in each European nation as the standard for that nation, and places against this the statistics for 1894-1898, computing from this the loss of birth-force in the twenty years. The following is the result :—

	The yearly birth-force during 1874-1878 taken as	The yearly birth-force during 1894-1898 was only	The percentage of yearly loss during 1894-1898 was
Norway	100	96	4
Denmark	100	95	5
Austria	100	95	5
Italy	100	94	6
Hungary	100	91	9
Germany	100	90	10
Switzerland	100	90	10
Belgium	100	89	11
Holland	100	89	11
Sweden	100	88	12
France	100	86	14
United Kingdom	100	85	15
England and Wales	100	83	17

In other words, while Norway, Denmark and Austria very nearly keep up their birth-force of twenty years ago, the other nations in their order show an increasing loss, and England and Wales stand at the very bottom of the list. None of the other nations have sustained so great a loss as we have in this definite period of time.

During the same period of time the marriage-rate in the United Kingdom has not altered much, but, during the last ten years or so, has been slowly rising. The figures in the returns of the Registrar-General are as follows (Table 44, 1900) :—

	Persons married to 100 living.
1876–1880	14·2
1881–1885	14·1
1886–1890	13·8
1891–1895	14·3
1896–1900	15·2

So that we may take the birth-loss in the United Kingdom as due to causes operating in the married life of its inhabitants. It is not simply due to celibacy.

The fertility of marriages appears to have so much diminished that the decrease in London alone is said to "equal 26,000 births yearly, or about 500 weekly." (Mr. T. A. Welton at a meeting of the Royal Statistical Society, June 17th, 1902.)

But some may say, England and Wales are only a small part of the Empire, and the statistics of Great Britain, where there is but little room for expansion and increase, form no criterion of the birth-rate in our Colonies. Unfortunately, what statistics are available on this point, and notably those of Australia, offer no encouragement to the hope that the Colonies are much better than ourselves.

In Australia the birth-rate has fallen with an even still greater rapidity than in England. In 1861-1865 the rate was 41·9 per 1,000, but had diminished in 1871-1875 to 37·3; in 1881-1885 to 35·2; and in 1891-1895 to 31·5; while in 1896-1899 the rate was only 27·35, or actually below the rate of increase at home. If we work out these figures in harmony with Table III we find Australia a long way below all the European nations, with a birth-force down to 70·3, and a percentage of yearly loss amounting to nearly 30!

Regarding this, Mr. H. W. Wilson writes :—"The decline in Australia is great in every position of life, among the poorest and the richest alike, and it is the more extraordinary because the greatest want of Australia is a teeming population."

But any statistical inquiry, to be of value, must be considered in all its bearings. It has been said, and with considerable reason, that there is nothing so unreliable as statistics, and this may be the case when these are imperfectly considered. In the present instance, if we are desirous of estimating the true wealth or value of the population we possess, there may be a fallacy in mere numbers. It may well be that twenty children better clothed, better fed, better educated, better trained, may develop into men higher socially and morally, stronger and better able to hold their own than 100 children less advantageously brought up. Can we hope that the type of man is improving?—that the generation of Englishmen to-day, though falling short in birth-force, is yet greater than the generation preceding it?

Again, unfortunately, we must sorrowfully admit that we have no sufficient ground for believing this. The criminal statistics, though showing a general and steady reduction in the whole criminal population of the United Kingdom, during the last twenty years (a fact which is very encouraging), do *not* show a corresponding diminution in juvenile criminality, and it is necessarily the youth of our country to which any estimate of the last twenty-five years would more particularly apply.

According to August Brähms, in his work on "The Criminal" (p. 272), "Juvenile criminalism is on the increase. Forty per cent. of the convictions in England every year are against young persons under twenty-one years of age." And on page 281 he appends a table which shows a higher percentage of criminals under twenty years of age in England than in any of the other European countries there tabulated.

The Lunacy statistics of England and Wales show a steady proportionate increase of lunatics and idiots, especially during the last few years.

In 1869 there were 23·93 lunatics, idiots and persons of unsound mind to 10,000 of population.

	1879	27·54
5 years.	1889	29·65
	1894	30·58
	1899	32·96
	1903	34·14

(From the 57th Report of the Commissioners in Lunacy, 1903. Parliamentary Blue Book.)

Or, in other words, the increase of lunatics and idiots in England and Wales has, during the last fifteen to twenty years, been very nearly double the old rate.

The natural deduction from these figures that insanity and idiocy are increasing seems also to be proved by the recent statistics of the new admissions to asylums and licensed houses. The ratio of first admissions to 10,000 of population has been as follows :—

In 1899	4·94
,, 1900	5·02
,, 1901	5·28
,, 1902	5·76

(*Ibid.*, p. 95.)

It is very difficult to obtain trustworthy statistics regarding alcoholism, but those given in the "Temperance Problem," by Messrs. Rowntree and Sherwell, are probably the best. According to these the consumption of wine per head of the population has varied but little during the twelve years from 1885 to 1897, but, during the same time, the consumption of beer has gone up from 27·5 gallons to 31·3 gallons, and of spirits from ·93 gallons to 1·02 gallons. And the "national drink bill" (p. 437), which was estimated at £3 7s. 10d. per head in 1885, came to £3 16s. 10½d. in 1898. In London (Metropolitan Police Area) there were, from 1885 to 1889, 4·33 arrests for drunkenness to 1,000 of the population. In 1897 the proportion had risen to 7·35 (p. 499).

So, in juvenile criminalism, in mental disease and brain weakness, and even in alcoholism, the restricted population of the present day compares unfavourably with that of a former generation.

If we try to go on and trace this comparison further,

and compare the general culture of the more intellectual classes of the two generations over a limited field—for no general statistics are available—still the investigation (though necessarily imperfect and tentative) seems to point to an unfavourable conclusion.

In my own city of Birmingham, a critical survey of its chief semi-public literary and artistic institutions has been recently made by Mr. Howard S. Pearson, and he publishes a tabulated statement showing the support given to these twenty years ago, ten years ago, and to-day. (*Central Literary Magazine*, Nov., 1903.)

His figures show as a net result that in the course of twenty years there has been a loss of 366 subscribers, or about one in fourteen. "This would be discouraging, but it is by no means all. The population of the city and district has vastly increased, while this care for intellectual and artistic culture has materially diminished. In brief, the population has increased by more than one-fourth, while the interest in the institutions named has decreased by one-fourteenth." Later on, Mr. Pearson writes:—"These institutions are not some among many; they have actually no rivals at all. Neither in the city nor in the neighbourhood is there anything which even pretends to touch their special work. They stand, each in its own way, for the general and intellectual culture of the educated classes. The very aim and intent of all our strenuous efforts in the cause of education is to increase the proportion of the educated classes and to lead to a life-long interest in culture. And as the population rises, as education becomes more far-reaching, as art is more and more talked about, even so must grow the discouragement of all who might have hoped to gather from the changed conditions a large sympathy in their work."

It must be confessed that the more deeply and thoroughly one goes into this matter the more serious does it become. Prof. Karl Pearson (Huxley Memorial Lecture, 1903, and *British Medical Journal*, October 24th, 1903), who has approached it from an altogether different standpoint—from a careful study of the inheritance by children of the mental and moral, as well as the physical characters of their progenitors—comes to much the same conclusions. He notes that there appears to be a want of intelligence in the British merchant, workman and professional man of to-day, and sees but little hope in the usually proposed remedies of foreign methods of instruction and the spread of technical education. "The reason for the deficiency," he states, "is that the mentally better stock in the nation is not reproducing itself at the same rate as of old—the less able and the less energetic are the more fertile. Education cannot bring up hereditary weakness to the level of hereditary strength, and the only remedy is to alter the relative fertility of the good and bad stocks of the community. The psychical characters which are the backbone of a State in the modern struggle of nations are not so much manufactured by home and school and college; they are bred in the bone, and for the last forty years the intellectual classes of the nation, enervated by wealth or by love of pleasure, or following an erroneous standard of life, have ceased to give in due proportion the men wanted to carry on the ever-growing work of the Empire."

All this tends to show that the marriages of to-day are not only relatively infertile, but, also, either (1):—that the children born of such marriages are weak, neurotic, specially liable to alcoholism, criminality and insanity, and so far unfit for the battle of life, or, (2) that marriages of the middle and better classes are now so sterile that quite an undue and dangerous proportion of the rising generation is recruited from the lower, the more ignorant, the more vicious and semi-criminal population.

In any case the conclusion is one of the utmost gravity, and almost paralysing in the seriousness of its import. It is indeed a "handwriting on the wall" which claims the fullest and wisest interpretation to be found throughout the Kingdom.

II.

We now pass on to the consideration of the cause and life-history of these relatively sterile marriages. Some, and notably M. Arsène Dumont, in his work on the age of marriage, profess to consider the elevation of the age when marriage is entered into as mainly responsible for the deficit in the birth-rate. It does undoubtedly account for some of the loss. Obviously, if marriage be deferred until thirty-five or forty years of age, there must be less expectation of progeny than in a marriage contracted some ten years earlier. It is, however, idle to suppose that this touches more than the fringe of the nation's loss. The main cause, and we who are in gynæcological practice must know it, is the deliberate prevention of conception. This, which was first encouraged and taught in England some thirty-five years ago, has gradually spread like a blight over the middle-class population of the land, and the true wealth of the nation, the "full-breathed, bright-eyed, and happy-hearted children" of Ruskin, have more or less gone down before it. It is this which has so altered the family life of our country that the most superficial observer of middle or advancing age must be struck by the difference. Instead of the families of six or twelve to eighteen children, we see more often the so-called family of three or two or one, and that which used to be—and still should be—the highest and noblest function of the married woman, the rearing of sons and daughters to the family, the nation and the Empire, is very largely handed over to the lower classes of our own population and to the Hebrew and the alien.

For a long time it appears to have been assumed that whatever might be the loss to the nation and the race by such a practice, the individual must gain. The avoidance of the troubles of pregnancy, the dangers incidental to parturition, the confinement of the lying-in, the worries of lactation, the expense of another child, and the extra work which this entails—all of this avoided seems at first to be an undoubted gain to the struggling husband and over-anxious wife, and it would ill-become me, with the knowledge I possess, if I failed to appreciate the difficulties of the position or to under-estimate the power of that current advice which seems only to be dictated by common prudence.

But the question arises whether this immunity from pain and trouble may not be too dearly purchased, even by the persons themselves who are primarily concerned.

It would be strange indeed if so unnatural a practice—one so destructive to the best life of the nation—should bring no danger or disease in its wake, and I am convinced, after many years of observation, that both sudden danger and chronic disease may be produced by the methods of prevention very generally employed.

In one or two instances I have known acute peritonitis to immediately follow the use of an injection after sexual intercourse. The cervical canal appears to be often unusually patent at this time, and the danger is neither an unimportant nor isolated one.

In another instance I was consulted for an acute purulent vaginitis directly following the use of a mechanical shield, and as both parties were free from any disease previously, there could be no doubt that the infection or cause of irritation arose from this.

These are casual instances of sudden danger or acute illness that have come under my own notice, but none the less real and far more common is that chronic impairment of the nervous system which frequently follows the long-continued use of any preventive measures, whether open to hostile criticism or not as immediately dangerous.

This chronic impairment of nervous energy of which I am now speaking, often referred to under the name of neurasthenia, and still more recently under that of "brain-fag," has many causes, and may be produced whenever there has been too great a tax or drain upon the nervous system, and too short a time for real recuperation; but it is especially marked in many of these cases of sexual onanism.

The inability to fix attention, the unreasonable fears, the loss of memory, the loss of emotional control, the mental depression and abject misery often felt by

the sufferer—himself or herself—and shown more or less in countenance, word and act, these are symptoms well known to all of us, and symptoms that may be studied exceptionally well perhaps in the school-boy addicted to the habit or vice of self-abuse. With the reform of this habit in the boy, all of these symptoms quickly disappear. It is difficult, therefore, to escape from the conclusion that the storing-up of semen in the male is of value in the economy. It is undoubtedly a source of strength both in man and in the lower animals, and it appears as if the seminal fluid must therefore have some function beyond and in addition to its power in the reproduction of species. Its loss is often followed immediately by loss of strength and staying power, and this loss of strength or vitality after the process of reproduction is noticeable throughout all the animal creation, man being no exception to the general rule.

Further, the artificial injection of "testicular juice" in senility, though a means of treatment by no means free from objection, and one of which I have no personal knowledge, is stated by many competent observers (from Brown-Séquard to Boy Teissier in the "Twentieth Century Practice of Medicine") to be attended by very marked results, and this, I believe, quite irrespective of the sex of the patient submitted to the treatment. (*a*)

Do we understand the whole of the physiology of the act which often ends in conception? Is it limited, as most have too readily assumed, to the carrying of spermatozoa for the fecundation of the ovum, or is some portion of the fluid retained by the uterus and absorbed?

Modern investigation shows that traces of the seminal fluid may be found quite high in the female genital tract, beyond the confines of the uterus, and the ever varying mucous surface of the body of the uterus can, as we know, under certain conditions easily absorb septic poisons and mercurial salts.

Beyond this, it is by no means certain that the endometrium and so-called uterine glands are inactive. Except during menstruation there is no visible discharge from the body of the normal uterus, and if the theory of Arthur Johnstone be accepted, that the cavity of the corporeal endometrium is essentially an open lymph-gland, the channel of absorption may be immediate and direct.

It is quite possible, then, that in one or both of these suggested ways some tonic constituent of the seminal fluid may be taken up by the uterus, and thus affect the general organism; and there is nothing unreasonable in the suggestion that such absorption may allay the exhaustion which, without it, is liable to follow the act of connection.

It is very noticeable that exactly the same train of neurasthenic symptoms are nearly always to be observed in the worst cases of cervicitis, where the cervical canal is effectively plugged by thick mucus, and the patient, though married, is temporarily but necessarily sterile. In both cases the resulting imperfect acts of sexual congress appear to be directly harmful.

But apart from this, is the prevention of pregnancy the gain to the woman that so many imagine? It may well be questioned whether in the study of pregnancy sufficient attention has been paid to the period of ovarian rest which appears to accompany the growth of the pregnancy. The raising of the ovaries out of the pelvis into the abdomen, the diversion of the main blood stream for nine months directly to the uterus, and the absence of menstruation, through pregnancy and lactation, argue a time of rest and comparative inactivity for the ovaries which cannot but have an important value in the life of the woman who is married, and at the same time physiologically ready for conception and for pregnancy.

During this time of uterine activity, but of ovarian rest, there is ample opportunity for the nervous supply of the ovary to recover from any undue stimulus, and it is perhaps worthy of notice that this period is usually attended by improvement in general nutrition and increase of fat. This comparative suspension of ovarian activity also coincides with the time when the uterus is filled and unable to retain the secretion of the male.

When this period is fully over it is only reasonable to suppose that the ovaries have gained by this alternation in the sexual apparatus, and that the maturation of the follicle may proceed more healthily, and even the ovum itself may be more perfectly formed, than in the case of a woman in whom this natural cycle has been artifically prevented. In this case the ovaries suffer and the woman suffers with them—far more, as a rule, than she would by repeated child-bearing. Widely as the practice of prevention has spread you will still have to go to the mothers of large families if you want to point to the finest and healthiest examples of advanced British matronhood. The natural deduction from this reasoning is, that the artificial production of modern times—the relatively sterile marriage—is an evil thing even to the individuals primarily concerned, injurious, not only to the race, but to those who accept it.

Much that I have said regarding the married life of the mothers of our race has a very similar bearing on that of the fathers also. The incomplete act of sexual congress is but slightly removed from that of self-abuse, and is open to much the same criticism and strictures. The lower passions are usually stronger in man than in woman, and demand a firmer control. This is encouraged by the natural progress of the healthy married life. The recurring periods of abstinence and restraint induced by each pregnancy, at the confinement and lying-in, not only tend to raise the man himself, but the power obtained by this we may expect (as Prof. Pearson has demonstrated regarding other moral faculties) to be mathematically transmitted to his children.

The increased work and self-sacrifice also necessitated by the growth of the family, the simpler and plainer standard of life corresponding to this, all have their ennobling effect on parents and children. But when the opposite of this obtains then, indeed, there follows not only a moral deterioration of the individual but a step has been taken reversing the great order of progress from the brute. For then the higher powers of the race, knowledge and the intellectual application of it shown in "prevision" and "precaution" have become systematically subservient to the lower and the animal. And when this is the case decadence has begun.

There is no method of prevention, whether by withdrawal or by the use of injections, or shields, or medicated suppositories, that can be regarded as innocuous.

The health, and especially the mental and moral stamina, of those who use these "checks" is slowly undermined. The very life of the nation, as we have seen, is seriously imperilled, and there is increasing reason to believe that such isolated children as are "arranged for" and produced under these conditions may themselves suffer and be degraded by their antecedents.

To the evils of disease, race-limitation, or destruction and hereditary weakness which appear to inevitably follow the artificially sterile marriage, we have to add the accompanying evil of a debased and stunted education for the children.

In the most plastic period of the child's life, in its earliest years, the more or less solitary child brought up in a land of solitary children is necessarily isolated and self-centred. Reared in greater comfort or comparative luxury, with no brothers or sisters of similar age to rub off its angles and selfishness, it is ill-prepared for every step of the succeeding battle of life, and it is very generally the child of the larger family and poorer parents, and very often the child of a lower class, who pushes his way in front of him and elbows

(*a*) Dr. Boy Teissier writes:—"I have employed injections of testicular juice in certain cases of irregular and sometimes very advanced senility, and the very favourable results thereby obtained are of such a nature as to make me regard this substance as an agent of real power the employment of which is rarely contra-indicated.

him to the wall. I have no time to dwell on this, which opens out an important field for further observation and study, but you, gentlemen, who have necessarily been students of human nature all your lives, will know how much there is to bear out every word that I have said.

(To be concluded in our next.)

PUBLIC HEALTH PROBLEMS IN IRELAND. (a)

By SIR JOHN W. MOORE, M.D., D.P.H.Univ. Dub., F.R.C.P.I.,

President of the Section of State Medicine in the Royal Academy of Medicine in Ireland.

ON February 5th, 1885, I addressed this Section—or, as it was then, Subsection—of the Academy on "Sanitary Organisation in Ireland in its Medical Aspect." Two years later, on February 3rd, 1887, the subject of my Inaugural Address was "The Present and the Future of State Medicine."

In the seventeen years which have passed away since the latter date, State Medicine has made unexampled progress in all its departments; sanitary organisation in Ireland, on the contrary, has advanced "with halting steps and slow." Yet substantial advance has taken place in many directions even in this country.

Notification.—In 1887 I had to deplore an uncompromising opposition to the principle of compulsory notification of infectious diseases on the part of the vast majority of the medical profession. On August 30th, 1889, an "Act to Provide for the Notification of Infectious Disease to Local Authorities" (52 & 53 Vict., chapter 72) received the Royal Assent. All opposition to the principle of notification has long since happily died out, and the Act has now been adopted practically throughout the length and breadth of the land, with untold benefit to the public health.

The provisions of the "Infectious Disease (Notification) Act, 1889," are too well known to need any explanation at my hands. I may, however, refer to a useful application of the Act, whereby comparatively trivial infections which simulate more serious maladies, like chicken-pox in its relation to small-pox, or rubella in its relation to measles or scarlatina, are temporarily added to the schedule of notifiable diseases when the more deadly infections threaten to be, or are, epidemic.

On August 4th, 1890, an "Act to Prevent the Spread of Infectious Disease" (53 and 54 Vict., chapter 34), shortly called the "Infectious Disease (Prevention) Act, 1890," was put upon the Statute Book, with the object of enabling sanitary authorities to give practical effect to preventive measures based on information obtained through notification.

These two measures—the Magna Charta of Public Health—have been cordially received by the medical profession, who with a noble self-denial have once more admitted the truth of the adage—*Salus populi suprema lex.*

Qualifications in Public Health.—A second great advance has been the official recognition of diplomas in State Medicine or Public Health. The initial step had been taken in 1886, when the Medical Act (49 and 50 Vict., chapter 48), by its twenty-first section, provided for the registration by the General Medical Council of Diplomas in Sanitary Science. Since January 1st, 1892, the medical officer of health of a county, district or combination of districts with a population of 50,000 or upwards, must, in addition to his qualifications in medicine, surgery and midwifery, be registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act of 1886. It is gratifying also to note how many officers in the naval, military, and Indian Medical Services are taking this higher qualification. In my address to this Section in 1887, I recalled the fact that to the University of Dublin belongs the credit of having been the very first institution in the United Kingdom to establish a diploma in State Medicine, or (as it is now called) "Public Health." The first examination for the diploma took place in June, 1871—nearly thirty-three years ago, when it was granted to Dr. Arthur Wynne Foot, Dr. Gerald Francis Yeo, Dr. John Todhunter, and myself.

Tuberculosis and its Prevention.—A notable contribution to the literature of this all-important question has been recently published. I refer to an article in *Tuberculosis* for January, 1904, on "The Present Position of the Tuberculosis Problem in Ireland," by Dr. Alfred E. Boyd, Honorary Secretary of the Dublin Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. Dr. Boyd shows by figures taken from the Annual Report of the Registrar-General for Ireland for 1902, that the deaths from tuberculosis in Ireland in that year were 11,837, against 12,335 in 1901, and an average of 12,716 in the ten years 1891-1900. Phthisis, or pulmonary consumption, was responsible for 9,400 deaths in 1902. The highest county death-rates for tuberculosis in general for the same year are—Dublin County Borough, 4·7 per 1,000 of the population annually; Belfast County Borough, 4·0; Dublin County, 3·5; Cork County and Cork Borough, 3·0; The lowest rates are—Cavan, 1·5; Roscommon, 1·6; Mayo, Fermanagh, Longford, and Donegal, each 1·7.

For the whole country the deaths in 1902 represent an annual death-rate of 2·7 per 1,000 of the population—the lowest rate recorded in Ireland since 1896. Commenting on these figures, Dr. Boyd observes: "The upward tendency, which during recent years has caused grave anxiety, has thus been checked, and there is ground for hope that ere long there will be a substantial decrease in the prevalence of tuberculous disease in Ireland."

Having described what has already been done in Dublin to cope with the evil, Dr. Boyd set forth the chief measures still required, in order to control tuberculosis. These will be found in the article above quoted.

The Housing of the Poor.—Closely connected with the prevention of tuberculosis is the question of the housing of the working classes and of the very poor—a burning question in Dublin of late years. It will be within the recollection of the Fellows that in 1900 the Local Government Board for Ireland appointed a Committee to inquire into the public health of the City of Dublin. In their report, dated May 14th, 1900, the members of that committee speak of "large tenement houses, each room occupied by a separate family; the house itself in a state of dilapidation; water supply inconvenient of access; dirty common staircases; inadequate water-closet accommodation in a foul state; back-yards ill paved and littered with refuse and excrement, are conditions of life in Dublin which are frequently encountered in connection with the dwellings of the poorer classes." The committee point out that these conditions tend to produce a state of lowered vitality favourable to the contraction of disease, and to a fatal result of disease when contracted. They also directly encourage the spread of infective maladies, including phthisis and other forms of tuberculosis, which are excessively prevalent in a fatal form in Dublin. Strict cleanliness in the home is of the first importance in checking the spread of consumption, and cleanliness finds no place in most of the houses occupied by the Dublin poor. And in this connection it has to be borne in mind that the proportional amount of poverty in Dublin is very large, so that the unfavourable conditions associated with the houses of the poor are widely spread throughout the city.

The committee go on to state that "the question of the housing of the poor of Dublin is one of magnitude. The provision of an adequate number of healthy dwellings by way of relief for the present overcrowding of population under unhealthy conditions must, of necessity, be on a considerable scale, and would probably involve several schemes. Sites for the provision of dwellings for the poor could best be obtained outside the city, in localities within easy reach of the principal

(a) Abstract of an Address inaugurating the Session of 1903-1904, delivered before the Section of State Medicine in the Royal Academy of Medicine in Ireland, Friday, February 12th, 1904.

business quarters of Dublin. In these schemes it should be borne in mind that healthy dwellings are especially needed in Dublin for the very poor. Houses, therefore, intended with this object should be of the plainest kind, in order that such schemes may not entail heavy loss upon the ratepayers.

As to the last point, we must remember that anything which will reduce the liability to epidemic disease will be a direct saving to the ratepayers. It was calculated that the small-pox outbreak of 1878 cost the city of Dublin not less than £20,000 sterling.

In the paper from which I have already quoted Dr. Boyd points out that much has been done, and is being done, in Dublin to mitigate the evil of overcrowding. The Dublin Artisans' Dwellings Company, the Iveagh Trust, and the Corporation of Dublin "have erected modern buildings on sites which were formerly covered by houses in which sanitation was too often primitive, and in which healthy existence was almost impossible; while the Association for the Housing of the Very Poor, the Social Service Tenements Company, and the Alexandra Guild have, in a smaller way, attacked the problem by buying buildings which were capable of renovation, rendering them sanitary, and letting them to the poor at rents which cover expenses, and in some cases allow of a small rate of interest being paid on the capital invested." The Social Service Tenements Company is worked by students and others connected with Trinity College, Dublin. The Alexandra Guild is connected with the Alexandra College, Dublin, an institution for the higher education of women. The Urban District Councils of Rathmines, Pembroke, Kingstown and Blackrock are also engaged in extensive building operations for the better housing of the working classes and the poor. In the very heart of the city the space between the ancient cathedrals of Christ Church and St. Patrick has, within the past few years, been changed by a magician's wand. A charming park and wide, well-paved streets, with airy, well-built houses, have taken the place of squalid lanes and alleys, reeking with filth and hot-beds of disease—typical "fever-nests," such as were so graphically described by the late ever-to-be-lamented philanthropist and sanitarian, Dr. Thomas W. Grimshaw, C.B., Registrar-General for Ireland. In many other districts also, both north and south of the River Liffey, wholesome homes for the industrious working classes have sprung up under the auspices of the Dublin Artisans' Dwellings Company. "Old Dublin" is, in fact, rapidly disappearing and with it typhus fever has already well-nigh disappeared.

Workhouse Reform.—I wonder whether at the present time a single champion of the existing Poor-law system of Ireland could anywhere be found? In the first place universal suffrage and the Local Government (Ireland) Act of 1900 have flooded the boards of guardians all over the country with "representatives" of the sovereign Plebs. In many instances these men are, from the accident of their birth, social position, calling and education, incapable, however well-meaning they may be, of discharging their duties to the poor and infirm in an enlightened philanthropic spirit, untrammelled by political and sectarian considerations. A single instance by way of illustration must suffice:—The medical officer of Granard Workhouse—himself a Roman Catholic—complained that his patients were not being properly nursed. The nurses were nuns, the rules of whose sisterhood forbade them carrying out certain details of sick nursing. What was the result? The Sisters resign. The Bishop of the diocese espouses their quarrel. An unseemly wrangle between the Local Government Board and the guardians ensues, and drags on for months. The Bishop insists on an apology to the nuns by the medical officer, who did nothing more than his duty. And so the interests of the sick poor are wantonly sacrificed.

But matters are even worse when we come to consider the internal economy of the workhouses of our land. As it exists, it is a grave scandal and a national disgrace.

"The workhouse system," says Miss Emily Bunan (herself a Poor-law guardian), in a paper read by her before the Philanthropic Reform Association on September 22nd, 1903, "is unjust and distasteful to the sick and helpless classes, and is only too attractive to the undeserving who thrive upon its corruptions. In no other country in Europe, outside the United Kingdom, is such a system to be found."

Reform should proceed on such lines as the following:—

1. All children should be boarded out, and properly educated.

2. The respectable aged poor should also be boarded out. In Denmark there are asylums apart from the workhouses for the reception of old men and old women who, through no fault of character, but by reason of advancing years and failing powers, have been reduced to penury. In these asylums they find a comfortable home and retain their self-respect.

3. No lunatics or epileptics should be admitted to the workhouse. This is the law in England and Scotland.

4. The union hospital or infirmary should be entirely separate from the workhouse; nor should the hospital patients be drafted into the workhouse when convalescent.

5. It is desirable that women inspectors should be appointed under the Local Government Board. The principle of such an appointment has already been admitted in regard to boarded-out children. To the Irish Workhouse Association, headed by its noble President, Lord Monteagle, is due the credit of initiating this great reform.

6. The employment of fully-trained nurses should be compulsory on all boards of guardians.

These are some of the lines along which Poor-law reform should move.

The Poor-law Medical Service.—At last—after long years of unaccountable apathy—the medical profession appears to be awaking to a sense of the grave and most unsatisfactory state of what may be called "the home medical service." The lot of the average dispensary medical officer in Ireland is, of a truth, not an enviable one. Overworked and underpaid, at the beck and call of masters, whose views as to his duties and their rights are not always controlled by that "sweet reasonableness" which is begotten of a liberal education and a ripe experience of the world; hampered in his ministrations to the sick by official bookkeeping; with no prospect of promotion after years of toil and drudgery; face to face with the conviction that he must die in harness, or run the risk of retirement without pension or "superannuation"—what a calling for a member of a "learned profession"!

It is, however, in the aspect of the question which bears on the sanitary organisation of the country that the interest of the State Medicine Section of the Royal Academy mainly centres. The members of the Section will remember that every dispensary medical is *ipso facto* medical officer of health for his dispensary district. He is *obliged* to perform many and onerous duties, which are specified in detail in an order to sanitary authorities issued by the Local Government Board under the Public Health Act of 1878. Additional duties have been imposed upon him by subsequent Acts of Parliament, such as the Labourers' Dwellings Act (1890 and 1893); the Infectious Disease Notification Act (1889); the Infectious Disease (Prevention) Act, 1890; the Public Health Amendment Acts of 1884 and 1885; the Housing of the Working Classes Act of 1890; and the Local Government (Ireland) Act of 1898.

For these multifarious and highly responsible duties a shamefully inadequate remuneration has been fixed at the instigation and with the approval of the Local Government Board for Ireland. The sanitary authorities are no doubt to blame for having so grievously misjudged the value of skilled services rendered to preventive medicine by the local medical officers of health; but the chief fault lies at the door of the central controlling authority—the Local Government Board, which should have refused to sanction mere nominal salaries to medical officers of health whose duties were bound to be anything but nominal unless the

administration of the public health code in Ireland was to be a sham.

As has been already stated, in the year 1900 the Local Government Board for Ireland appointed a committee to inquire into the public health of the city of Dublin. I had the honour to serve on that committee, and I need not say with what deep regret I felt bound, after hearing an immense mass of evidence, to subscribe to the following finding of the committee:—"The evidence laid before us leads to the belief that the provision of Section 11 of the Public Health (Ireland) Act, 1878, whereby each dispensary medical officer is obliged to act as medical officer of health for his dispensary district, has worked unsatisfactorily in Dublin, and should be altered."

Let me not be misunderstood. The committee found no fault with the way in which the duties of medical officer of health had been discharged by the sixteen dispensary medical officers of the city of Dublin districts. Quite the contrary. Their conduct has been on all occasions most praiseworthy, self-denying and devoted. But their executive power existed only in name; they could do little more than report; they were little better than "sanitary sub-officers"—to quote the ridiculous nomenclature of the eleventh section of the Public Health Act of 1878; the many claims upon their time as district physicians curtailed their usefulness as health officers.

Effect, however, has not been given to the recommendation of the committee that the public health duties of the dispensary medical officers "should be discharged by an assistant medical officer of health, who should receive an adequate salary, and who should give his whole time to the duties of his office." In Dublin, as throughout Ireland, the dispensary medical officers remain the medical officers of health for their respective districts, and what I now contend for is that this hard-worked, badly-requited body of public servants, whose efforts for the health and welfare of the community are often misunderstood, seldom, if ever, appreciated, should be properly recompensed for their services under the Public Health Acts. If this is done, and if the suggestions for the betterment of the health of the people, made by the local medical officers, are carried out intelligently and in a generous spirit, the dawn of a brighter day for the Irish race will at last be at hand.

NEW TREATMENT OF RENAL AND CARDIAC DROPSY. (a)

By PROFESSOR RENAUT, M.D.,
of Lyons.

WE have already referred briefly to the new departure in the treatment of renal and cardiac dropsy recommended by Prof. Renaut, of Lyons, consisting in the administration of macerated pork kidneys, on which he read a paper at the meeting of the Académie de Médecine, Paris. The great importance of the subject and the remarkable results obtained merit more than a passing notice, consequently we think it right to reproduce the paper as fully as possible.

After some preliminary observations on the method of administration, Prof. Renaut gave the following cases with results:—

Case I.—Old-standing nephritis, bronchitis, albuminuria, and œdema of the extremities in 1902, attack of renal insufficiency with œdema and uræmia in January, 1903. Restitution of the normal diuresis and disappearance of the albuminuria from May, 1903, and continued up to the present time.

D——, æt. 56, living in the country, heavy eater, but not alcoholic. Frequent attacks of bronchitis since 1901. Slight œdema of the legs, œdema of the base of both lungs, oppression, urine strongly albuminous. Lactovegetal *régime* followed by improvement. In consequence of particular strain in moving his home to Lyons, œdema returned, but disappeared after application of leeches to the lumbar region. In December, 1902, the patient worried about his business, and suddenly the amount of urine fell to one pint in the twenty-four hours, while symptoms of uræmic dyspnœa set in. Five leeches were again put to Petit's triangle, and the following day the quantity of urine had more than doubled, but there was still a certain amount of albumin. At the end of a few days the oliguria returned. Digitalis in decreasing quantities again opened the kidneys and dissipated the uræmia. But from that time the attacks returned every ten days.

The patient showed, however, great power of endurance, but in spite of constant changes in the treatment he never could urinate for two consecutive days the amount of liquid he consumed. The urine was always albuminous. It was under these conditions of a struggle for life indefinitely renewed that I commenced (March 15th, 1903) the administration of two pork kidneys macerated for four hours in a pint of salt water. In two days the kidneys were freed, and the patient passed three quarts of urine, or one quart more than he drank. Digitalis, theobromin, or the application of leeches would not have acted better. At the same time the albumin was quickly reduced, and in ten days after the treatment only traces were found, and on April 23rd it had disappeared, to return from time to time in only inappreciable quantities. On May 8th, it had disappeared for good, and examined October 31st last, the urine of twenty-four hours was absolutely free from it. The patient, maintained on the milk and the maceration, passes about as much urine as he imbibes liquid. Every trouble has also disappeared. No more œdema nor bronchitis. As to drugs, he only takes a little strophanthus to sustain the muscular energy. He takes the macerated kidney for periods of ten days, followed each time by a period of rest of five days.

Case II.—Generalised arterio-sclerosis; slight aortitis, interstitial nephritis, attacks of uræmic dyspnœa with pulmonary œdema.

P——, æt. 52. Suddenly seized with an attack of oppression in returning from shooting, followed by persistent headache. Having a syphilitic history, the specific treatment was tried, but without effect. The attacks of dyspnœa were of uræmic character, accompanied by pulmonary œdema and sanguineous sputa; œdema of the legs. The patient had manifestly arrived at the toxic period of Bright's disease. Put to bed and ordered milk diet, the man was given alternately strophanthus and digitalis, while leeches were applied over the kidneys followed by injection of a pint of artificial serum. No great change took place until the patient was given the maceration, and almost immediately the flow of urine became abundant and the albumin ended by disappearing altogether. At present the man enjoys good health, walks about without feeling fatigued or oppressed.

Case III.—The following case furnishes an

(a) Abstract of a Paper read before the Académie de Médecine, Paris. Reported by our French Correspondent.

example of the effect of maceration of the kidney on a patient with albuminuria of cardiac origin. A man, æt. 59, suffering from myocarditis, from grippe and mental strain, albuminuria and renal insufficiency. Digitalis, strophanthus, and theobromin having given but temporary relief, macerated kidney was tried. Almost immediately the patient experienced an improvement; the urine rose to the normal quantity, cyanosis and dyspnœa disappeared, the appetite returned, and the tongue cleared, and finally the albumin was reduced to an infinitesimal quantity.

Case IV.—Alcoholism, interstitial nephritis, big liver with ascites, albuminuria and œdema of the extremities, hypertrophy of the heart and œdema of the lungs.

Butcher, æt. 53, drank daily about five quarts of wine, albuminuria for the last three years, several attacks of uræmia.

Classical treatment (milk, digitalis, theobromin, blood-letting, purgatives, &c.) without effect. The ascites increased and suffocation became more and more imminent. The condition of the patient was very critical. The treatment by maceration was substituted, and the urine, which amounted to only a glass a day, returned to the normal, the visceral congestion and ascites disappeared, the liver became less voluminous, while the albumin persisted, but only in small quantities.

I could multiply such cases, for I have notes of very many, but they would not teach us anything more on the subject, but by the above I think that I have sufficiently established the efficacy of the treatment. Macerated kidney administered to patients suffering from renal insufficiency constitutes one of the most active remedies proposed up to the present. Better than any other, it opens the kidneys annulled by uræmic œdema; it acts rapidly and surely, even where leeches have not been applied to the lumbar region, and its diuretic effects are intense when prolonged sufficiently; it restores the urinary emission to its normal quantity, and maintains it there. The method has also the advantage of surely diminishing the albumin and causes it to disappear for long periods. It consequently gives a chance, by prolonged functional rest, for the restoring of the renal epithelium of glandular order in cases where it is histologically possible. I have never witnessed the slightest accident through its administration, the only inconvenience observed was, in some cases, a slight pruritus, urticaria or sweating.

The *modus operandi* is as follows:—Take one, more frequently two, absolutely fresh pork kidneys, chop them up fine, and then wash them thoroughly in water so as to remove any stagnant urine they might contain. The chopped meat is then pounded up in a mortar with about twelve ounces of salt water (half a teaspoonful of salt), and the whole left to macerate for four hours, and then decanted. The patient will take it in three or four doses in the day. In order to make it more palatable, or rather less repugnant to the patient, I generally have added to it a little warm soup (soup julienne).

The administration of the macerated kidney should not exceed ten consecutive days, after which a rest of five days should be ordered, and the treatment recommenced. It is needless to add that fresh kidneys should be procured every day.

PSEUDO-HYPERTROPHIC PARALYSIS:

ITS HISTORY, ETIOLOGY, SYMPTOMS, AND TREATMENT, WITH AN ILLUSTRATIVE CASE. (*a*)

By JOHN McCAW, M.D.R.U.I.,
Senior Physician, Belfast Hospital for Sick Children.

History.—The recognition of this affection is of comparatively modern date, the first cases being described by Sir Charles Bell in 1830, and by Partridge in 1847. Meryon followed in 1852, with a very accurate account of the disease which he discovered in four boys of one family. From this time onwards numerous observers have published details of cases, among whom may be mentioned Little 1853, Duchenne 1855, Eulenberg and Cohnheim 1865, Charcot 1871, Leyden 1876, and Gowers 1879.

Etiology.—Little is known of the causes of this disease. It is essentially a disease of childhood, and boys are at least four, and perhaps seven, times as frequently affected as girls. Heredity plays an important part in most cases, and it is not unusual for several members of the same family to be attacked; on the other hand, the disease may single out one boy in a numerous family. The affection is transmitted by women who are not themselves the subjects of it. Consanguinity and intemperance in the parents do not seem to have any influence in its production. In one-third of the cases the first symptoms are noticed when the child is making attempts to walk; in another third the child appears healthy and vigorous in all respects until it has reached its fourth, fifth, or sixth year, when some want of power is observed; in three-quarters of the cases the disease is detected before the tenth year, and very rarely no symptoms are seen till puberty.

Symptoms.—Some want of power is the symptom which first attracts attention, and it is common for the parents to notice that the child becomes easily tired when walking. This is soon followed by another early symptom, that is, he falls frequently and shows considerable difficulty in getting on his feet again, or, as Sir William Gowers has tersely put it, "he walks clumsily, falls with ease, and rises with difficulty." On the other hand, the difficulty experienced by the child in getting upstairs is that which first attracts attention. In a typical example of the disease it is usual to find certain muscles hypertrophied, hard, and firm, while others are atrophied. The muscles most commonly hypertrophied are the calf muscles, which may attain a remarkable size, the glutei, the infraspinati, the deltoid, and the triceps. Those most commonly atrophied are the costal and sternal portions of the pectoralis major, the latissimus dorsi, the biceps, the serratus magnus, the flexor muscles of the thigh and the dextensors of the leg. The atrophy of the lower portions of the pectoralis major and the latissimus dorsi causes the posterior axillary fold to disappear to a considerable extent, a condition that is well seen when the arms are extended in front. The face muscles are rarely affected. The position assumed by the patient when standing and when sitting is very characteristic. When standing the trunk is held erect and there is marked lordosis, the upper part of

(*a*) Paper read and Case shown before the Ulster Medical Society, February 18th, 1904.

the trunk being carried so far back that a vertical line from the scapula falls an inch or more behind the sacrum. When sitting the lordosis is replaced by an opposite curve, in which the back becomes convex, both curves being due to weakness of the extensor muscles of the hip. The gait is also very characteristic; it is waddling in character and uncertain, so that small obstacles are overcome with difficulty and the child falls readily. The greatest difficulty is experienced in rising from the floor. If the child is placed on his back on a rug the first movement made towards rising is to roll over on the face; he then gets on his hands and knees; next he manages to get his feet on the ground, and finally by placing first one hand on the thigh just above the knee, and then with the other hand similarly placed, he pushes the trunk up by gradually moving the hands higher and higher up the thighs, or, as Gowers says, "he climbs up himself." The feet tend to assume a position of equinus owing to the contraction of the calf muscles, and at the same time the foot is inverted. The electrical excitability of the muscles is greatly diminished both to the faradic and the galvanic current; and there is never any reaction of degeneration. The superficial reflexes are, as a rule, preserved; the knee-jerks are lost early, or greatly diminished, according to the condition of the quadriceps extensor. Sensation is never affected in any way. The bladder and rectum generally remain unaffected to the last. The progress of the disease is slow; when, however, the power of standing is lost, weakness tends to increase more rapidly, though life after this may be preserved for several years. Death is generally brought about by some acute disease, and frequently by a pulmonary affection such as broncho-pneumonia or phthisis. The mental condition of the subjects of this disease has been variously stated. Gowers says the mental development is generally beyond that of other children of the same age, and that mental defect is a pure complication. Ashby thinks that some degree of mental deficiency is a not uncommon association.

Pathology.—No lesion can be found either in the spinal cord, the anterior or posterior roots, the peripheral nerves, or in either the finer motor or sensory fibres passing to the muscles. The muscles alone show any pathological change, although Babes has shown that changes exist in the motor end plates. The muscles to the naked eye appear pale, and resemble a mass of fat, or they have a brown, firm, and hard appearance. On section of a muscle it is seen that there is a great increase of the connective tissue, not only between muscular bundles, but also between the individual muscular fibres, so that the fibres themselves become surrounded by a ring of connective tissue. Some fibres are atrophied, while others may be hypertrophied, and in between the fibres fat becomes deposited. No matter to what degree the fibres become atrophied they still retain their transverse striation. A few of the fibres may show fatty degeneration and some may be vacuolated. A very striking feature in some of the muscles is the number of muscle-spindles that can be seen in cross section of a muscle in a given area.

Treatment.—Drugs are powerless to effect any amelioration of this disease or even to stay its progress. The most important items in the care of such cases are to keep the little patient warm, and to shield him from the risks of catching cold or developing any lung trouble. Something may be done in the way of massage and faradising the affected muscles, and he should be encouraged to walk as much as he is able, and as long as it is possible. Gymnastic exercises are indicated and should be used perseveringly. The general health and strength should be maintained at the highest standard, and to this end the most nourishing food and cod-liver oil are desirable. Such general tonics as iron, arsenic, phosphorus, and strychnine may be given.

Illustrative Case.—The patient shown to-day is W. H——, who was admitted to the Queen Street Hospital for Sick Children under my care on February 3rd, 1904.

History.—He is 9½ years of age, and is the fifth child of a family of eight, which consists of five boys and three girls. All the other children are strong and healthy, and in particular his four brothers have never shown any sign or symptom of being affected in a similar way. The parents say that he was late in attempting to walk when compared with the other children, and that he was easily knocked down and had considerable difficulty in getting up again. He was sent to school when four years old, and at this period was able to walk fairly well, but his power of walking became steadily worse, so that for the past three years he has been unable to walk the distance. His speech is, and always has been, defective, and he was slow to learn and very irritable in temper. He is mentally deficient and at times impulsive and violent. The calf muscles are enormous, measuring 11½ in. in circumference; the glutei and infraspinati are very prominent, while the pectoralis major and latissimus dorsi are greatly atrophied. The forearm muscles are hypertrophied and the upper arm ones atrophied. His parents are strong and healthy, and no history of any similar affection could be obtained as having occurred in either of their families. The patient is, therefore, an example of pseudo-hypertrophic paralysis associated with mental deficiency, and the history of the case leaves little room to doubt that it is congenital.

With the kind co-operation of Mr. Robert Campbell and Dr. Beatty, a small portion of the left calf muscle has been excised and mounted, from which it will be seen that the fibrous tissue is increased and the muscle bundles atrophied.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXXV.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

THE LONDON OPEN-AIR SANATORIUM.

Pinewood, the London Open-air Sanatorium, is situated at Nine Mile Ride, Wokingham. It owes its existence to the generosity of Messrs. Wernher, Beit, and Co., who contributed £40,000 towards its establishment. It was intended to meet the needs of consumptives belonging to the less wealthy middle-class, and be self-supporting.

The sanatorium is delightfully situated at an elevation of 252 feet amidst pine woods, on the confines of Old Windsor Forest. The adjacent country is studded with pines or consists of heather-land. The estate is eighty-two acres in extent, and the sanatorium stands in a clearing well open to the south. The soil is sandy. The surrounding pine woods afford much shelter and offer opportunities for varied walks, and are peculiarly suited to serve as pleasant resting-places. Several

well-designed roomy shelters have been erected near the main building. Although new houses are quickly arising in the neighbourhood, the sanatorium is secluded, and, having fairly extensive grounds, is not likely to suffer serious detriment, at least for some years to come.

The most serious drawback, perhaps, is the somewhat isolated position, which renders access difficult. The sanatorium is about two miles from Wellington College Station on the South-Eastern Railway, three and a half miles from Bracknell on the London and South-Western Railway, and eleven miles from Reading. The quickest approach is by taking the Great Western express to Reading, and thence by a stopping train on the South-Eastern Railway to Wellington College, where a carriage is always to be obtained at the adjacent hotel.

The sanatorium has been built in accordance with modern conceptions, but is wanting in several important respects, such, for instance, as end or outside staircases, and there is very conspicuous lack of privacy in the resident medical officers' quarters. Many improvements, however, have been made since the opening of the institution upwards of three years ago, and no doubt as funds are forthcoming other extensions and modifications will be undertaken.

The building consists of a central administrative block with separate bedroom blocks on either side. The medical officers' rooms are small and not sufficiently separated from the patients' quarters, and the main corridor runs through the central block.

The patients' blocks consist of ground and first floors. Each patient has a separate room. The rooms face approximately south. There are no balconies and no verandahs to these parts of the building, but at either end there are excellently designed open-air galleries, which allow of free exposure, and yet provide for shelter from winds. These galleries or open balconies are so constructed as to allow of the north aspect being available during hot summer weather.

Each bedroom, although small, is comfortable, simply furnished, well lighted, but the windows might with advantage have been brought nearer the floor. Each bed is of good construction, and a cane couch is also available and would seem to serve as an encouragement for the patient to rest in his or her own room during the day, a procedure which many would not approve. Each room is supplied with a fire-grate, but radiators have been added. The sanitary offices are well placed, and the appliances thoroughly efficient.

The dining-room, which stands north of the administrative block, is a particularly well designed, excellently lit and airy structure. A nurses' dining-room is adjacent, and the kitchen near by is well fitted with all modern appliances. There is a good laundry, and the boiler-room, electric plant, stables, and other outbuildings are conveniently placed and well equipped. The accommodation for nurses is inadequate, and better arrangements generally should be made for the resident staff. The sanatorium is lighted throughout by electric light. Sewage is dealt with in a septic tank. The water supply is good, and arrangements have been made to provide against the danger of fire. There is accommodation for sixty-four cases, an equal number of each sex. Many of the cases are "bed" patients.

The resident medical officers are Drs. C. C. Chidell and Roland Stevenson. Dr. Hector Mackenzie and Dr. Alfred Hellier are the visiting physicians.

Treatment is conducted in strict accordance with modern hygienic conceptions. We lunched with the patients and found the character of the food and manner of serving thoroughly good. The general daily routine is well defined. The "directions" are as follows:—

"7.30 to 8.30 a.m.: Rub down or bath as ordered. Bath should be nearly cold. Don't get out of breath by rubbing with towel. Please do not leave your room till you have seen the doctor. 8.30 a.m.: Breakfast. 9.30 a.m.: Morning walk begins (distance and pace regulated for each patient). If you are up to breakfast you must be out by 9.30. 11.55 to 12.55: Rest on couch in bedroom. Go to your room at 11.45 to take your temperature so as to ensure a full hour's rest. (Reading or writing allowed, but not hard study or business correspondence.) 1 p.m.: Dinner. 2 to 3 p.m.: Rest sitting or lying, out of doors or in a shelter. A short siesta is advisable, but talking and sedentary games are allowed. An exception to this rule is made on Sunday. 4 p.m.: Afternoon tea. 4.30 p.m.: Afternoon walk (distance one-half or one-third of morning walk). If the weather is not too hot this walk may be taken between 3 and 4. 5.55 to 6.55 p.m.: Rest on couch; go to your room at 5.45. 7 p.m.: Supper, after which a short stroll may be taken, or the time spent in dining hall, library, or, better still, in a shelter. 9.30 p.m. at latest: Bed time.

"A bath (not too hot) may be taken once a week. 10.30 at latest: All lights out.

"Temperature is taken four times daily: (1) On awaking, before rising (stop in bed if temperature is above 98·6° F., or 37·0° C.). (2 and 3) Immediately after morning and afternoon walks. (4) After getting into bed at night."

The following are among the "instructions" given to patients when leaving for home:—

"*Disposal of Sputum.*—If there is a water-closet, the simplest way is to empty the sputum direct from the pocket-flask into the pan. In the absence of a water-closet, the sputum should be poured into a "poke" (*i.e.*, a conical bag) made of three or four layers of newspaper and containing sawdust. The sputum must be well mixed with a little stick, which should then be burnt with the poke and its contents. Every mug used for spitting should be lined with butter-paper, and it is well to have a little carbolic acid solution (one part pure carbolic acid to nineteen parts of water) at the bottom of the paper. The butter-paper and its contents may be thrown into the water-closet pan or burnt with sawdust as above. If there are neither drains nor fires (only gas cooking stoves) the sputum should be buried.

"*Cleansing of Flasks and Mugs.*—After emptying the flask, pour into it a teaspoonful of the above carbolic acid solution. At least once a week the flask should be disinfected by immersion with open ends in the same solution over night; in the morning the carbolic acid is thrown into the pan of the water-closet, and the flask is rinsed through with hot water, to which common washing soda (about two teaspoonfuls to a pint of water) may be added. Mugs should be cleansed daily after use with carbolic acid solution, followed by rinsing with hot water or hot soda solution.

"*Disinfection of Handkerchiefs.*—Cheap Japanese paper or calico handkerchiefs may be burnt after use. This method is the best, and is essential when the handkerchief has been especially exposed to infection by coughing or still more by spitting into it. If better handkerchiefs are used they should be boiled for half an hour in a special saucepan, or any of the following disinfectants may be used to soak the handkerchiefs for twelve hours before washing in the ordinary way:—Carbolic acid, 1 in 20; chloros, 1 in 200; formalin, 1 in 20.

"It is desirable that the above precautions should be taken as long as there is any expectoration."

It was hoped that the fees at Pinewood would be kept low in order to meet the needs of the cases for which it was originally intended, but already the sanatorium is in active competition with other institutions for comparatively well-to-do patients, and the fees are £3 3s. a week. The sanatorium is, however, an excellent one, pleasantly situated, skilfully controlled, and as far as we can ascertain accomplishing much good work.

Continental Health Resorts.

[FROM OUR SPECIAL CORRESPONDENT.]

BEX-LES-BAINS (SWITZERLAND).

BEX-LES-BAINS is situated in the Rhone Valley

(about twelve miles from Lake Leman), at an altitude of 1,430 feet, on the line of the Jura-Simplon railroad running from Geneva and Lausanne to Zermatt and Brique. From Martigny, twelve miles above Bex on this line, picturesque carriage roads ascend to Chamounix and to the great St. Bernard. At Loèche-Souste station, thirty miles from Martigny, are carriage connections with Loèche-les-Bains, at the foot of the celebrated Gemmi Pass on to the Bernese Oberland. Twelve miles further up the Rhone valley, at Viège is the junction with the Viège-Zermatt railway. Five miles above Viège from the terminus station at Brique, diligences run to the world-famous Glacier du Rhone, and thence by the Grimsel Pass to the Interlaken Valley, or by the Furka—finest of Swiss passes—to the St. Gothard railways, connecting with the Lucerne Lakes, the Righi, Zurich, Engadine, Tyrol, and Italian lakes.

Bex-les-Bains is thus admirably located in the leading tourist routes. It is, likewise, an excellent centre for short excursions. The ancient towns of St. Maurice and Sion, and the well-known glacier, cascade and gorge of Trient, are within easy distances; as are also Aigle-les-Bains, Corbeyrier, Leysin, Diablerets and the Ormonts; and the Castle of Chillon, Montreux, Caux, and the Rochers-de-Naye. Across the river are the Val d'Illiez and Champéry with their fine forests, rich and varied flora; and bifurcated feminine attire of antique descent and design, yet *à la Bloomer!*

From Bex station, a tramway, passing through the town and near the salt mines, ascends to the attractive summer-homes of Gryon, Arveyres, Chesières, and Villars-sur-Ollon.

The town of Bex, built on a plateau in a vale of the Vaudois Alps, is well sheltered on the north by the Montet hill and woods, and easterly by a chain uniting the Morcles, Muveran and Diablerets ranges. Southerly and westerly are the superb heights of the Dents de Morcles and du Midi, and the surmounting ranges, of hills and peaks stretching away in the distance from Valais into Haute-Savoie. Half a mile from the town and nearly 200 feet above it, is an undulating large park, with umbrageous avenues, pleasant shady paths, small lakes, grottoes, and tennis-lawns, in which stand the Saline Thermal establishments and the Grand Hôtel des Salines, with their annexes. Here, in close vicinity to fine forests and mountains, the air is very pure and salubrious, the climate mild and sedative, and there is a remarkable freedom from winds, saving occasionally the *foehn*, the warm south wind of Alpine valleys. Although so sheltered, even in hot summer days only the mid-day hours are sultry, refreshing mountain breezes rendering the evenings and mornings cool and agreeable. The atmospheric calm is delicious and beneficial to the delicate guests at Bex, as they can remain long in the open air.

Owing to its sunny and sheltered position the bathing "season" here commences earlier and continues later (April 1st to October 31st) than is usual at Continental spas. For British, Americans and Colonials the preferable months are in spring and autumn particularly spring, when the glades and terraces of the wooded slopes are most attractive for the brilliant greens and exquisite colourings of their sub-Alpine flora. From the Jura-Simplon railroad station an electric tramway runs through the town to the Salines Hotel and Baths, and thence on to the salt works at Bevieux. The mines, *au Bouillet*, lie N.E. an hour's walk further, amidst rocks and erratic blocks. The galleries, some at 600 feet depth and one nearly a mile in length, are cut into the subterranean salt beds from which the salt is washed out, the brine being conveyed by pipes to the works for condensation in pans. A cemented covered brick canal connects the works with the Baths at the Grand Hôtel des Salines. To all the other hotels at Bex, the brine is carried in great barrels.

By the analyses of Professor Brunner, of Lausanne, the Bex brine contains:—

Chlorides de sodium	..	274·413 grammes
,, calcium ..	..	22·876 ,,
,, magnesium	..	9·063 ,,
,, potassium	..	1·987 ,,
,, lithium ..	..	0·104 ,,
Bromine et iodine magnesium	.. .. ..	0·101 ,,

These analyses show that the saline waters of Bex-les-Bains rank very high among the strongest salt waters of Europe. And for the efficient applications of the Bex waters the bath establishment possesses the most approved and latest hydro-therapeutic apparatus.

The Grand Hôtel des Salines here has also the most modern arrangements for the comfort of its visitors, added to the very great advantage of having on each floor direct communication with the baths.

In his article "The Salt Baths of Bex" (see MEDICAL PRESS AND CIRCULAR, 1902), Dr. Eugène de la Harpe, the resident physician at Bex Salines during the season, says, "Bex can be advised in all cases where salt medication is useful; lymphatism, scrofula, rickets (the combination of baths and climate being especially good), chronic diseases of the female generative organs, exudates, and remains of acute processes in the pelvis; also such remnants in the abdomen after perityphlitis, appendicitis, peritonitis, or in the chest after pleurisy, chronic rheumatism, rheumatoid arthritis, &c. Anæmic and neurasthenic patients come to Bex for the hydrotherapic treatment."

At the Bex Salines is likewise a cold sulphur spring used for drinking, inhalation, gargling, &c. The fango, Nauheim, and rasin cure treatments are also administered here. The resident physician speaks English.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

CLINICAL EVENING HELD FRIDAY, FEBRUARY 26TH, 1904.

DR. FREDERICK TAYLOR, President, in the Chair.

MR. F. J. STEWARD exhibited a case of movable knee-joint three and a half years after operation for extensive tuberculous disease, in a girl, æt. 5. Primary healing was obtained, and the limb was in a plaster of Paris splint for two years.

Dr. H. BATTY SHAW showed a mother and infant daughter affected with a congenital deformity of hands and feet. The mother was æt. 20. When the hands were at rest the digits were held somewhat flexed, the index fingers being curved laterally, and appearing to be separated more than usual from the remaining digits. The inter-osseous spaces were wasted. Movements of flexion and extension were satisfactorily performed, but abduction and adduction of the digits were greatly reduced. There was also complete paralysis of the frontalis muscle. The child, æt. 2 months, presented a similar deformity of the hands and feet. Radiograms of the mother's hand showed that beyond the slender character of the fourth metacarpal bones and the prominence at the base of the third, the bones were normal.

Dr. BERTRAM ABRAHAMS showed a sporadic case of Friedreich's disease in a boy, æt. 13, the third of eight children, of whom the others were perfectly healthy. The illness began five years ago, and the ataxy had rapidly increased during the past three years. There was slight lateral nystagmus. The pupils were widely dilated, but reacted briskly to light and accommodation. Romberg's sign was well marked. The speech was nasal, slow, slurred, and monotonous. There was considerable ataxy of the hands. Both knee-jerks were lost, and the plantar reflexes were of the extensor type. Pes cavus was present on both sides.

and there was distinct dorso-lumbar scoliosis. Treatment by Fraenkel's method was proposed.

Dr. J. PORTER PARKINSON exhibited an unusual case of morbus cordis in a girl, æt. 9, who, since the age of seven, had had repeated attacks of acute rheumatism. The cardiac impulse was best marked in the fourth interspace just inside the nipple, and on admission to hospital she had epigastric pulsation and extension of the cardiac dulness to the right of the sternum. At the apex were double mitral murmurs, and at the base were systolic and diastolic murmurs, heard best at the second left interspace. There was no abnormal arterial pulsation, and the pulse was 70, small, regular, and compressible.

Dr. H. BATTY SHAW thought that the proof that the case was one of aortic regurgitation was very incomplete. He could not help feeling that the condition was due to high tension in the pulmonary artery, which gave rise to the murmur, which had been described by Dr. Graham Steele.

Dr. ALEXANDER MORISON considered that the absence of a thrill negatived the diagnosis of pulmonary endocarditis, and he was inclined to agree with Dr. Shaw that the condition was more functional in character.

Dr. W. HALE-WHITE said that the presence of the systolic murmur rather indicated the existence of some endocarditis of the pulmonary valves.

THE PRESIDENT observed that the murmur in question was heard very distinctly high up on the left side of the sternum. He would hesitate to pass an opinion without further examination.

Dr. PARKINSON, in replying, commented upon the great rarity of pulmonary endocarditis, and considered that the condition was probably due to dilatation of the orifice from incompetence of a normal valve.

Dr. W. G. STONE showed a lad, æt. 8, with enlargement of the bones of the cranium, jaw, and thorax. The evidence was very strong that the lesions were syphilitic.

Mr. CHARLES R. KEYSER exhibited a male infant, æt. 15 months, the subject of achondroplasia with spinal curvature. The head was large, and the fontanelles widely open. The nasal bridge was depressed. There was marked disproportion between the length of the body and that of the limbs, the bones of which were only slightly curved. The fingers showed the typical appearance of the disease, the index and middle fingers curving to the radial and the ring and little fingers to the ulnar side. There was no lordosis. nor was bony tenderness marked. There was a prominent antero-posterior curve in the dorso-lumbar region. The lower ribs were everted and the abdomen was prominent. The father was only 4 ft. 8 in. in height.

The PRESIDENT inquired if anything unusual was noticed about the child at birth.

Mr. KEYSER replied that the shortness of the limbs had been observed. He considered that there were several features in the case, especially the spinal curvature, which resembled those met with in ordinary rickets.

Mr. EDRED M. CORNER showed a case of pyopneumothorax due to phthisis, in a man, æt. 32, for the cure of which operations on the principle of Estländer's (thoracoplasty) were performed. Healing had taken place with the formation of an aerial fistula.

Mr. W. G. SPENCER referred to a case under his own care in which a bronchial fistula had resulted which had remained stationary for three years.

Dr. WILLIAM HUNTER and Mr. STEPHEN PAGET showed a lad, æt. 17, the subject of progressive myositis ossificans. The disease began at the age of four, and since then had steadily advanced. Ten years ago he was seen by Sir James Paget, and reported by Mr. Stephen Paget at the time. There was a definite family history of rheumatic fever. The muscles now chiefly affected were the pectoral, the latissimus dorsi, and the teres muscles, all of which were firm, rigid, and contracted, so that both arms were tied to the chest at the shoulder-blade. There was a deposit of bony growth around the left angle of the scapula. A considerable degree of scoliosis of the spine was present, with great wasting of the muscles of the back. Radiograms exhibited well-marked shadows at the attachment of the pectoralis major to the humerus.

Dr. C. GOULD MAY showed a female child, æt. 6, with multiple exostoses on the bones of the limbs. There was no history of rheumatism, nor was there any pain.

Mr. WILLIAM H. BATTLE asked if there was a family history of a similar condition, and if any effect had been produced upon the growth of the bones.

Dr. MAY replied.

Mr. DONALD ARMOUR showed a man, æt. 20, who had a cyst arising in connection with the organ of Giraldès, the origin of which was unknown.

Mr. T. HORROCKS OPENSHAW exhibited a female patient, æt. 31, in whom he treated a contracture of the right hip and knee by elastic traction. The condition had lasted for fifteen years as a result of infantile paralysis. In July, 1903, she was placed in a Hessing's apparatus with elastic traction. Considerable improvement had resulted, and confidence in walking was increasing.

Mr. WILLIAM H. BATTLE showed a woman, æt. 55, the subject of a large femoral hernia on the right side. The hernia had been present for seventeen years; it was as wide as the patient's thigh, and extended downwards as far as the upper margin of the patella. It contained intestine, and the skin over it was somewhat eczematous in parts. He proposed to operate upon it when the general condition had improved.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

MEETING HELD FRIDAY, FEBRUARY 19TH, 1904.

H. C. EARL, M.D., President, in the Chair.

POINTS IN THE PATHOLOGY OF SENILE HYPERTROPHY OF THE PROSTATE.

MR. TOBIN remarked that whereas when he read a paper on this subject some ten years ago all the specimens were derived from the post-mortem room, now the operating theatres provide the material for discussion. This material usually came in two shapes: one, a smooth-faced, easily enucleated adenoma, often of large size; the other, commonly a smaller mass with a rough surface and looking like muscular tissue to the naked eye, and containing in its centre the prostatic urethra, torn portions of which, or of the membranous urethra, hung out at one end. Specimens presenting such points of identification had been looked upon as showing an hypertrophied prostate removed in its entirety. Anyhow, such, he said, was his opinion till reading what he called an epoch-marking paper on this subject by Mr. Wallace in the *British Medical Journal*, January 30th, 1904. He then showed some recently removed specimens, which he maintained both microscopically and macroscopically fully bore out Mr. Wallace's contention. Among them was one which he described as follows:—"When my finger, shelling out this large adenoid, had reached its posterior surface and was still between the layers of the surgical capsule, I opened into a sac in which these calculi were lying free. They are, as you see, a hundred or so in number, varying in size from a grain of snipe-shot to a swan-shot, smooth and round except one, which is the size and shape of a bean. The received opinion is that calculi such as these develop primarily in the glandular crypts of the prostate, and that their presence in one pocket is due to an amalgamation of crypts. If this is so the opening up of these crypts while my finger was traversing the capsule points very clearly to the composition of that envelope."

Dr. DARGAN stated that the sections shown were made from the very outermost laminated layers of what seemed to be merely a fibrous envelope to the growth. They showed here and there atrophic glandular spaces, lined in many cases by cubical cells, but greatly compressed, and evidently undergoing involution. The

presumption is, that these are derived from greatly compressed prostatic tissue.

The SECRETARY stated that he was quite certain that a few, at least, of the cases of senile enlargements of the prostate were true hypertrophies.

The PRESIDENT said that he agreed that senile enlargement of the prostate was of a glandular nature. He had not always been able to find glandular or muscular tissue in the fragment of tissue adhering to the prostates removed by operation. In a number of examinations he had only once found a small myoma. He mentioned a case of prostatic obstruction due to a cyst in the left lobe.

Mr. TOBIN, in replying to the remarks of the President stating that most of the cases that he had examined were either true hypertrophies of the prostate or adenomata in the prostate, but not converting it into a capsule, asked: What, then, of the capsule that certainly exists in all cases of senile hypertrophy? He had never failed to shell out the offending mass in such cases, but he had always utterly failed to shell out a tuberculous prostate in the operating theatre or a normal prostate in the dissecting room.

ENDOTHELIOMA.

Mr. L. G. GUNN showed a case of endothelioma of the peritoneum occurring in a man, æt. 28, with extensive secondary growths in lung, liver, and bronchial glands.

Mr. BENNETT asked whether the primary growth had been found, as all the growths shown seemed to be secondary.

Mr. GUNN replied that the most careful search for a primary lesion had failed, and, acting on the presumption that the growth had originated from the peritoneum itself, it had been labelled an endothelioma.

IMPLANTATION (OVARIAN) TUMOURS.

Mr. L. G. GUNN showed a femoral hernia, in which a distinct secondary ovarian growth had occurred. The ovarian tumour had been removed nineteen years before. The hernia had enlarged for a few months before.

Dr. NEVILLE exhibited a transplantation cystic tumour from the scar of an old (five years) ovariotomy. The tumour shown was about the size of an ordinary fist, and consisted of a congeries of small cysts, approximating twenty in number, varying in size from that of a pea to that of a large walnut. Microscopic examination showed a marked resemblance between the peculiar epithelium lining each cyst, and that constantly found in Graafian follicles, the so-called membrana granulosa, specimens of which were shown. It was, of course, impossible to rely very certainly upon such a resemblance in the absence of any other explanation.

The SECRETARY found some difficulty, owing to the amount of calcification, as shown by the sections under the microscope, in believing that the transplanted ovarian papilloma had recently been actively growing, and wished to know Mr. Gunn's opinion on that point.

Mr. GUNN replied that, in his opinion, most of the enlargement was due to the growth within the omentum, and not from any fresh omentum coming down into the sac.

DOUBLE-SIDED DERMOID CYSTS.

Dr. NEVILLE exhibited tumours which were removed from a patient, æt. 25, in the Rotunda Hospital, by the Master, Dr. E. Tweedy, and remarkable for the marked differences of the two tumours. One, the smaller one, was an ordinary dermoid, in size about that of a fœtal head, and consisting mainly of two cysts, a considerable portion of the inner surface of which was lined by skin, covered with white hairs. But the larger tumour, rounded, smooth, and measuring eleven inches by eight inches, was essentially a solid tumour, presenting on section a very peculiarly variegated surface, with occasional small cysts, few of which, however, were larger than a walnut. Some of these quite small cysts were partially lined by skin and hair. The solidity and malignant appearance of the growth had at first suggested that it might prove to be a teratoma on microscopical examination. This showed, however, the general appearance of a cystic adenoma, the epithelium lining of the cysts being mostly composed of goblet cells. Sections of the skin cysts had not yet been made, but Dr. Neville was convinced that the tumour really consisted of a very unusual and very solid form of dermoid cystadenoma.

TERATOMA.

The PRESIDENT showed a teratoid tumour of the ovary. It was taken from a young woman, who died with abdominal symptoms some months after its removal. Sections taken from different parts of the tumour showed small cavities lined by epidermis, and having hairs and sebaceous glands in their walls. Other cavities were found to be lined with a columnar epithelium, and glands resembling Lieberkühn's crypts opened into them. Bone, cartilage, masses of pigmented cells, adipose tissue, and tissue resembling that of the central nervous system were also found, as well as groups of ganglionic nerve cells.

CALCIFIED FIBRO-MYOMA.

Dr. NEVILLE also exhibited a completely calcified fibro-myoma of the uterus, removed, with other non-calcified fibro-myomata, by Dr. L. Kidd, of Enniskillen. Tumours so completely calcified were certainly rare in connection with hospital practice, though not uncommonly found in connection with anatomical schools.

Mr. BENNETT related a case which he saw several years ago, in which a calcified myoma ulcerated into the bladder, and was diagnosed as stone. In the attempt to remove it the patient died. The true nature of the mass was only discovered years afterwards.

THE HARVEIAN SOCIETY OF LONDON.

MEETING HELD FEBRUARY 11TH, 1904.

Mr. E. W. ROUGHTON read a paper on a case of

INTESTINAL OBSTRUCTION WITH GANGRENE OF THE CÆCUM.

The case was one of obstruction needing immediate treatment; an umbilical hernia existed, but was soft, painless, and gave an impulse; it was, therefore, not the source of the symptoms. A median incision was made, and an enormously distended cæcum was seen. During manipulation the cæcum burst and flooded the operation area with fæces, but the peritoneum was protected by gauze packing. Paul's tube tied in. Later Mr. Legg removed a cancerous growth from the sigmoid. The patient made a good recovery.

Mr. LEGG described the method of removal of the growth in the sigmoid flexure, which included four inches of the gut and a wedge of the mesentery. End-to-end suture employed, the first layer through all the coats, and the second through sero-muscular coats, parietal wound closed. The colotomy wound was plugged with a sponge, and the skin sutured closely over it during the operation. Patient did well.

Mr. PATON discussed two cases of partial hernia he had recently treated, in one of which, although a small portion of the gut was tightly constricted and was sloughing through, symptoms were purely local; in another case the condition of the hernia did not indicate the existence of local symptoms, which rather resembled perforated gastric ulcer, thus showing how sloughing of the gut often gives rise to anomalous symptoms.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD WENESDAY, FEBRUARY 24TH, 1904.

J. COTTER, M.D., F.R.C.S.I., President, in the Chair.

DR. H. R. TOWNSEND read notes of five cases of appendicitis operated on in the acute stage. In four cases recovery followed, while in one case, owing to the mildness of the symptoms, surgical aid was not requisitioned at an early stage, and when the operation was performed the appendix and surrounding portions of intestine were found in a gangrenous condition, and the patient died five days later. In his opinion, as soon as a diagnosis of appendicitis was made, an

operation should be at once advised, as there were no trustworthy means of foretelling from day to day what course the case would take.

Dr. T. GELSTON ATKINS read notes of a series of cases of cholecystotomy, choledochotomy and cholecystectomy, and maintained that with the improved methods now adopted, gall-stones should be always treated by surgical means.

Dr. P. J. O'BRIEN read notes of a case of puerperal eclampsia complicated by acute sepsis, and of a similar case of eclampsia complicated by acute mania. The patient in the first case recovered after a very severe illness. In the second case the patient had to be removed to the asylum, but was at present, after two months, practically well, and was about to be discharged.

Dr. D. MORRISSY read notes of three cases of tetanus treated by anti-tetanic serum. In two of the cases the patients recovered. In the third case the patient, a woman, æt. 50, recovered completely from the tetanus in a week, but sixteen days after admission to hospital was attacked by broncho-pneumonia, which proved fatal nine days later.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 28th, 1904.

TREATMENT OF CHRONIC RHEUMATISM.

ACCORDING to Dr. Huchard, the medical treatment of chronic rheumatism consists essentially in iodide of potassium and arsenic. If the patient seems weak, arsenic will be given for three weeks in the form of Fowler's solution (5 drops twice daily), or of solution of arseniate of soda: arseniate of soda, 1 grain; water, 10 ounces (a tablespoonful before lunch and dinner).

If, on the contrary, the patient is vigorous, preference will be given to iodide of potassium (6 grains daily), and continued three weeks or a month.

However, if the rheumatism be of arthritic character, iodide will be of little use; it should be replaced by tincture of iodine, 5 drops three times a day in a glass of water, gradually increased by 1 drop daily to 10 or 15 drops each time, and continued a month, after which it should be suspended for ten days, and then recommenced. The treatment might be continued for months if the patient's stomach can support it. If an excess of uric acid be secreted, piperazine might be given:—

Piperazine, 1 drachm.
Water, 10 oz.

A tablespoonful twice a day for five days, and suspended five days, and so on for six weeks.

Colchicum was recommended by different authors, but in the hands of Dr. Huchard it gives no good result except when the rheumatism is of a gouty nature. Salicylate of soda might be tried in acute attacks of chronic rheumatism, but it acts less effectively than in the inflammatory form. In any case it is superior to antipyrin, aspirin, salophene, &c.

As regards external remedies, igni-puncture and blisters are employed successfully in chronic rheumatism, and tincture of iodine is of current application. An ointment which is frequently found very serviceable is that composed of salicylic acid:—

Salicylic acid,
Ess. of turpentine,
Lanoline, aa 10 drachms.

In cases of painful chronic rheumatism. M. Dieulafoy recommends a very simple application: poultices of bread crumb moistened with spirits of camphor and coated with the following mixture:—

Camphor, 2 drachms.
Extract of opium, 1 drachm.
Alcohol, q.s.

The preparation of the poultices is a little intricate. Four pounds of bread crumb are steeped in water for about five minutes; it is then pressed in linen and placed in a sand bath for three hours. At this point the bread forms a dry paste, and is softened gradually by the addition of spirits of camphor. The paste is then kneaded and spread upon a piece of linen, while the above mixture is spread over the whole surface. Thus prepared, the poultice is placed on the articulation and covered with a sheet of gutta-percha, and held in place by a flannel bandage; the application remains in place from eight to ten days.

Of the other methods generally recommended for chronic rheumatism, M. Huchard mentions massage, electricity, warm baths, hot air baths, turpentine vapour baths. Massage renders great service in the treatment of rheumatism deformans by suppressing pain and avoiding ankylosis. The ointment employed in the massage would be as follows:—

Tincture of nux vomica, 1 drachm.
Spirit of lavender, 1 drachm.
Vaseline, 6 drachms.
Lanoline, 6 drachms.

The warm baths are given every two days for ten or twenty minutes, and the temperature of the water is gradually raised while the patient is in the bath to the highest degree possible. Different substances might be added to the bath, but more especially essence of turpentine (black soap emulsion, essence of turpentine, of each 4 ounces). The hot sand bath gives much relief. The sand, heated in an oven, is poured into a tub and allowed to cool to 110°, the limb, bandaged, is plunged into the tub for twenty to twenty-five minutes. Bergeret recommended enveloping the joint in carded wool and placing on it three or four pounds of hot sand. He alleged that this treatment applied to hydarthrosis of the knee caused the effusion to disappear in a very few days.

Turpentine vapour baths are frequently employed. M. A. Robin uses them freely at the Hôpital de la Pitie. The baths are administered every two days, and last from ten minutes to a quarter of an hour; the vapour jet is received in a sort of tent in which the body of the patient is imprisoned up to the neck.

The hydropathic establishments for the treatment of chronic rheumatism are very numerous in France, but they should not be recommended indiscriminately. La Bourbonne (Haute-Marne) suits inveterate and exhausted rheumatic patients; Luxeuil (Haute-Saone) neuropaths; Neris (Allier) neuro-arthritics; Aix (Savoie) torpid rheumatism, peri-arthritis; the mud baths (sulphur) of Saint-Amand (Nord) succeed very well in all forms of chronic rheumatism.

In conclusion, M. Huchard says that chronic rheumatism is much more amenable to treatment than the arthritic form. This latter is not as yet very well understood as to its real cause, its nature being very complex, but the treatment already indicated—large doses, internally, of tincture of iodine, massage, and the hot sand bath—gave the least unfavourable results.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 28th, 1904.

AT the Free Society of Surgeons, Hr. Karewski gave an address on

HERNIA OF THE BLADDER.

As to the origin of the condition, either a prævesical fatty tumour dragged the bladder forward or grew in the bladder wall and weakened it. The important

points in connection with it were the size of the bladder, peritoneal adhesions, the size of the rupture and of the opening. He had seen five cases. Two of them could be verified cystoscopically; one was recognised as such at the operation, one only by a fistula remaining after operation. On a ligature being applied, a portion of the bladder wall was included in it, and the fistula resulted. Four were extra-peritoneal and one intra-peritoneal. All were characterised by a large development of prævesical fat. He had also made twenty-three observations on seven bodies. The result of his investigations was to determine that with a full bladder a connection existed between the hernial opening and the bladder wall, the more intimate, the larger the opening was; with increase in growth, therefore, the danger increased of including the bladder wall in the ligature. There was no diverticulum, however. If the bladder wall was injured on such an occasion, it was not a proof that an actual hernia existed. A further result of his investigation was to show that there was an intimate connection between prævesical præperitoneal fat and the bladder wall.

Hr. Israel spoke on

Artificial Substitutes for the Ureters.

He spoke of the importance that congenital hindrances had to the flow in hydronephroses. The disease first became manifest in the course of years either through increase of tension and accompanying colic, or through infection of the contents. Thus a boy, æt. 13, suffered for two years from left-sided renal colic, in whom a distinct sac could be felt during the attack, which became smaller, however, when the attack subsided. As the attacks became more frequent an operation was performed in December, 1902. A sort of blind sac-bulging of the pelvis of the kidney was found below where the ureter was given off. The ureter was perfectly permeable. The kidney was deeply placed, and its fixation at a higher level was not practicable. The position of the kidney was plainly congenital. Experimentally he first of all sutured the ureter with the lower part of the dilated pelvis of the kidney, but twenty-four hours later the colic returned and a drain had to be inserted. For ten days the urine remained clear; then it became cloudy, and a metastatic infection suddenly developed in a hydronephrosis of the right side that had up to then been latent. A tumour was soon palpable, and anuria set in, the left kidney also ceasing to secrete. The sac of the right side had now to be emptied and a drain inserted. The excretion of urine then came on again, but there were no means of conducting the urine into the bladder. The speaker at last determined to make a suprapubic vesical fistula and to join the kidney and the bladder by means of a tube running externally, and provided with a flap in order to prevent any back flow. The apparatus had now been working for eight months and had acted well.

He had operated four times for hydronephrosis of congenital origin. He then described a

Process for Exposing the Posterior Surface of the Liver.

An officer, æt. 41, had suffered for five months from pain in the right loin, which was worse on coughing, sneezing, or pressure on the lumbar region. More recently there had been fever. In spite of an enormously increased appetite there was extreme weakness. Urine normal, the right kidney could be felt; the liver was not enlarged. The symptoms pointed distinctly to some mischief in the right subphrenic space. First the adrenal gland was thought of, but against any disease of this was the fact that there was no disturbance of digestion. Only the liver remained. Afterwards the patient spoke of syphilis in earlier life, and the most probable assumption now was of a breaking down gumma in the liver. It was decided to explore. He made a transverse incision on the lower border of the twelfth rib and exposed the kidney. This was healthy, so he resected the twelfth rib subperiosteally, divided the fatty capsule of the kidney, and pulled it on one side. The suprarenal capsule was healthy, and there was no pus in the subphrenic space. A prominence was felt through the peritoneum at the fovea renalis hepatis, which, on being cut into, proved to be a gumma. This was extirpated. Both fever and pain ceased at once and the patient recovered. This method of freeing the posterior surface of the liver could be made use of if the ligaments of the kidney allowed sufficient movement.

Austria.

[from our own correspondent.]

Vienna, February 26th, 1904.

Pityriasis Follicularis Chronica.

Neumann presented a young man, æt. 28, with pityriasis follicularis chronica. Over the whole body, but more particularly the trunk, there were brown coloured elevations about the size of peas, with a covering of thick scurf which, when rubbed off, left a red, granular, efflorescent base. The lymphatic, inguinal, and crural glands were all swollen, although the mucous membrane was in a normally healthy condition. This condition of the mucous membranes, with the hæmorrhagic appearance under the dry covering, were strong evidence against syphilis, of which nothing could be gleaned from the history of the case.

Then psoriasis vulgaris was excluded by the absence of the shiny covering and the presence of the hæmorrhagic condition just described. He had had the case under his observation for the last ten years.

Histologically the disease is an inflammatory process of the cutis, which has gone on to a true para-keratose state. The affection recovered under the use of ung. Wilkinsonii.

Neuro-Fibroma.

Ehrmann showed two cases of neuro-fibroma of the skin. The tubercles or tumours removed ranged from the size of a pea to that of a bean, of soft consistence, jutting forward with muscular movement as if from a pedicle. They contained pigment, and were associated with skeletal anomalies and slight psychical defects.

Riehl remarked that these cases were not simple growths from the nerve sheaths, but must be considered hereditary vegetations in a wider sense.

Ataxia.

Röth brought forward a case of tabetic ataxia, which he had successfully treated with faradic electric baths, followed by Fraenkel's ataxia gymnastics, the principle of which is to teach movements of the muscles through the sense of sight.

Barlow's Disease.

At the Gesellschaft for Children, Weiss showed a female child, æt. 4½ months, with the so-called Barlow's disease. The child was at the breast, and weighed 5,040 grammes, or 12·7 lbs. For three weeks it had suffered from dyspeptic stools and eczema intertrigo; the lower limbs were well developed. Without any apparent cause a swelling about the size of an orange appeared on the right side of the face on the upper maxillary bone, with a broad base. It was movable with difficulty and generally hard in consistence, although deep fluctuation could be felt on the apex of the swelling. The skin was glazed but could not be lifted up. In parts the surface had spots as if congested; and the

whole swelling seemed to have no pain. An exploration syringe was driven into the fluctuating part, but nothing but a small quantity of fluid sterile blood was obtained. A little later a quantity of blood exuded from the lower eyelid, which was repeated in two days, the blood being of a dark colour. This bleeding afterwards became more frequent from mouth, eyes, and nose. Cranio-tabes was not a prominent feature of the case. The soft tissue of the cheek conveyed the opinion that it was a traumatic swelling having its origin in the subperiosteal structure. From the age of the child and the subsequent hæmorrhage from skin and mucous membrane he was led to the conclusion of Barlow's disease. The most successful therapeutics for this was change of diet for the mother and antiscorbutic adjuncts for the child.

Kassowitz agreed with the diagnosis, but felt some misgivings about the etiology, which was often attributed to the malnutrition of the child, particularly in those cases where children were fed with sterilised milk. He confessed that the disease was very seldom met with in Vienna, although this could not be averred of all Austria. He did not quite agree with the opinion that the change of food was a success, as he often thought better air and anti-rhachitic treatment was more effectual than change of food alone. His reason for thinking that the disease had a rhachitic basis was the contrast of its rareness to the frequency of rhachitis.

Neurath asked if the probing needle struck against bone. This, he thought, would prove its subperiosteal origin. He thought the mobility of the tumour, and the site of the swelling, was against Barlow's theory of the disease.

Knoepfelmacher said he had a child about ten months under observation, in which a similar hæmorrhage occurred in the cheek. The histological examination proved no connection with the periosteum. After one cheek healed the same hæmorrhage occurred in the other cheek. It was confined entirely to the soft tissue.

Weiss replied that he had no other opportunities to prove that the swelling was subperiosteal, although the Röntgen rays and exploration tended to that opinion.

NUMBER OF PRACTITIONERS.

The number of medical men practising in Austria has increased from 11,339 to 11,689, or about 3 per cent. The greatest increase is in Lower Austria, which has risen from 3,325 to 3,454. Then comes Bohemia, Galacia, &c. Of the capital towns, Vienna comes first with an increase from 2,576 to 2,721, while Prague has 538 to 558.

The Operating Theatres.

GUY'S HOSPITAL.

OPERATION FOR THE MECHANICAL OBSTRUCTION OF THE LARGE BOWEL RESULTING FROM CHRONIC CONSTIPATION.—Mr. ARBUTHNOT LANE operated on a man, æt. 38, who had for many years suffered from severe constipation, his bowels not being opened at times for a week, in spite of constant drugging. The chief reason which made him think of surgical treatment was the constant abdominal pain with which this condition was associated; this pain and discomfort made his life a burden to him, and rendered him quite unable to do any regular work. As this was clearly one of those cases of mechanical obstruction of the large bowel, consequent on constipation, which Mr. Lane has described in the *Lancet* of January, 1903 and 1904, he proceeded to make a vertical incision just a little to the left of the middle line of the abdomen. The intestines were seen to present that condition of inactivity and plasticity which is constantly seen under these circumstances. The ileum entered the left side of the true pelvis, where it opened at once into the cæcum, which was enormously elongated and considerably distended, occupying the bulk of the true pelvis. Emerging from the pelvis it ran upwards and to the right on to the iliac fossa and loin, where it was tightly bound down, and its lumen very considerably obstructed by the presence of stout bands and adhesions. He divided these bands and adhesions very freely, liberating this part of the bowel from their constricting influence. Then he examined carefully the mechanical condition of the altered cæcum, and, from the knowledge he had gained previously of surgical interference in these cases, he knew that the mere division would only give temporary relief, since the adhesions would re-form almost at once when the freed bowel fell back into its original position. He, therefore, decided to disconnect the large bowel. This he did by bringing out the sigmoid, to effect which it became necessary to divide abundant adhesions which had shortened up the meso-sigmoid externally and had pinned down the sigmoid into the iliac fossa. He effected a lateral anastomosis between the end of the ileum and the sigmoid, after which he divided the ileum between its terminations and the newly-formed anastomosis. It was of interest, he said, to point out that the appendix had become obliterated in the whole of its length; it was stretched over the cæcum, to which it was adherent. It was not interfered with. Mr. Lane said that these mechanical conditions of obstruction of the large bowel, causing symptoms of septic absorption of a more or less disabling or disagreeable character, and very often associated with pain of a griping character, and with much soreness of the abdomen, were very common, and often with evidence of damage to the appendix. The only doubt generated in his mind in dealing with these cases, he remarked, was whether the freeing of the large bowel from the adhesions and bands was likely to be followed by permanent relief from the several symptoms, or whether it was not wiser at once to disconnect the greater part of the large bowel, and especially that portion of it which forms the cesspool of the gastro-intestinal tract, so effectually disposing of any recurrence of the patient's symptoms. He pointed out that in the earliest operations which he had performed he had been satisfied to make a very large anastomosis between the ileum and sigmoid or rectum, removing portions of the circumference of each so as to obviate the passage of fæces into the cæcum. He, however, found that when the cæcum and sigmoid were permitted to become loaded up the result was that material passed out of the combined ileum and sigmoid into the ileum beyond the anastomosis, and so into the cæcum, producing for the time being the old painful symptoms. This he obviated by again opening the abdomen and dividing the ileum beyond the anastomosis, so rendering any recurrence of the painful symptoms impossible. He believed that the individual suffered no appreciable loss from the fact that the large bowel down to the level of the aperture in the sigmoid was totally disconnected. On the other hand, besides a very marked improvement in the colour and complexion of the patient, the weight, energy, activity and intelligence of the individual, all improved steadily after the operation. He was convinced that the time was not far distant when this operation would be performed very frequently indeed, since a very considerable proportion of women and a much smaller proportion of men have not the energy to work the large bowel

efficiently, and, once its functions become altered by mechanical interference with its lumen in the manner ndicated, the absorption of products from the large bowel assist in thoroughly poisoning the system and reducing still further the capacity of the several organs and tissues of the body to carry out their normal functions. In addition to this it was hardly necessary, he said, to point out what he has often called attention to before, that the interference with the mechanics of the appendix, which results from loading of the large bowel, and the consequent formation of adhesions, was a matter of serious importance, constantly endangering the life of the individual. Of course, he added, the more rational way would be to make women lead natural and healthy lives, keeping them in the open air, supplying them with suitable foods, &c., so rendering them capable of performing satisfactorily their physiology and of producing vigorous and healthy offspring, and so being efficient members of a well-organised society; but, as it is, women are practically a hopeless failure in a large proportion of cases; civilisation has ground them down into the poor, ill-developed creatures they often are, totally unfit to perform satisfactorily that function for which purpose they exist, and to carry on the physiology of the rest of their body in anything approaching a normal manner. This degeneration, he thought, must of necessity increase, since the intelligence of the nation is such that the only remedy it can find is to make an excessive demand upon the capital energy of women, both as regards their brains by what is called education, and upon their muscular system by what are called games. They are obviously both disastrous in the extreme. The educationalists, or rather those on whom the care of these unfortunate young creatures devolves, seem to forget that the girl is too often mortgaged up to the hilt by the demands of her sexual apparatus, and having met that demand, more or less unsatisfactorily, she has no energy left to expend beyond bearing a fairly normal mechanical relationship to her surroundings.

One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX"

WEDNESDAY, MARCH 2, 1904.

THE PLAGUE OF ADVERTISEMENT.

It is not so long since Sir Crichton Browne spoke at a medical dinner on the evils and dangers arising from the licence permitted to advertisers in the daily press. And, if we remember aright, it was his idea that the insertion of advertisements of a certain type should be controlled by a Press Censor, inasmuch as they constituted a direct danger to the public weal. This danger is real, not only from its moral but also from its physical aspect. The crass ignorance shown in many of these announcements is matched only by the impudence with which they herald to the public the specific potency of certain wares, which are asserted to cure every disease or affection of every organ of the body. It is a matter of congratulation that some journals have refused to open their columns to a notorious form of advertisement, which is merely a thinly-veiled inducement, to those who may be desirous of using them, to resort to dangerous agents to effect illegal objects. How many women suffering from affections of the genitalia owe their diseased pelvic states to the frequent use of such "remedies" it would be difficult to estimate. There is also a class of advertisement, by pamphlet or circular, or through the press, which assumes a technical and intimate acquaintance with the affections of some special organ, all of which are supposed to be cured by the exhibition of that particular medicine, appliance, or mode of treatment which is being proclaimed to the public as an infallible remedy. It is an easy matter to find someone who will express in the suggested terms the required eulogium on the efficacy of the vaunted "cure." In fact, there is an art and science in the manipulation of such advertisements which secures a fair livelihood for those whose services are at the disposal of some enterprising charlatan. A cynic might say, in the words of Dean Swift, "If you like your security, down with the dust!" and if people will rush blindfold for every miraculous nostrum or mysterious appliance they hear of, they must take the consequences. But there is a serious side to this trafficking with human life and health. Sooner or later, in a certain proportion of cases, the deluded victims find that the maladies which they had for a time persuaded themselves were being mitigated or cured had only strengthened their hold, and they are at last forced to seek skilled advice. They then awake to the fact that money has been wasted and time of priceless value lost, and that organic conditions are now present which are beyond amelioration or cure. It is not, however, in the exhibition of drugs only that we find the most flagrant examples of this dangerous risk to the health of sensitive organs. Uneducated people, who are utterly ignorant of the delicate and transitional phases which mark the borderland between that which is physiological and that which is pathological, as, for example, in the tunics of the eye, more especially the retina, where they are associated with disturbances of vision, undertake, with a mere knowledge of refractive aberrations, to treat visual disturbances. And perhaps no organ is more open than the ear to the assaults of the harpies who speculate in distress and suffering, drawing their handsome profits out of some "boomed" system of treatment, while no organ requires a nicer balance of judgment in

the management of its maladies, or a finer adjustment of means to ends than this. All the advances made in recent years in otology have tended to the more exact differentiation of the causes of deafness, and the experience and knowledge required for an accurate differential diagnosis are considerable. Both prognosis and treatment depend upon this. Yet various mechanical appliances for the treatment of affections of the ears are being ordered indiscriminately, after so-called "consultations." Pamphlets, interspersed with quotations from recognised authors, are plentifully issued, and popular descriptions of such physiological or anatomical facts as can serve the purpose are added to give point to the asserted potency of the electrical or other appliance from the sale of which some speculative company reaps its profits. And so in other matters, even more serious than the functional integrity of an organ of sense. "Institutions," with "professors," are springing up everywhere for "electrical," "high tension," "Finsen light," "X-ray," and "massage" treatment. The initial stages of grave nervous disorder, spinal arthropathies, ataxies, obscure cerebral changes in nerve tissues or vessels, secondary complications, in which other organs are involved than those in which the nervous disturbance is showing itself, are liable to be regarded as the results of "rheumatism," "gout," "general debility," "muscular weakness," and so forth. The skin affords a rich harvest to some of the "beauty doctors," whose audacity in prescribing for and treating various cutaneous affections perhaps almost surpasses every other class of the charlatan brood. We have said sufficient to draw attention to this multiform omnivorous canker, which demands closer attention in the proper quarters than it has hitherto received. Furthermore, the open effrontery with which names of certain medical men of repute are used to boom and puff these wares is a disgrace to the profession, and must be a cause of embarrassment and great annoyance to those whose names are thus so ruthlessly sent broadcast to the public.

PROGNOSIS IN HEART DISEASE.

THE Address by Dr. Barr, of Liverpool, on "Prognosis in Heart Disease," which we published in our last two numbers, will, we feel sure, have been read with the greatest interest. The problem that the Address deals with is one that faces the practitioner at every turn, and its interest is only equalled by its complexity. There must always be certain elements wanting in the basis of all human prognostications, and one is often tempted to think that because predictions are so often falsified in the event, that it is impossible ever to forecast with any degree of accuracy. This, however, is not so, if primary factors that go to make up a sound prognosis are in one's possession; and in medicine, if the diagnosis is well made, and the concurrent circumstances are carefully taken into account, our knowledge of the natural course of diseases will enable us often to form a pretty shrewd estimate as to the line likely to be pursued by a particular case. But without accurate diagnosis all prophecy as to the future is mere guess-work. For this reason Dr. Barr rightly laid emphasis on the importance of examining the heart as opposed to merely auscultating it, and weighty and sententious are his words, "I hold that the man who cannot diagnose any cardiac lesion independently of the existence or non-existence of a murmur has only half learnt his work." It is said of that great clinician, Sir William Jenner, that the deafness which in later life prevented him using his stethoscope to practical advantage never hampered his wonderful acumen in the diagnosis of cardiac affections. In speaking of co-existent mitral stenosis and regurgitation, Dr. Barr points out that in many such instances the auricle is so much dilated that the auricular systolic murmur is not produced, and the ventricular systolic murmur alone is heard. Thus the one-sided auscultator regards the case as one of mitral regurgitation alone, and is thus inclined either to take too favourable a view of the patient's future, or to attribute a graver significance to pure mitral stenosis than is justified by the facts. Proper regard to all the contributory circumstances, then, is due from the discriminating physician, and we venture to think that a good deal of the discredit that has been thrown on medical selection for life assurance has been incurred by hasty diagnoses founded on the hearing of a murmur. The life offices often complain that the examiner turns away a great many lives which are quite assurable, and no doubt there are many cases of organic heart disease whose risk is assessable that are often declined altogether. In fact, in no small proportion of sufferers from uncomplicated mitral regurgitation, in whom there are no secondary effects, a very moderate extra sum alone is called for on a limited term policy. Thus Dr. Barr recalls the case of a fellow-student of his who was afflicted with mitral regurgitation early in life, and yet has borne it with equanimity during thirty years of active practice. Few medical men cannot produce parallel cases from their own experience. Mitral stenosis is a far more serious affection, and yet a patient who develops it after puberty may have forty or fifty years of fairly good health before him. It is not, indeed, the physical signs of the lesion itself that give the clue to the after-history of the patient, but the collateral symptoms and the previous record. Aortic stenosis, the result of slight thickening or roughening of the cusps by rheumatic endocarditis, has of all forms of heart disease the most hopeful outlook; but aortic stenosis due to atheroma of the valves, associated with calcareous changes in the aorta, gives warning of a rapidly fatal issue. Most physicians will agree with Dr. Barr that aortic incompetence is the most serious of the valvular lesions of the heart, and it is surprising to read that the writer, Rosenstein, in Ziemssen's "Cyclopædia," should have expressed such an opinion as that "the prognosis as regards the length of life and activity of the patient is more favourable in aortic insufficiency

than in any other valvular disease." No doubt individual cases of unexpected longevity in subjects of aortic regurgitation are noted from time to time, as in Dr. Barr's patient, who led an active life for thirty-five years; but in this country, at least, they are relatively few and far between. On the other hand, we read with surprise the optimistic view taken by Dr. Barr with regard to the outlook in chronic myocarditis and fatty degeneration. Dr. Barr is probably correct in thinking that the right ventricle is more often affected by these lesions than is usually supposed, but it surely is unusual for a degeneration affecting so vital a structure as the right cardiac wall to run so chronic a course that the patient is able to enjoy fairly good health for many years. We ourselves have always felt that fatty degeneration of the heart was the first nail in the coffin, and that it would not be long before the rest were needed. Patchy degenerations are not always of great moment, especially such as occur as the result of acute myocarditis, but the senile progressive fatty changes must be considered of very grave omen. The key, we take it, of Dr. Barr's thoughtful and instructive address is to be found in the words, "Cardiac hypertrophy and dilatation, from whatever cause arising, are sure to be followed by degeneration, and the greater the hypertrophy the earlier does failure take place." The true estimate of the effect of a valvular obstruction or leak is to be found, first, in the effects produced on the cardiac structures themselves, and, secondly, on those of the other tissues and organs. Dilatation of the heart rapidly disorganises the circulatory apparatus, unless it be succeeded either by recovery or by hypertrophy; and hypertrophy itself is evidence of chronic embarrassment. The greater the embarrassment, the greater the hypertrophy, and hypertrophy is a process that can only act within strictly definite limits. The breakdown comes when those limits are over-stepped.

Notes on Current Topics.

"Dr. Jim."

The result of the recent Cape elections has led to another kaleidoscopic change in the career of this extraordinary man. Dr. Jameson now finds himself Prime Minister of Cape Colony and the chief adviser of His Majesty's representative in that turbulent State. Dr. Jameson's career alone would give the lie to the statement often made that the days of romance are over, for surely no Stevenson or Henty out of his fertile imagination could have evolved a creation more daringly at variance with the probabilities of every-day experience. Captain Kettle's vagaries are not a whit more startling than the new Prime Minister's own—a promising medical student, an admirable resident officer, a successful operating surgeon, the conqueror of a savage country, a capable Colonial administrator, a Commander of the Bath, the leader of a troop of raiders, a felon condemned to death, a prisoner in the dock before his own countrymen, a convict for years, near the point of death after a surgical operation, shut up during a prolonged siege, comforting the last days of his great friend, an active Parliamentarian, a Prime Minister. Can such a record as this be matched from the annals of our profession since the days of Dover, the old pirate who reformed his ways, practised as a physician, and invented pulv. ipecac. co.? The name of Jameson has stunk in the nostrils of a large section of his fellow-countrymen since his daring, unauthorised enterprise, but it says volumes for the respect inspired by his personality that he should have come out of penal servitude to be the leader of a great and patriotic party in the very Colony which felt the effects of the raid most severely. All people who have come in contact with him are agreed on one point—that he is possessed of a peculiarly lovable disposition. He has no personal enemies, even though he has many bitter political opponents. No one will deny the honesty of his convictions and intensity of his devotion to what he believes to be his duty, though it is universally admitted that the Raid, planned and executed as it was, was a hideous blunder. In spite of his fantastical career, Dr. Jameson is no adventurer, but a strong-minded man of great determination, and some people still feel regret that he should have abandoned surgery, of which he was one of the foremost exponents in South Africa, for the political arena. There is one other medical Prime Minister of the present day, M. Combes, but of him it cannot be said that he was instrumental in saving the life of his keenest opponent. It is an open secret, however, that Dr. Jameson was able to render such service to President Kruger.

The Eating of Rats and Mice.

The peculiar habits of the "Heathen Chinee" are at the present moment very much to the front in journalism. The point which appears to appeal most strongly to the ephemeral scribe as salient to his pungent pen is the matter of food. According to him, the average Chinaman feasts on rotten eggs, decayed shark, and birds' nests, after which he retires to sleep heavily after a few pipes of opium, the while he dreams of further delights in the shape of droves of rats and mice. As a matter of fact delicate cates of that kind would be far beyond the command of the Chinese coolie, who is one of the poorest men on the face of the globe. But why should the Western journalist, full of the superior pride of his new-born civilisation, condemn John Chinaman because he eats rats? Has not perchance the Eastern wisdom, hoary and ripened with a millennium of years, hit upon a perfectly savoury and sound source of sustenance in the common rat? In other words, why do the inhabitants of the New World not eat rats? During the siege of Paris the citizens paid high prices for rats as well as for dogs, cats, and any other town mammal. Perchance it was a similar stimulus of chronic hunger that first led the Chinese to take to rats and mice as staple articles of diet. Apart from prejudice there is no particular reason why we should not feed on our domestic rodents. Their flesh is delicate and savoury. The

possible objection that rats have recently been shown to be powerful agents in the distribution of the germs of plague and of other disease need not disturb the philosophic *gourmand*, for precisely the same observation applies to the flesh of all edible warm-blooded animals, and possibly or probably to some of the cold-blooded creatures as well. Thorough cooking, however, would sterilise the flesh of the rat as it undoubtedly does that of other animal food. Is it not possible that the patient intellectual prescience of the most ancient civilisation of the world has long ago solved these little problems as regards the eating of the rat, while we in the West are clinging to prejudices that it would be impossible to support with any degree of scientific candour ?

Popular Views of Cancer.

THE position of the medical profession with regard to cancer is very much to the front in everyday journalism. Every fresh scientific move is instantly unearthed from the medical journals and noised abroad through the length and breadth of the land, in many cases much to the discomfiture of the investigator, whose one aim is to avoid that kind of notoriety. There seems to be little chance, however, of arresting the modern curiosity of the man in the street with regard to the curability of his bodily ailments, especially of those that have hitherto been of a peculiarly deadly nature. It is quite understandable that the causation and the possible cure of cancer should exercise the greatest fascination over his mind, distracted as it has been in times past by many a grim tragedy, to which he himself may one day be similarly a victim. But the restlessness of the public imagination is not confined to the scientific aspects of the question. The correspondence columns of many newspapers are simply flooded with " cures " and theories of causation of cancer. An amusing instance of the kind appeared last week in a leading London journal, where a lay correspondent mentioned the case of a man who suffered from cancer of the lower intestine and fasted for four weeks. " It was the cancer that died." This sapient gentleman then sums up his views as follows :—" When the natural processes of life can go on, and except when a patient has been exhausted by operations, a cure may be effected by a spare diet of meal, fresh and ripe fruits, salads (uncooked), with an abundance of pure air night and day, a perfectly clean skin, and total abstinence from animal food. This remedy is of course, beneath the notice of the Cancer Research Society. They have given up radium, their latest and most absurd proposal, and are still looking through their microscopes, vivisecting animals, and spending the brewers' money." The writer does not date his letter, as might have been anticipated, from a lunatic asylum. It is to be feared he represents a large number of well-meaning but intellectually untrained persons who form the prey of the quack cancer curer. Meanwhile, it is reassuring to note that there is every prospect of radium securing a recognised position in the treatment of cancerous growths.

A German Quack in Court.

As regards quacks and quack medicines it is tolerably safe to conclude that they manage these things better in Germany. The law demands, for instance, that the composition of every patent medicine should be fully stated on the label of the containing bottle, jar, or other package. In that way the reflective Teuton has at least the opportunity of learning what drugs he is taking into his internal economy. Quack practitioners are dealt with by summary police methods. A laughable case is still occupying the Berlin courts, where a notorious quack doctor of Tilsit, Richard Schroeter by name, has been placed upon his trial. The quality of his methods may be gauged from the statement that he practised healing mainly by prayer. One case was adduced in which a young girl was made to pray that a certain coachman who had swallowed a thaler (about three shillings) should eject it in small change so as to avoid choking. Schroeter was called upon to demonstrate his powers of diagnosis on patients brought into open court. Put to this test he missed well-marked lung diseases. When told the patient also had an ulcer on one leg he replied that he had seen unmistakable symptoms of ulcer imprinted on the eye of the patient. In answer to a question from the judge he promptly referred the ulcer to the wrong leg. All this sounds like a scene from comic opera. The British public, however, before they laugh might do well to practise a little heart-searching as to the Eddys and the Dowies and the Viavis, and the quack curers of cancer, deafness, nerve disorders, and every other malady that flesh is heir to, all and every one of whom flourish on the credulity of their victims. Under the protection of a three-halfpenny stamp the Government sanctions the sale of poisonous drugs that the chemist would not be empowered to sell separately. The average Briton, however, swallows them all without knowledge and without reflection. Why should not Government forgo the patent medicine tax, which brings in a comparatively trifling sum ? Or, failing that, why should they not take a leaf out of the German book, and insist on the publication of the ingredients of every patent medicine ?

The Training of Soldiers' Sight.

THE Army Medical Service is waking up, or, perhaps, it would be more generous to say that the authorities are beginning to realise the vital importance of that branch of the Service, and the necessity of encouraging its scientific development. Upon the statement of the *Times* we learn that steps are being taken to introduce more generally into the Army a system of training for increasing the visual powers of soldiers and further developing their powers of observation in the field, which has already been tried under Field Marshal Sir Evelyn Wood, V.C., in the 2nd Army Corps. The purposes of the training now proposed are stated to be—To improve the soldiers' vision and develop his quickness of perception so that he may, under ordinary conditions, find his way about and locate an enemy without his presence being

disclosed. To train the soldier so that he may acquire an eye for country which will enable him to report accurately what he has observed, and instinctively to select the position which will afford the best cover and best field of fire and the most suitable lines of advance and retreat. To enable him, when fired upon from an unknown quarter, to judge the most likely position which an enemy may be occupying, and to teach him how to counteract the ordinary ruses and stratagems employed by an enterprising enemy in war. The improvement of the soldier's sight and powers of observation, it is suggested, can only be effected upon a system similar to that of the training he receives at school and at the gymnasium. The instruction should be individual and progressive, proceeding gradually from the training of the group or section by its leader to the higher training of the squadron, battery, or company by its commander.

Ventilation for Public Buildings.

The inquiry into the best method of ventilating the House of Commons made by the Select Committee appointed last year brought to light some very interesting facts and views. The House of Commons system of ventilation, which was designed by the late Dr. Reid, has often been held up in the past as a model of what such a system should be, and theoretically it was as perfect as it was mechanically ingenious. Yet the members were continually complaining of alternate draughts and stuffiness. More significant than either of these was the general experience that even when the system was working without a hitch a feeling of languor and oppression was felt by members sitting in the House. The Select Committee had before them a large number of architects, professors, and other experts, and their evidence is very instructive as applying to the value of mechanical systems of ventilation. The rules laid down in text-books of hygiene with regard to ventilation are very precise, and seem to leave no doubt as to how they should be adjusted to circumstances. The standard usually taken is that set by the proportion of carbonic acid gas in the air of the room, and this we have always been told should not exceed 0·6 per 1,000 by volume. Therefore, as fresh air contains 0·4 cubic feet of carbonic acid gas per 1,000, and as man gives off 0·6 cubic feet per hour, the quantity of fresh air needed per man per hour is 3,000 cubic feet. But this calculation only touches the fringe of the question. There are two other factors that are at least equally important. One of these is the quantity of organic matter in the air, and the other the number and quality of the micro-organisms. The air varies in its qualities enormously; and the air of Manchester during a fog, one of which deposited five tons of solid matter in three days some years ago, is hardly likely to have the same restorative effect on the breather as an equal quantity of air inhaled from the top of Mont Blanc. But let the mechanically driven air be as pure as may be, as free from bacteria and as free from organic matter as filtration can make it, there always remains a want of that indefinable but well appreciable factor—freshness. The invigorative and tonic effect of the air of one place and the depressing, enervating influence of another may be obvious to everyone, and yet chemically and physically the two airs may be indistinguishable. Probably one of the reasons why plenum and vacuum systems both fail to convey this quality of freshness in the air they supply is that the velocity and composition of the air is uniform, and the stimulus that currents of varying intensities produce is lacking. The place of the open window has not yet been taken by any mechanical arrangement for supplying air, and it does not seem likely that it will in the near future. One can hardly imagine Duncan saying of the air of any of our mechanically-ventilated buildings that it "nimbly and sweetly recommended itself unto his senses."

Plucky Rescue by Medical Men.

The saving of life is, of course, one of the essential and central motives for which the medical profession has been called into existence. Indeed, it has become so much a part of the professional career that the average medical practitioner accepts as a matter of course the fact that he has saved a patient from imminent death by the exercise of his skill and experience. At times it is given to medical men to save life in the ordinary civilian way, that is, by physical daring and presence of mind. In that way two members of the medical profession, we are pleased to place on record, recently distinguished themselves in Carnarvon Harbour. Drs. T. W. Clay and R. T. Ellis were walking together late at night when they heard a shout, and proceeding in that direction they met with an adventure which is thus described in the *Carnarvon Herald* of February 19th. "As they approached the Beach Yard, someone in the distance shouted for help, and both ran down to the end of the Mackenzie Pier. There they saw a boat with a rope attaching it to the railings. The night was very dark, and the tide low, so that it was impossible to see anything. They pulled the rope, and clutching to it they found a man, who was gradually slipping into the water. One of the doctors leaned forward—the other one taking hold of him, so that he could keep his balance—and grasped the man. Slowly they dragged him from his dangerous position. By this time the man was unconscious, and the two doctors, with considerable difficulty, carried him up the pier, and applied artificial respiration until he regained consciousness. They next called for help, but, none forthcoming, they carried him into the Sailors' Home, where he received every attention." It will be seen from the foregoing narrative that both gentlemen incurred great personal risk, which, in our opinion, deserves recognition not only from the Humane Society, but from the hands of Royalty itself.

British Medical Association and Medical Defence.

Since the British Medical Association underwent a radical change in its constitution a year or two ago, it has shown marked signs of vitality

in various directions which had been untried previously. There is a tendency to stretch the extent of its activity beyond purely scientific work, and to make the Association representative of the entire profession wherever unity of action is possible. From time to time we have commented on various proposals put forward in or by the Association, and though we have not approved of all of them, yet we think that the increased initiative shown by the branches, and the increased interest in professional matters shown by the Council are healthy signs of the intellectual activity of the profession as a whole. The latest scheme sent down to the Divisions for discussion is in reference to the Association undertaking, in addition to its work in other directions, the duties and responsibilities of medical defence. The suggestion is that the Medical Defence Union, the London and Counties Medical Protection Society, and other like bodies should be invited to merge themselves in the British Medical Association so as to form one organisation for medical defence. In its finances the new department would be entirely independent of the Association, and members who wish to share the benefits of medical defence would pay a special subscription for the privilege. An obvious advantage of such a scheme is, that one thoroughly representative body would take the place of several minor organisations, and the unpleasant spectacle would be abolished of two defence societies taking up cudgels on opposite sides of the same case. We think, too, that the British Medical Association is the only existing body strong enough to assume such a position. The matter is one of great importance, and we are sure will receive the deliberation it deserves at the hands of the Divisions.

The Lungs of London.

IT is difficult to conceive what the vast Metropolis would be like were the numerous open spaces, large and small, with which it is happily dotted, to be swept away and their places occupied by grim structures of bricks and mortar. To the hygienic enthusiast the idea is repulsive, in the harmony which should exist in the æsthetic relationships of art and Nature it strikes a discordant note, while to the many thousands of weary and jaded toilers of the great city it would mean, if carried into effect, a deprivation of much that is beautiful and a distinct danger to health. Yet such is the greed for gain exhibited by certain speculative builders and landowners that some of our most picturesque square gardens, several of which possess historic associations, would be sacrificed in this fashion to-morrow if only the necessary legal building rights could be obtained. One such garden in Kensington, three acres in extent, has been sold for this purpose, and so it is that here a little and there a little these precious air-spaces, which have been termed appropriately "London's lungs," become consolidated by an exudation of building materials. The value of these areas as estates is enormous, and it is this fact which lures on those by whom the health of city-dwellers is seldom mentioned, except with a contemptuous snap of the finger, to acquire for themselves the right of increasing still further the already over-congested state of the Metropolis. The London County Council has, in many instances, done good work in rescuing some of our open spaces from immolation upon the building-altar, but it obviously cannot buy up all the squares in every part of London. Apart from mere sentimental considerations, the subject is one which is to be earnestly commended to the notice of legislators, and it is to be hoped that the present Bill which is before the House of Lords may receive sufficient support to strengthen the hands of the Council in securing protection for citizens in this matter.

A Small-pox Hospital Action.

THE not unnatural objection of the inhabitants of a locality to have a small-pox hospital planted in their midst fortunately does not often end in legal complications. Last week, however, the Nottingham Corporation appeared in the Chancery Division of the High Court of Justice to oppose an application for an injunction to restrain them from erecting a small-pox hospital in Bulwell Forest. The usual contention as to the conveyance of infection by aerial infection from such a hospital to the surrounding neighbourhood was emphatically advanced. Mr. Justice Farwell gave judgment with costs in favour of the Corporation. Having regard to the necessities of the case, as when persons attacked with the disease lived in one or two tenement rooms, he held that if the fact of public nuisance were established it would be no answer to private owners of houses who objected to say that the hospital would have to be placed elsewhere. When the question was whether the nuisance in fact existed or not, all the circumstances should be taken into consideration. In the present case he found that the result of the evidence was that the site of the present hospital was carefully chosen, and it had not constituted any danger to public health or to the plaintiffs' property. His lordship held it was no part of the functions of the Court to decide in what way the disease would be picked up. The importance of this judgment is crucial to the future of infectious hospitals. From a common-sense point of view such institutions must exist somewhere. The Nottingham case will apparently be carried to the Lords for further and final settlement.

The Science Schools at Cambridge.

IT is certainly interesting to note how the University of Cambridge has changed during the past thirty or forty years in the attention it has given to the development of Science in its system of education. Classics and mathematics were alone recognised as deserving any help or encouragement, less than fifty years ago. Science was a something that both these regarded with suspicion or contempt. Gradually things changed. The influence of such men as Gabriel Stokes, Lord

Kelvin, Sedgwick, Henslow, Humphry, and their successors made itself felt, and now the Natural Science Tripos has grown, and grown from half a dozen entries or so to be the most important tripos in the University. The Medical School fifty years ago had three or four students, indeed, in one year there was only one, to attend the lectures on materia medica or comparative anatomy. It was really to the attractions which physical science had for such men as Stokes and Thompson (Lord Kelvin) that the changes at Cambridge are chiefly to be traced. There is no doubt that the Medical School has followed, as the outcome of good tuition in the sciences of chemistry, botany, and physics has always been recognised in the preparation of medical students, and the advantages of good preliminary education, which could not be obtained at school, or at hospital, were appreciated by those who wished their sons to be trained on the highest lines for the work of the profession they were going to devote themselves to. In the teaching of every department of science it is necessary to organise a system different from that suitable for the study of mathematics or classics. In the branches of science it is by experiment, by demonstration, and by something far more than can be learnt from books that knowledge is to be acquired; and we hope that every support will now be given to the promotion of science teaching at the University of Cambridge, and that the work of tuition carried on there may be fully consistent with the character of the important buildings opened by H.M. the King this week.

Postural Hæmorrhages.

For the privilege of assuming the erect position man has had to pay the penalty of a special liability to various circulatory and other disturbances arising as a direct consequence therefrom. The term "orthostatic," as applied to different morbid processes, serves to emphasise the influence of posture in the production or aggravation of disease. It has lately been shown that albuminuria of the cyclical or physiological type is affected considerably by changes in position. The common-sense mode of treatment in almost all forms of external hæmorrhage is the immediate assumption of the horizontal position, whereby the heart's force is lessened. At a recent meeting of the Société Médicale des Hôpitaux, MM. Achard and Grenet reported the case of a tuberculous patient in whom symmetrical purpura appeared upon the lower extremities, which disappeared after some hours' rest in bed, but reappeared on getting up. To this internal hæmorrhagic eruption they have given the name of orthostatic purpura. As was pointed out by M. Apert, this feature is not unfrequently seen in many forms of purpuric rashes. The distance of the blood-vessels in the legs from the heart, and the fact that the blood in them has to return in opposition to the effect of gravity, combine to render the valves in the veins incompetent, to produce or aggravate a condition of varicosity, or even to cause slight ruptures of the thin-walled capillaries in this region. In other varieties of generalised cutaneous eruptions, especially when characterised by vascular disturbances or inflammatory changes, the lower extremities are found principally affected, and upon them the malady lingers the longest. The vertical position, no doubt, interferes somewhat with the equilibrium of the circulation, but, considering the confusion which already exists between the various forms of purpura, it would be inadvisable to employ a term which simply signifies one of the modes of its production as an appellation which would appear to indicate a special variety of the disease.

The Private Entree to the Viceregal Court.

As we go to press we learn that his Excellency Earl Dudley has been pleased to direct that the right of private entrée to his Excellency's Levées and Drawing-rooms, which was recently withdrawn from the Presidents of the Royal Colleges of Physicians and Surgeons should be restored to them. We have referred in recent issues to the withdrawal of the private entrée, and although we have felt compelled to express in positive terms our opinion on the action of those officials who were responsible for the withdrawal, we have all along taken up the view that whoever was responsible for an ungracious act, it was not the Lord Lieutenant. This opinion is strengthened by the gracious manner in which his Excellency has restored the right, and we tender to him, on behalf of the medical profession in Ireland, our thanks for the action he has taken. As a lay contemporary very well expresses it, it can matter nothing to anyone inside Dublin Castle whether the Presidents of the Royal Colleges enter the Castle by one door or by another, and this very fact intensified the sense of slight caused by the removal of a privilege, intrinsically valueless, but from the mere fact that it was a privilege, highly prized. The same contemporary expressed the hope that his Excellency would administer a severe "wigging" to those who were responsible for the unnecessary friction to which the withdrawal of the entrée gave rise, and would restore the latter to the medical profession. We know that his Excellency has discharged the latter task, and perhaps we may be forgiven if we express the hope that he has also discharged the former.

PERSONAL.

Mr. Edred M. Corner, B.S.Cantab., F.R.C.S.E., has, we are pleased to learn, been appointed assistant surgeon to St. Thomas's Hospital.

The Lord Chancellor has placed the name of Dr. George Fletcher, of Highgate, on the Commission of the Peace for the County of Middlesex.

We understand that Sir Lauder Brunton contemplates an early retirement from his post of senior physician at St. Bartholomew's Hospital.

It is with extreme regret we learn that Sir Samuel Wilks' general condition is causing great anxiety,

and his strength has not rallied in a satisfactory manner since his recent operation.

ROBERT BELL, Esq., LL.D., M.D., D.Sc., F.R.S., Acting-Director of the Department of Geological Survey, Canada, has been appointed a Companion of the Imperial Service Order.

AT the annual general meeting of the Royal Medical and Chirurgical Society, to be held on Tuesday next, the Council will propose the election of Sir Richard Douglas Powell as President.

DR. WILLIAM MURRELL presided last week at the Guthrie Lecture, which was given by Captain Hutton on the highly practical subject of the methods of restraint of refractory patients.

SIR SANDFORD FLEMING has presented Queen's University, Kingston, with a one-tenth interest in a coal mine near the Rockies. The proceeds will probably be used for the development of the medical school.

HIS MAJESTY THE KING has been graciously pleased to promise a donation of 100 guineas in response to the appeal of the Senate for funds to build and endow an Institute of Medical Sciences under the control of the University.

THE following have been appointed the examiners for the new diploma in tropical medicine and hygiene at the University of Cambridge :—Dr. G. H. F. Nuttall, Sir Patrick Manson, K.C.M.G., F.R.S., and Major Ronald Ross, C.B., F.R.S.

DR. EDWARD MALINS, the well-known Birmingham obstetric physician, was recently presented by his friends and admirers with a handsome series of testimonials, in recognition of twenty-five years' honorary service at the Birmingham General Hospital.

THE annual dinner of the medical officers of the auxiliary forces will take place at the Imperial Restaurant, London, on Friday, April 15th, at 7.30 p.m., under the presidency of Lieutenant-General Lord Grenfell, G.C.B., G.C.M.G., Commanding the Fourth Army Corps. Tickets, 10s. 6d. each, may be had from Lieutenant Montgomery-Smith, 36 Abbey Road, N.W.

THE King visited Osborne House on February 20th to inspect the alterations which have been made to convert it into a convalescent home for officers of the Navy and Army. His Majesty expressed his satisfaction with the changes made, and also spoke some words of encouragement to Miss Haines, the matron, who acted as his nurse during the historical illness that caused the postponement of the Coronation.

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

BELFAST.

BELFAST SAMARITAN HOSPITAL.—The annual meeting of this Institution was held in the hospital last week. The medical report was presented by Dr. John Campbell, F.R.C.S., who stated that the number of patients treated in the extern department of the hospital during the past year was 636, and the visits paid were 1,439. In the wards 172 patients were treated, and of these 113 required surgical operations. In supplementing the report, Dr. Campbell spoke of the work done in the two isolated cancer wards which had been added to the hospital by the munificence of the late Mr. Forster Green, and said that they had proved most useful.

BELFAST MATERNITY HOSPITAL.—The 110th annual meeting of this vigorous old institution was held in the Y.M.C.A. last week. The work of the hospital has outgrown the present premises, which it has occupied for 78 years, and it is hoped that in a few months a new building will be ready for occupation. Last year 326 patients were admitted to the hospital, and only one death occurred. The extern nurse attended 304 poor women in their own homes. During the year Dr. John Campbell resigned his post of honorary attending physician, and Dr. R. J. Johnstone was elected to fill the vacancy.

THE QUESTION OF FEES.—At a meeting of the Ballymena Board of Guardians last week, the question of medical fees was again under discussion. The former resolution of the Board not to pay temporary substitutes of medical officers more than £2 per week was rescinded, and it was agreed that Dr. Davison should be paid £9 9s. for three weeks' duty.

DEATH OF SIR JAMES MUSGRAVE.—Much regret is felt in Belfast at the sudden death last week of Sir James Musgrave, Bart., who has been not only a prominent figure in municipal affairs for many years, but has shown special interest in the furtherance of scientific education. A few years ago he gave a sum of £5,000 to the Queen's College to endow a Chair of Pathology.

Correspondence.

[We do not hold ourselves responsible for the opinion of the correspondents.]

ALOPECIA AND DENTAL CARIES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My trenchant critic, "M.R.C.S.," not having condescended to furnish the quotations establishing the dogmatic assertion that "enamel and dentine are incapable of physiological and pathological activity," I have referred to several standard works on the subject. Sewell ("Dental Surgery," fourth edition, p. 53) says: "By very careful decalcification of marsupial enamel, however, a considerable substratum of organic material is left after the complete removal of the lime salts, and this substratum is seen to correspond perfectly in structure and general appearance with the original cytoplasm of the ameloblasts." Could Tomes, "M.R.C.S.," or any other man of scientific training venture to assert that the organic matter in question had no possible active physiological or pathological relationship to the hard dental tissues? Organic matter exists in dentine and enamel, and I am aware of no exact demonstration that its nutritive and absorptive, aye, and reparative functions, are not exercised. How about absorption of hard dental tissue in the roots of the milk teeth? There is an instance, anyway, of where the deposit of dentine has not been permanent and final.

It is an acknowledged fact that union of a fractured tooth may take place. An instance has come under my own notice in the course of ordinary practice. Smale and Colyer ("Diseases of Teeth," 1901, p. 188) say such union may take place. Can "M.R.C.S." reconcile his dogmatic position with the repair of so serious an injury as the fracture of a tooth?

Unfortunately I have not the works of Sir John Tomes at hand for reference, but I feel confident that so scientific a man made no such dogmatic statement as that attributed to him by "M.R.C.S." By the way, the printer made me say "Sir John Turner" in my last letter instead of "Sir John Tomes."

It is to be regretted that a correspondent who strikes so hard should fall out at the first round after inviting a contest.

I am, Sir, yours truly,

MEDICUS SENEX.

London, February 29th, 1904.

Obituary.

SIR EDWARD SIEVEKING, M.D.Edin., F.R.C.P.Lond., K.B.

WE regret to announce the death of Sir Edward

Sieveking, Physician Extraordinary to the King, on the 24th inst. Edward Henry Sieveking was born in London in 1816, and was a son of a merchant of the same name, himself a descendant of a family well known in Hamburg. The son was educated at University College and Edinburgh, graduated as M.D. of the Edinburgh University in 1841, and settled in London to practise, becoming a Fellow of the Royal College of Physicians in 1852. He joined the staffs of St. Mary's Hospital and of the Lock Hospital, to both of which he was consulting physician at the time of his death. He was also for a time physician to the National Hospital for the Paralysed and Epileptic, and Physician in Ordinary to Her late Majesty Queen Victoria, as well as to His Majesty King Edward VII. when Prince of Wales, and was appointed Physician Extraordinary to His Majesty in 1901. Dr. Sieveking was for some years editor of the *Medico-Chirurgical Review*, and wrote much upon diseases of the nervous system, of which he had large experience at the National Hospital. He invented the æsthesiometer, for determining the tactile sensitiveness of the skin in different regions of the body. Among his works may be mentioned "Croonian Lectures on Epilepsy Delivered before the Royal College of Physicians," and editions of "Romberg on Nervous Diseases" and of "Rokitansky's Pathological Anatomy," both prepared for the Sydenham Society. Dr. Sieveking received the honour of knighthood in 1886, and he was a Knight of Grace of the Order of St. John of Jerusalem. He married in 1849, Jane, daughter of the late Mr. John Ray, J.P., and one of his sons is also practising as a physician in London.

The funeral took place on Saturday at Abney Park Cemetery, and a special service was, previous to the interment, conducted at St. Thomas's Church, Portman Square, by the Rev. Ralph P. Thompson. Mr. Dyce Duckworth, Dr. Verrier, Mr. Douglas Powell, Sir William Church, Dr. Charlton Bastian, and Dr. Robert Farquharson, M.P., were among those who attended, and the British Medical Association, the College of Physicians, the University of Edinburgh, and other bodies were represented. Mr. and Mrs. Herbert Forbes Sieveking and Miss Sieveking were the principal mourners. The King has sent a letter expressing his sympathy.

THOMAS DAWSON, SEN., M.R.C.S.

We regret to record the death of Mr. Thomas Dawson, who for many years practised in Rodney Street, Liverpool. He was in his eighty-sixth year, and died at 33 Alderley Road, Hoylake, where he had been living in retirement for several years. Apart from his professional activities, Dr. Dawson at one time figured with some prominence in the life of the city. In 1866 he entered the City Council as a Conservative representative for Rodney Ward, in succession to Mr. C. J. English, and two years after was defeated at the poll by Mr. David Campbell. In 1870 he attempted, unsuccessfully, to regain the seat, his opponent being the late Mr. P. H. Rathbone. For about forty years Mr. Dawson was a member of the Liverpool Lyceum, and in 1873 was elected president of the institution. He obtained the diploma M.R.C.S.Eng. in 1842.

Medical News.

The Finances of the Meath Hospital.

In the House of Commons last week Mr. Clancy asked the Chief Secretary whether he would state what was the contribution out of the county cess or the Poor-rate, by the governors and subscribers, and from any other source towards the maintenance of the County Dublin Infirmary in the years 1897 and 1898, and what was the proportion of the contribution out of the county cess or Poor-rate towards the building of that institution. Mr. Wyndham, in reply, gave the following figures as the sources of income of the Meath Hospital and County Dublin Infirmary for the years ended March 31st, 1897, 1898, and 1901:—County presentment (1896-97), £1,000; (1897-98) £1,000; (1900-01), £1,000. Contributions from governors and subscribers, £1,487, £1,995, £1,622. All other sources, £3,249, £2,831, £2,992. Totals: £5,736, £5,826, £5,614. Mr. Wyndham further stated that in the report of the Dublin Hospitals Commission, which was presented to Parliament in 1887, the hospital, as it was then reported upon, was built at a cost of £12,876, partly contributed by private subscriptions and partly by grants from the grand jury. The latter grants, he understood, amounted to £4,788. No grants have since been made from county sources for building purposes. A further sum of £17,393 has been expended on new buildings since the date of the report, all of which was privately provided.

Central Midwives Board and Pupil Midwives.

At a meeting of the Central Midwives Board on February 25th, Dr. F. H. Champneys in the chair, the following business was transacted:—A letter was read from the President of the Royal Academy of Medicine in Ireland setting out the difficulties that would be experienced by the Irish Chartered Maternity Hospitals in enabling their pupil midwives to comply with the rules of the Board as to personal delivery of twenty cases and a ten days' puerperium. A copy of the following resolution of the Section of Obstetrics, adopted by the General Council, was enclosed: "That in the opinion of the Obstetrical Section of the Royal Academy of Medicine in Ireland, any women holding the nursing certificate of the Irish Chartered Maternity Hospitals should be deemed to have complied with the rules of the Central Midwives Board regulating the course of training of pupil midwives, and should be eligible to present herself for the examination of the Central Midwives Board." After consideration of the foregoing, it was resolved: "That having considered the letter addressed to them by the President of and the Secretary of the Royal Academy of Medicine in Ireland, the Board regret that the suggested alterations were not brought to their notice before the rules were sent to the Privy Council, as, having been approved by that body, it is impossible for the Board to alter them." The question of framing a scheme of examinations to be instituted by the Board was referred to the Standing Committee for consideration and report, and other routine business was transacted.

The Poisoning at Portsmouth Asylum.

The inquiry into the circumstances attending the deaths of four female inmates of the Borough Asylum, Milton, Portsmouth, to whom sleeping draughts were administered on February 3rd, was concluded last week. The evidence of the borough analyst and the public analyst for Hampshire as to the analysis of the one draught which was not given but was similar to those administered showed that it contained 192 grains of chloral hydrate to the fluid ounce. Dr. Lysander Maybury stated that in his opinion the four women died from an overdose of chloral hydrate, and that the drug was more effective on account of the diseased state of the internal organs, as all the patients were suffering from inflammation of the lungs. The jury found that death resulted from chloral hydrate poisoning severally administered in the four sleeping draughts, the result of misadventure, and they were of opinion that all dispensing should in future be performed by fully-qualified persons only; and they also regretted that the person or persons who last filled the dispensing bottles had not had the courage to admit the act.

Sanitas.

At the annual general meeting of this Company, held on Wednesday last, Mr. C. T. Kingzett, F.I.C., F.C.S., the Chairman, called particular attention to the "Pine-Oxygen" treatment of consumption and lung and throat affections which had been elaborated by the Company, and he anticipated a growing demand by the medical profession for Sanitas Oil and Sanitas Fumigators and Inhalers, which appliances are associated with that treatment. It was pointed out that this treatment of consumption is inexpensive, and is within the reach of the very poor, while it does not necessitate residence abroad and obviates the rigours of the so-called open-air cure.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

RUPTURE OF TUBAL PREGNANCY ON THE NINETEENTH DAY.—A CORRECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the account you publish of the above case, notes of which I read before the British Gynæcological Society, the name of Dr. Gordon Hogg is inadvertently substituted for that of Dr. A. J. Hogg, of Ealing.

I am, Sir, faithfully yours,
WILLIAM DUNCAN.

REDIVIVUS (Hampstead).—We doubt if you will find a single supporter of any standing among the medical profession in your condemnation of the antitoxin treatment of diphtheria. The experiments you mention were carefully conducted, but their conclusion has long since been generally abandoned.

THE DISCUSSION OF MEDICAL QUESTIONS WITH LAYMEN.

MEDICAL men will do well to avoid discussion of physiological problems, such as those relating to the use of alcohol and tobacco, vivisection and the like, with persons who lack proper scientific training. Dr. Oliver Wendell Holmes thus condenses his own views on this subject:—

"You know that if you had a bent tube, one arm of which was the size of a pipe-stem and the other big enough to hold the ocean, water would stand at the same height in one as in the other. Controversy equalises fools and wise men in the same way *and the fools know it.*

B. W. H. (Winchester). The poison administered to your cat was undoubtedly prussic acid. It is a curious fact that an animal poisoned with that drug will sometimes run a considerable distance, as, for instance, up and down several flights of stairs, before dropping down dead.

S. H. H. STEPHENSON.—We beg to acknowledge with thanks the exchange number of the *Ophthalmoscope*.

BRISTOLIAN.—There is an excellent volume dealing with the subject in the Medical Monograph Series (Bailliere).

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 2nd.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Specimens: Mr. A. Doran: Pregnant Fibroid Uteri removed by Operation. Dr. Addinsell and Mr. Walker (introduced by Dr. Addinsell): Demonstration of Microscopical and Lantern Slides showing Mitotic Changes in Cancer Cells. Papers:—Mr. H. Crippe and Dr. H. Williamson: Two Cases involving the Question of the Site of Impregnation.—Mrs. Boyd: Two Cases of Abdominal Hysterectomy for Fibroids complicated by Pregnancy, with Specimens.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m. Dr. F. J. Smith: Cough and its Significance.

THURSDAY, MARCH 3rd.

RONTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Presidential Address:—Some Laboratory Notes of the ast Six Months.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, 72, Margaret Street, W.).—8 p.m. Lecture.—Prof. W. A. Potts: The Protection of Feeble-minded Children during and after School Age.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.).—5.30 p.m. Discussion on Obesity (opened by Dr. L. Williams).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. F. J. Smith: Cough and its Significance.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7, Fitzroy Square, W.).—5 p.m. Dr. F. Price: Mitral Stenosis (illustrated by cases). (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6.15 p.m. Dr. M. Dockrell: Sycosis. (Chesterfield Lecture.)

FRIDAY, MARCH 4th.

SOCIETY OF ANÆSTHETISTS (20, Hanover Square, W.).—8.30 p.m. Paper:—Dr. D. Buxton. Communications by the President (Mr. C. C. Braine) and Dr. Flux. Annual General Meeting.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases, Specimens, &c., will be shown by Dr. McBride, Dr. F. Potter, Dr. Smurthwaite, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street W.C.).—4 p.m. Mr. E. Clarke: Clinique. (Eye.)

Vacancies.

Aberdeen City District Lunacy Board.—Assistant Medical Officer. Salary £110 per annum, with board. Applications to C. B. Williams, Clerk, 20, Union Terrace, Aberdeen.

Brentwood Union.—Medical Superintendent of Infirmary and Medical Officer of Workhouse and Schools. Salary £300 per annum, with furnished residence in the Infirmary, rations, washing, &c. Applications to William Stephens, Clerk to the Guardians, Union Offices, Isleworth, W.

County Lunatic Asylum, Lancaster.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, washing, &c. Applications to the Medical Superintendent.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer. Salary £100 per annum. Applications to Thomas Hayes, Secretary.

Joint Counties Asylum, Carmarthen.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to Dr. Goodall, Medical Superintendent, the Asylum, Carmarthen.

London Fever Hospital, Islington, N.—Assistant to the Resident Medical Officer. Salary £120 a year, with board and lodging. Applications to the Secretary.

Manchester Children's Hospital.—Junior Resident Medical Officer. Salary £80 a year, with board and lodging. Applications to the Secretary, Gartside Street, Manchester.

Manchester Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to W. L. Saunder.

Nurses' Co-operation, 8, New Cavendish Street, London.—Lady Superintendent. Salary £140 per annum, with board and residence. Application to Committee of Management.

Roscommon Union.—Medical Officer. Salary £120 per annum, together with Vaccination Fees about £8, also to act as Sanitary Officer at a salary of £150. Application to J. J. Keeffe, Clerk of Union. (See Advt.)

Westminster Hospital.—Medical Officer. Salary £120 per annum. Applications to Sidney M. Quennell.

Appointments.

BULLMORE, CHARLES CECIL. L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer to the Falmouth Workhouse and to the Falmouth District by the Falmouth Board of Guardians.

COGSWELL, P. D., M.R.C.S., L.R.C.P.Lond., Medical Officer of the Stanton District in the Hinckley Union.

CROSSMAN, EDWARD, M.D.Durh., L.R.C.P.Lond., M.R.C.S., L.S.A., Medical Officer of Health for the Barton Regis Rural District Council.

GABB, H. S., M.B., B.S.Cantab., Certifying Surgeon under the Factory Act for the Hastings District of the county of Sussex.

GODWIN, HERBERT JAMES, M.B., B.S.Durh., F.R.C.S.Edin., M.R.C.S. Eng., L.R.C.P.Lond., Surgeon in Ordinary to the Royal Hants County Hospital, Winchester.

HARTIGAN, T. J. P., F.R.C.S.Eng., Assistant Surgeon to the Hospital for Diseases of the Skin, Blackfriars.

MAY, F. H., M.R.C.S., L.R.C.P.Lond., L.S.A., Medical Officer of Health by the Aston Manor Corporation.

RAINBIRD, P. H., L.R.C.P.Edin., L.R.C.S.Edin., L.F.P.S.G., Certifying Surgeon under the Factory Act for the Saxilby District of the county of Lincoln.

SMITH, M. HAMBLIN, M.R.C.S., L.R.C.P., Deputy Medical Officer, H.M. Prison, Manchester, H.M. Prison, Wandsworth.

STEWART, ROBERT SLOSS, M.D., C.M.Glasg., D.P.H.Camb., the Deputy Medical Superintendent to the Glamorganshire County Asylum, Bridgend, Superintendent.

WAUGH, P. M., M.B., B.S.Glasg., Certifying Surgeon under the Factory Act for the Rye District of the county of Sussex.

WEAVER, J. J., M.R.C.S., L.S.A., Medical Officer of Health of Southport.

Births.

BACKHOUSE.—On February 24th, at the Terrace, St. Ives, Cornwall, the wife of Charles F. Backhouse, M.R.C.S., L.R.C.P., of a son.

STEEL.—On February 23rd, at the Duke of York's Royal Military School, Chelsea, the wife of Capt. E. B. Steel, Royal Army Medical Corps, of a daughter.

WARRINGTON.—On February 17th, at 69, Rodney Street, Liverpool, the wife of W. B. Warrington, M.D., M.R.C.P., of a son.

WELLBY.—On February 25th, at Fletham, Liss, the wife of S. Wellby, M.D., of a daughter.

Marriages.

RICHARDSON—WOODLAND.—On February 24th, at Rye Lane Baptist Chapel, Henry Edward Richardson, L.R.C.P., M.R.C.S., of London, son of Charles Winterton Richardson, late Presidency Magistrate, Bombay, to Lilly, daughter of Thomas William Woodland, Forest of Dean, Gloucestershire.

Deaths.

CHRISTIE.—On February 25th, at Brompton Square, London, S.W., Robert J. Holder, eldest son of the late Robert Christie, M.R.C.S., aged 75.

DIXON.—On February 22nd, at 59, Granada Road, Southsea, James Deighton Dixon, M.B., Newcastle-on-Tyne, aged 50.

Original Communications.

ON

LATENT OR INTERMITTENT NASAL OBSTRUCTION.

By MAYO COLLIER, M.B., M.S.Lond., F.R.C.S.Eng.,

Senior Surgeon to the North-West London Hospital and Ex-President of the British Laryngological Association.

MR. PRESIDENT AND GENTLEMEN,—The object of my communication to-day is to ask you to consider with me a condition of things within the nose that, up to the present, has scarcely been entertained by rhinologists, and certainly not with the apprehension that this condition was one of any moment or worthy of much consideration.

I want to point out to you that there is a condition of things within the nose that is extremely common; that this condition, although extremely common, has escaped general recognition.

That this condition of things is potent for harm, and is a source of many of the affections found within the throat, ear, nose, and post-nasal space.

The terms latent or intermittent nasal obstruction are sufficiently descriptive of the condition I wish to discuss with you this afternoon.

I suggest to you, that apart from the various forms of nasal obstruction due to growths, outgrowths, deflections, or what not with which we are all familiar, there is a form of nasal obstruction that is more common and more harmful than all these put together. This form of nasal obstruction is latent, that is to say, it may come on in a nose that is physiologically perfectly patent, and in which there is nothing abnormal to be seen.

This form of obstruction may alternate with a condition of things in which the functions of the nose are perfectly performed, and yet for twelve hours out of the twenty-four the nose may be absolutely occluded, and the patient in a condition of extreme misery and discomfort.

This intermittent form of nasal obstruction often eludes recognition, and the surgeon is led astray because at the time of his examination the nasal chambers are perfectly free and patent, and the functions of the nose are perfectly performed.

I feel sure that no one present would resent the suggestion that more or less complete obstruction of the nasal chambers might be harmful to the individual, and might lead to ear, throat, or nose troubles. If you admit that constant nasal obstruction is in many cases a cause of ear, throat, and nose troubles, I am not straining your imagination when I ask you to believe that intermittent nasal obstruction is also powerful for harm in the same direction. Or, in other words, if continuous loss of the functions of the nose results in trouble in the nose, throat, and ear, I am here to contend that intermittent loss of the functions of the nose has a similar effect.

This, then, is the subject-matter of my remarks to you to-day.

In order to properly understand this question, we must have a clear idea of what are the functions of the nose, and how the physiology of this organ is related to the physiology of the surrounding organs, and to the economy in general. The nose has important relations with respiration, with digestion, with audition, with speaking and singing, with taste and smell, with sight and with the various emotional states.

The nose may also be looked upon as a respiratory organ in itself, as it is certain that a considerable interchange of gases takes place in its recesses and cavities. There is also some reason to believe that the nose is the safety valve of the brain.

In order to fully appreciate the effect of the loss of the functions of the nose, and the harm that may in consequence accrue to the individual, we must first be in a position to appreciate their value.

This can only be done by a careful survey and accurate knowledge of these functions as far as we are able.

In order to obtain this, we will discuss *seriatim* the nose in relation to the various functions I have enumerated.

And first of all with respiration, and so through respiration with the circulation and oxidation of the blood. As baldly stated in the physiology books the nose warms, moistens, and filters the air, but how this is accomplished the learned writers of text-books have not attempted to explain. At first it is a little difficult to see how a stream of air some thirty or forty cubic inches in volume can become warmed, moistened, and filtered whilst passing through the nose in the space of two seconds.

When, however, we examine the upper respiratory tract as a whole, we see that it is not a channel or tube of one uniform calibre, but that it presents several remarkable constrictions that alternate with equally remarkable expansions.

We then begin to see that these constrictions prevent the very thing from taking place that we are told does take place—*viz.*, that the air from the exterior passes slick through the nose from front to back, and on into the lungs in a solid, more or less cylindrical stream, and does not mix with its surroundings. This is manifestly incorrect. If we look at the upper respiratory tract, and view it as a whole, we shall be surprised at the variations that it presents.

Commencing with the external nares, we find that the vestibule becomes narrower as it passes inwards; and joins the nasal chamber opposite the nasal process of the superior maxillary bone.

The vestibule or inlet to the respiratory function is cone-shaped, and at its junction with the nasal chamber becomes so contracted as to constitute perhaps the narrowest point in the whole respiratory tract. It is curious to note that whereas the external nares are capable of expansion and contraction, the canal of the upper respiratory tract at its junction with the nasal chamber is rigid and unalterable, being surrounded by bony and cartilaginous borders. A limit is thus put to nasal respiration by the size of the anterior opening of the nasal chamber.

After passing this narrow spot in the respiratory tract we find that the canal expands in a remarkable

manner into the nasal chamber, which, with its recesses, constitutes a cavity of considerable dimensions.

These recesses must not be dismissed from our calculations when studying the act of respiration.

It is sure and certain as anything can be that these recesses act not only as resonance chambers to the voice, but as warming and mixing chambers; so that the air as it is admitted from the exterior in a raw and unprepared state is mixed with the contents of the nose and its recesses, and so made ready to pass on into the pharynx and upper tubes.

An observation I had the advantage of making on a healthy frontal sinus will go a long way in substantiating this fact.

I opened a frontal sinus for exploratory purposes, and being very careful I removed the button of bone without injury to the lining of the sinus.

At each inspiration the lining membrane was depressed and at each expiration bulged into the wound, proving incontestably that part of the contents of the nasal sinus is withdrawn during inspiration, to be replaced during expiration. The air then entering by the cone-shaped vestibule must do so with an increasing rate of speed till it has passed the narrows of the anterior opening. It must here lose much of its velocity, and becoming slowed down will distribute itself in all directions, as regulated by the sides of the delivery tube of the vestibule.

It is thus seen that as a stream of air it must be subject to and conform to the shape of the tract through which it passes, and that the rate of motion of the air will be an average between the rates of motion in the narrowest and widest parts of the respiratory tract.

Passing onwards we come to a second marked narrowing, that of the posterior nares. This is crescent-shaped and varies with the size of the posterior end of the inferior turbinal body. The cross section of this opening can only be a very small fraction of the cross section of the nasal chamber. Consequently the air in its passage backwards must be greatly delayed by having to pass this constriction, thus allowing time for the necessary warming, moistening, and filtering of the inflow.

Following on this constriction is a remarkable dilatation, that of the pharynx extending from the base of the skull to the upper opening of the larynx.

The nasal contents, having passed the posterior opening of the nares, lingers in the pharynx and passes slowly on, but with increasing speed, to the larynx. The act of warming, moistening and filtering is continued in the pharynx.

So far we have traced the inflowing air to the larynx, and can surmise that the anterior and posterior constrictions of the nasal chamber serve a very good purpose in delaying and slowing down the air in its passage through the nose.

The narrow anterior opening or inlet insures that the inflowing air shall be distributed and mixed with the nasal contents. The posterior constriction prevents the too rapid emptying of the nasal chambers by the powerful aspiration of the lungs.

It is curious to note the alteration in the positions of the contents of the respiratory tract from the commencement of inspiration.

At the commencement of inspiration the air in the bronchial tubes will pass in and fill the bronchioles and vesicles. The air in the larynx and trachea will follow on into the bronchial tubes, and the air in the pharynx will pass on and take the place of the air in the trachea and large tubes, whilst the air in the nasal chambers will flow into the pharynx, larynx, and trachea.

We thus see that the air passes in, and mixes with, and dilutes the impure reserve and residual air, but cannot displace it.

During expiration the impure expirate extrudes the contents of the pharynx and nose, and fills the upper respiratory tract. This, no doubt, undergoes considerable purification in the chambers and recesses of the nose in the interval before the next inspiration.

I would here remind you whilst on the subject of respiration that this is the supreme function of the economy. The circulation and oxidation of the blood, not only in the systemic but portal system, is dependent on respiration. It is not unreasonable to suggest to you that any interference with the functions of respiration, and so with the proper oxidation and circulation of the blood for a considerable period in twenty-four hours, must be harmful and baneful to the individual.

The functions of the nose are closely related to the functions of digestion, both directly and indirectly.

Directly by the interference with mastication that follows an obstructed nose.

A person with his nose occluded cannot shut his mouth sufficiently long to properly masticate his food, and consequently bolts the same before it is half divided, to the detriment of his stomach.

Again the congestion of the pharynx and post-nasal space incidental to, and associated with, nasal obstruction upsets the stomach in more ways than one. Directly by the amount of unhealthy mucus that passes into the stomach, and indirectly by the constant irritation of the pneumogastric centre by the branches of the pharyngeal plexus.

The insanitary state of the mouth that follows mouth breathing, and the amount of contaminated and dusty mucus that must pass into the stomach (or what has been properly termed oral sepsis) is a considerable disadvantage to digestion.

Seeing that the whole of the circulation of the liver and abdominal organs is carried on by the respiratory act, any interference with this must be of serious detriment to the absorptive functions of the alimentary canal, and so a fertile source of slow digestion and other forms of dyspepsia.

Digestion and respiration are so intimately associated that I seldom meet with a patient suffering from nasal obstruction in a marked and chronic form who escapes from symptoms of indigestion, sluggish liver, or other abdominal troubles. Now what relation have the functions of the nose to the eye? The nose is the drain of the conjunctival sac. Nasal obstruction will cause epiphora, and conjunctivitis and other troubles. The two functions are intimately and sympathetically associated. The same nerve and the same artery supply both.

Any irritation in the nose is responded to by flushing of the conjunctiva and watering of the eye. The nose is the guardian of the eye.

A strong light detrimental to the retina will cause sneezing, and so prevent further damage by altering the position of the head and casting the eyes to the ground, or closing them altogether.

Congestion in the nose will be followed by fulness of the retinal veins and congestion of the conjunctiva. The nutrition of the nose and eye are intimately associated. The ophthalmic and spheno-palatine ganglia are anatomically and physiologically closely related. Passing on to the relations of the nose to the ear, it is not surprising to find that these are peculiarly sensitive.

The middle ear or tubo-tympanum is developed from the nose by two finger-like prolongations. It is simply a prolongation of the nose cavity. The cavity of the nose and ear are practically one. Any increase or decrease of tension within the nose is immediately felt, and communicated to the contents of the ear.

It is not difficult to realise that whatever affects the main cavity of the nose will affect its various recesses and prolongations. The unity of the nose and middle ear must be taken into consideration and fully realised as the first and essential step in the proper understanding and treatment of many of the affections of this *cul-de-sac*.

There is little doubt that in normal nasal respiration both inspiration and expiration are felt in the tympanic cavity, and that a slight movement of the membrana tympani takes place inwards with inspiration, and outwards with expiration, the same as has been recorded in the frontal sinus.

In corroboration of this may be mentioned the fact that, when one is listening very carefully for a sound, the mouth is opened, and respiration is suspended or

carried on very gently by way of the mouth in order to annul (I suggest) the oscillations incidental to respiration.

The relation between the functions of the nose and the voice are peculiarly apparent.

Besides preserving the covering of this organ in a healthy condition, the nasal chamber is the delivery tube of the voice, as well as its resonator. The functions of smell and taste are almost entirely dependent on the patency and proper functioning of the nose, and must be entirely annulled if the nose be occluded. And, lastly, there are some grounds for supposing that the nose is the safety-valve of the brain, by acting as a drain to the arachnoid cavity. We know that the arachnoid sheath is continued through each opening in the cribriform plate and surrounds the olfactory nerves almost to their terminations. The confusion of intellect, the forgetfulness, the difficulty of concentrating the thoughts, the headache, the morning drowsiness, and other mental symptoms that are associated with nasal obstruction may well be due to increase of arachnoid fluid, and congestion following on nasal obstruction and the consquent arrest of the functions of the nose. There may be some reason, also, for believing that some, at least, of the large quantity of moisture that is taken up by the inspired air comes from the arachnoid fluid.

Again, the pathological conditions known as hydrorhœa, where pints of fluid are discharged from the nasal cavities, associated with polypi and other abnormal states can more easily be explained by the assumption of an outflow from the arachnoid extensions into the nose modified, possibly, by filtration. In order to remind you of the relation of the functions of the nose to the emotions, I would ask you to imagine any great actor with an obstructed nose and an open mouth. The emotional display of the face would be quite impossible, and the actor's efforts ruined. The relation of the nose to the sexual functions is well marked in some of the carnivora but may, I think, be altogether discarded when dealing with the genus homo.

Now, gentlemen, you will agree with me that the nose is not an unimportant or idle organ, and is well worthy of your best care and consideration.

I will now return to our main subject, and explain to you more fully what is meant by latent or intermittent nasal obstruction, the mechanism of its production, its diagnosis, and lastly, if we have time, I shall say a few words as to treatment.

I can more easily explain to you the exact condition to be known as latent or intermittent nasal obstruction by citing you one or more out of the large number of cases I have records of. In 1895 I was consulted by a medical man who gave the following account of himself. He was sixty-three years of age, for the last fourteen or fifteen years he had been troubled with his nose becoming occluded at night, and at other times. His general health, he said, was indifferent, he was easily fatigued, and suffered from flatulent dyspepsia, headache and deafness. His sleep was constantly disturbed at night, and he awoke in the morning unrefreshed and tired. He said for years he had suffered from catarrh in the nose and head, but lately things had become so much worse that he felt sure he would go out of his mind if something was not done for him. This gentleman was a tall, pale, liverish-looking person, with the look of suffering stamped on his face. I ascertained that he had treated himself with washes, snuff, and inhalations, but with little effect, and that he had been under the care of a distinguished physician who assured him his heart, lungs, and abdominal organs were sound. I found in his present condition nothing that one could lay one's hands on and label as disease. The throat was pale and anæmic, the interior of the nose was pale, and the mucous membrane was, if anything, anæmic. There was ample room for nasal respiration, and nothing abnormal or irregular was apparent, save one sign which I venture to suggest was the key to the whole situation. On either side of the septum there was the tell-tale hollow or groove, the exact cast of the lower turbinal body. Beyond this there was nothing to indicate that the nose had been anything but free night or day.

Well, gentlemen, with this physical condition of complete freedom of nasal respiration and the absence of anything abnormal with the nose, this patient was on the very verge of melancholia from the misery and discomfort of complete nasal occlusion so soon as his head was placed upon the pillow. The functions of the nose were here intermittently performed: for sixteen hours the nose was free, for eight hours it was closed. Yet this nocturnal occlusion was quite sufficient to affect and put out of gear all the correlated functions of the nose, and to bring the economy almost to a stand still. An almost exactly similar case was that of a barrister sent to me from Dublin by a member of this Association. These are extreme but typical cases, and happily, I am glad to say, are few and far between. The commoner forms of intermittent nasal obstruction present symptoms of less severity. In many cases there is only the slight hoarseness and morning cough, and difficulty in clearing the throat on rising in the morning. There may only be a tendency to flatulent dyspepsia or distension after meals.

The hearing may not be quite so good as it was, and the patient may tell you he thinks he is getting deafer, until he finds out he is suffering from a marked degree of deafness. This is constantly the only symptom of intermittent nasal obstruction. I believe that in intermittent or latent nasal obstruction we have a valid and sufficient explanation for the existence of that large class of slow, insidious, painful forms of ear trouble known as chronic progressive deafness. Given an occlusion of the nose for eight out of the twenty-four hours, and you have all the factors ready and able to produce occlusion of the Eustachian tubes, congestion of the tympanic cavity, and depression of the drumhead, and the subsequent physical changes known as sclerosis. This explanation is worthy of your consideration, and the more I live and learn the more assured I am of its soundness. I have on more occasions than one insisted that there is an intimate relation between intermittent nasal obstruction and the affections of the other recesses and extensions of the nose, and the same anatomical and physiological facts that govern the recess of the middle ear apply equally with all the other extensions of the nose.

The tympanic cavity and the antrum or frontal sinu are on all fours with each other. They have a common origin. Their lining membrane is similar and continuous, They are subject to the same variations in air tension and supply, and they are subject to the same affections. I have recently exhibited to you a case of frontal sinus trouble where the suppuration was kept up for three years by occlusion of the nostril on the same side from collapse of the wing of the nose, and enlargement of the turbinal body.

On reducing the turbinal body and supporting the wing, the suppuration promptly disappeared. Uncomplicated chronic suppuration of the accesssory cavities of the nose is induced and maintained by intermittent obstructions of the nose. This applies equally to the aural accessory cavity. The obstinate discharges from these cavities that continue sometimes after operations are to be explained when intermittent nasal obstruction is present. We have heard a good deal lately about the etiology and treatment of polypi. My experience is that when these growths are properly removed, and the nose properly ventilated, and nocturnal nasal obstruction prevented, they do not return. I have one case that illustrates my meaning perfectly.

I operated on a gentleman whom I exhibited in this room as a typical martyr to asthma relieved by clearing his nose from polypi. Well, these growths recurred and required removal off and on for eleven years. In the earlier periods of my treatment I took no account of the fact that he was completely obstructed at night time and yet was free during the day. The asthma was better when the nose was cleared, but returned with the obstruction. Some four or five years ago I operated on both lower turbinal bodies. I have never

had occasion to treat him medically since, and his nose remains perfectly free from polypi to this day.

I believe that intermittent nasal obstruction plays an important part in the production and recurrence of polypi. Much more could I say on this important subject, but the time at my disposal will not suffice for a more extended view. We pass now on to the subject of diagnosis. How do we know when intermittent nasal obstruction is present or not? If there is nothing abnormal to be seen in the nose, and if the functions of nasal respiration are perfectly and adequately performed, by what signs shall we be able to recognise this form of obstruction? In latent or intermittent nasal obstruction, the obstruction, as a rule, occurs at night-time when the head is on the pillow, and the body is more or less in a horizontal position. When up and about, as in sitting, walking, or standing, there is seldom obstruction except on passing from a cold to a warm atmosphere, and sometimes when drinking hot liquids or taking spiced or pungent meals, with alcoholic drinks. In the vertical position of the trunk, gravity retains the venous blood in the great vessels of the neck, chest, and abdomen. On assuming the horizontal position, the blood flows into the veins and sinuses of the head and neck, in response to the same force. When sleeping, the arteries become smaller in calibre, and the veins larger, so that the veins of the head and neck contain relatively more blood. The cavernous tissue and mucous membrane of the nose become, when lax and atonic, distended mechanically by the increased intravascular pressure caused by the mere inflowing of blood to these parts. The distended turbinal bodies approach the septum on either side, and press upon it so vigorously as to form a groove or exact cast of themselves, and completely to obliterate the lumen of the nasal chambers. The erectile tissue on the floor and lower part of the septum helps to complete this. The groove, then, is to be sought for and is undoubtedly evidence of the condition I am attempting to describe to you. It is indeed more than evidence, it is pathognomonic of intermittent nasal obstruction, and is the only objective sign that will present itself to you. With subjective symptoms of laryngeal, throat, nose, or ear trouble, and the objective sign I have described to you, you have all the evidence you require to make the diagnosis of intermittent nasal obstruction.

I place no credence on the answers of patients to the question as to the method of breathing at night. Some, very often the worst cases, will indignantly repudiate the suggestion that they breathe through the mouth at night, yet will in the same breath tell you that they awake with the tongue dry, and are always anxious for a cup of tea in the morning. The subject of treatment will involve much time and consideration, and as I feel I have already occupied a large measure of your time, and like yourselves am anxious and looking forward to the Presidential Address, I will postpone it to a more opportune moment. If in the remarks I have made I have given you any suggestions worthy of your acceptance, or set you thinking on this important subject, I shall be more than amply repaid for the anxiety and labour attendant on this communication.

THE DIMINISHING BIRTH-RATE:

ITS CAUSE, ITS TENDENCY, AND POSSIBLE REMEDY. (a)

By JOHN W. TAYLOR, M.D., F.R.C.S.,

Professor of Gynæcology in the University of Birmingham; President of the British Gynæcological Society.

(*Concluded from page 227.*)

PART II.

III.

WHAT will be the outcome for England in the future if nothing be done to check this and allied abuses of so-called modern civilisation? If I shall not weary you with statistics I would ask you to turn your attention for a short time to our sister nation, France, where (as in a magic mirror) one can apparently see the future of those countries in which the birth-rate tends to fall until the population becomes stationary, or even less than stationary, as it is in France to-day. (*a*)

In a remarkable paper written by M. Alfred Fouillée, of the School of Moral Sciences, in the *Revue des deux Mondes* of January 15th, 1897, we find the following account of the criminal statistics of France: "Since 1881—that is, from 1881 to 1896—the number of prisoners before the Correctional tribunals has risen from 210,000 to 240,000. Since 1889—or in 7 years—manslaughter has risen from 156 to 189, murder from 195 to 218, and sexual crime from 539 to 651.

"In addition to the general increase in criminality of all kinds, a sort of specialisation of crime, especially for acts of violence, is to be noticed. These belong more and more to a certain class, that of the old offenders. The number of these, which was 30 per cent. in 1850, is now 65 per cent. In short, during the last fifty years criminality has trebled itself in France, although the population has hardly increased at all.

"The saddest side of the criminal statistics is that regarding children and young people. From 1876-1880, while the misdemeanours of common law had trebled among the adults, the criminality of youths (from sixteen to twenty-four) had quadrupled, that of young girls had nearly trebled, and the number of children prosecuted had doubled. In the period 1880 to 1893 criminality has increased still more rapidly. To-day child-criminality is nearly double that of adults, notwithstanding that minors from seven to sixteen years only represent seven millions, while adults amount to more than twenty millions. In Paris more than half of the individuals arrested are under twenty-one, and nearly all have committed the more serious offences." According to M. Adolphe Guillot, the acts of the young prisoners are marked by an exaggerated ferocity, a special refinement of lust, and a bragging of vice that are never met with to the same degree at a more advanced age.

"Child prostitution is growing, and in ten years the number of children charged with prostitution was estimated at 40,000. In 1830 the number of suicides was 5 in 100,000; in 1892 there were 24 to the same number. By 1887 the suicides of children under sixteen years (formerly extremely rare) amounted to the number of 55. In 1896 we had 375 suicides of young people between the ages of sixteen and twenty-one, and the suicides of children under sixteen were 87."

These are facts written by a Frenchman for French readers in the best known French magazine of the day. (*b*)

If we like to extend our inquiry we find that these figures are taken from the national statistics, and are in harmony with other observations. "Since 1880—that is, during the last twenty years—the consumption of alcoholic drink in France has trebled, and France has passed from the seventh place in order of consumption of alcohol to the first." (Mr. Yoxall, M.P.)

The figures in Mulhall's "Dictionary of Statistics," though varying to some extent, are in rough accordance with these. According to this authority, we find that insanity is steadily increasing in France, and that the ratio of suicides has risen from 112 per million in 1880 to 205 (or nearly double) in 1885.

I do not want to press these figures beyond their bare legitimate application. In particular, with regard to alcoholism, this depends on many factors.

(a) Inaugural Address read at the meeting of the British Gynæcological Society, Thursday, February 11th, 1904.

(a) "In France during the past year, according to the returns of the Bureau of Vital Statistics, there were 25,998 more deaths than births, and 20,000 fewer births than during the previous year. The record shows only 827,297 births for a population of 39,000,000, though there was a slight increase in the number of marriages, and a slight decrease in number of divorces." (*Montreal Medical Journal*, December, 1903.

(*b*) A very similar or parallel article on the increase of crime in the United States (where "prevention" is exceedingly common) is written by Dr. Buckley in the *Century Magazine* for November, 1903.

and is very much governed by the legislation of the country regarding its sale. In England, for instance, there was a marked diminution in national expenditure after the Early Closing Act of 1872, and in France there has been a great increase since 1880, when, as I understand, the facilities for obtaining it were much increased.

But this does not alter the fact that after half a century of trial with an increasingly limited population France shows more and more a lowered and still falling moral average, a lessening virtue and strength, and an increasing national neurasthenia, which seems to crave and to need the help of constant stimulation in order to face the ordinary routine of life.

Here we see a great nation, a people and a land which, next to my own, I think I understand, appreciate and love better perhaps than any other, and to which I wish nothing but good; but a nation so bound by the fetters she has forged for herself that nothing but the life she has deliberately cast aside could apparently save her from her slow decay.

And is not this refusal of life by the French at the root of the deep anti-Semite feeling which otherwise would be so contrary to the frank spirit of the French? The Hebrew race, to their lasting honour, with very few exceptions, have not only kept themselves free from the vice of which I have been speaking, but, by reason of their laws and customs, are the most systematically temperate in their sexual relations of any nation or people I know.

Consequently, among them, the natural breeding of the better stock has never been interfered with, and in a country like France, the Hebrew seems to rise not only individually, but racially, among the people with whom he has his dwelling, until what appears to be an unfair proportion of responsibility and power and wealth rests in the hands of an alien race. When this is discovered, and the cause of it but dimly recognised, there cannot but be bitter feelings of jealousy and even hatred in the great mass of the nation among whom the Hebrew dwells, and it is not surprising that the power of combination and of number is sometimes unjustly used to overcome (if possible) the disadvantage.

So far, I have been dealing only with what is open to observation and experience. But may we not reasonably go a step further? What must be the future of such a society if degeneration goes on and the power of the democracy remains as at present or increases? So long as the race progresses the people can be trusted with the powers of Government, but when decadence has been going on for years, or even ages, what can be the final outcome of such democracy but anarchy and confusion?

IV.

In dealing, or attempting to deal, with the treatment of this grave national evil it is necessary to take a broad and yet sympathetic view of the problem.

It is one belonging essentially to the higher gynæcology, in which no false sympathy or lower obstetric platform must be permitted to interfere with what is really best for the individual and the race. And yet when we recognise that the whole force of modern civilisation, its honour paid to riches, its luxury, its frivolity, its impatience, its society, its manner of life, its very "neurasthenia" seems all more or less opposed to the cultivation of that true family life which is its best safeguard against decay, one needs indeed to temper judgment with a quick appreciation of all the difficulties encountered by every modern wife and mother, and to recognise the almost insurmountable obstacles for the Church, the State, and the Profession of Medicine to slowly overcome.

For, I think, the help of all is needed. The Roman Catholic Church teaches that prevention is a sin, and though this is altogether beyond my province, I would submit that no lower standard of sexual morality should be allowed by those who belong to another communion, and that every effort should be made by the religious and the moralist to inculcate a higher ideal, and a plainer and simpler standard of life.

In the State it might be possible to encourage this higher ideal by regarding the well brought-up family as one of the attendant qualifications for high distinction and honour, and, in addition, by some wide scheme of old-age insurance or pension, by better facilities for the higher education of children, and by some special remission of taxation to lighten the burdens of those who are bringing up large families to be a credit to themselves, and a lasting benefit to the nation.

Again, where further education is demanded, and legitimately demanded, by any profession or calling as necessary to full qualification, I would have the State rather jealously guard the earliest possible date at which productive work may begin. Part of the difficulties of our modern life seems to be caused by the ever-receding age at which such work is possible. In my own student-days many of us qualified at twenty-one, were earning our own living at twenty-two, and yet managed to keep up study and hospital attendance until taking the higher degrees at twenty-five or twenty-six. This may have been mistaken, but I am convinced it is a far greater mistake to keep a young man, with a man's vigour and ambition, from any real independent work through most of the years from twenty to thirty.

In the Medical Profession itself the evils of prevention, both immediate and remote, should be studied more closely, and explained to such patients as need direction and advice. No advice should be given in favour of it without special consideration of the subject in all its bearings and due consultation.

My own opinion is that while occasional abstinence in married life is perfectly allowable and may have, as I have suggested, a high moral hereditary value, no artificial prevention is advisable save that which is produced by operation, when deformity or grave disease imperatively demands it.

Certainly in the present day when septic diseases, as we know, can be reduced to a minimum and should be almost entirely avoided, when surgery can so effectually and safely deal with nearly every kind of difficult or dangerous labour, it is not the time for the fairly healthy parents of one child to shelter themselves behind the terrors and troubles of a first confinement, and demand some easy but evil way of further immunity.

But as civilisation increases, there can be little doubt that the susceptibility to pain increases also, and it may be that the mothers of to-day need a greater consideration and help, during the progress of pregnancy and lactation, than the mothers of former years. Very much more may be done during these periods by suitable advice, management, and diet than many imagine. In some cases, as I showed last year, repeatedly disastrous pregnancies may be changed into ones of healthy type and character solely by what amounts to a special and more liberal dietary before and during pregnancy; (a) and much of the partial collapse and ill-health that is apt to follow parturition and accompany lactation may be modified or altogether avoided by due provision and direction for the hygienic requirements of mother and child, particularly as regards rest and food.

In these ways, and especially by personal influence and example, the medical practitioner may do more perhaps than anyone else to reform the judgment and correct the practice of this and coming generations.

But when all this is said and done, there still seems to be needed some general awakening of the national conscience if any thorough and lasting change is to be hoped for. Let us be careful that the awakening is in the right direction.

One word of caution may be needed. Whatever may be the merits or demerits of celibacy as compared with marriage, statistics show, as I have already stated, that it has but very little practical bearing on the subject before us. "The birth-loss in the United Kingdom must be due to causes operating in the married life

(a) *British Medical Journal*, April 11th, 1903.

of its inhabitants." True celibacy, maintained, as it often is, for the sake of the better service of mankind, is worthy of the highest honour and may well be subject to a higher law than that of physiological increase. Many noted examples of this will occur to all as I speak, in every profession and of both sexes. These are vicarious fathers and mothers whose children far out-number the limits of a physiological family, and the lives they protect or encourage or save make for that "maximum of life" which is associated with the "maximum of virtue."

There is no reason to fear any high ideal of chastity or continence, and especially none when it is associated with the care of those forces which go for the defence of the nation and that child-life which is its future hope.

On the other hand, there is every reason to fear that debased ideal of married life which is secretly and insidiously working for the ruin of the nation's power and for the destruction of its hope.

Artificial prevention is an evil and disgrace—the immorality of it, the degradation of succeeding generations by it, their domination or subjection by strangers who are stronger because they have not given way to it, the curses that must assuredly follow the parents of decadence who started it—all of this needs to be brought home to the minds of those who have thoughtlessly or ignorantly accepted it. For it is undoubtedly to this that we have to atttribute not only the diminishing birth-rate, but the diminishing value of our population.

No truer words were ever said than those by Ruskin: "The maximum of life can only be reached by the maximum of virtue." Do they not carry with them another truth which has now become almost a demonstrable fact, that the prevention of life is always accompanied by moral deterioration?

And this evil harvest, for ourselves and for our children, is of our own sowing. Some, looking back on past history and bygone civilisations, have imagined that the rise and fall of empire follows some unalterable law, and that nations, like individuals, must necessarily suffer from senility and decay.

But it is not so. National decay or degeneration is by no means the inevitable consequences of age. Our modern ally, Japan, is an evidence of this. After a long and chequered history, quite as long or longer than our own, she has emerged in all the activity and strength of a second youth.

And it is interesting to note that this new-found power is directly associated in the mind of the Japanese with the knowledge of their own racial strength and power of increase; indeed, it is this which gives them—youth.

This is well shown by some recent remarks of one of their more prominent men. He writes:—"Japan is in no danger of race-suicide. . . The mothers are not shirking maternity as in other lands, and the result is that we can spare half a million of men a year for an indefinite number of years and not miss them.

"Barring Formosa and the Pescadores, we have less than 150,000 square miles of territory, of which eleven-twelfths is unproductive of food. Nevertheless, we have close to 50,000,000 folk to feed. Do you wonder that we are land-hungry—that we want elbow-room?" (Reported by Stephen England in the *Daily Mail* of December 23rd, 1903.)

In a somewhat different way the Hebrew race, to whom I have already referred, may also be cited as an example of an ancient people, old in every sense, and still not dying out. Conquest and dispersion have left their ineffaceable impress on the race, but they are with us to-day, not infrequently showing evident traces of centuries upon centuries of nervous training and development, of nervous wear and tear; possessing, too, a history of great achievement in music, art, and literature, corresponding to that development, and yet showing, so far as I am able to ascertain, no sign of real decay or loss of reproductive energy.

We have the same power with far better opportunities and a much brighter outlook. At no period in our history, perhaps, was there less reason for racial suicide, and, apart from this, for pessimism. All of us, both men and women, need a truer and braver conception of life. Life is entrusted to us—life and the power of life—and we should be ready to work, to suffer and to adventure greatly and cheerfully, for the honourable and wise employment of the entrusted capital.

"Then welcome each rebuff
That turns Earth's smoothness rough,
Each sting that bids, nor sit, nor stand, but go.
Be our joys three parts pain!
Strive and hold cheap the strain;
Learn, nor account the pang; dare, never grudge the throe."

I must confess when I hear of thoughtful men among the Boers in South Africa, military authorities in St. Petersburg, and Japanese in far Japan, noticing and counting on their own racial increase, and comparing this, kindly or unkindly, with our own comparative stagnation, I would like, if I could, to sting my fellow-countrymen into some proportionate sense of shame and duty.

My voice is weak, but in the responsible position in which you have so generously placed me, as the temporary head of a great British Society, which may well claim to be the greatest British authority on such questions, I am surely not overstepping my province if I ask for the grave interest of every Fellow in this important subject; if I ask, not so much for any following of my leadership as for the fullest independent investigation into all the facts, figures and arguments I have brought before you. For with us lies a great responsibility, and ours will be to a very large extent the blame if, in after years, the lamp of the Anglo-Saxon is found to be burning dimly.

SOME OF THE LIMITATIONS OF MEDICINE IN ABDOMINAL DISEASES. (a)

By G. P. CHAPPEL, M.D., B.C.Cantab.,
Physician to Out-Patients Tottenham Hospital.

THOSE morbid abdominal conditions, both acute and chronic, which are amenable to surgical treatment have, since the introduction of antiseptics, become so numerous that I only propose to touch upon those which are more commonly met with in everyday practice.

Stomach.—The remarkable advances in surgery which have been made during the last few years in the treatment of perforated gastric ulcer have robbed this fatal complication of much of its terrors. Every hour that laparotomy is postponed very seriously diminishes the chance of recovery. Patients who are the subjects of simple gastric ulcer are always liable to get relapses when surrounded by bad hygienic conditions. When repeated small hæmorrhages or a second large one occur, and the ulcer will not heal in spite of medical treatment, I think it is our duty to call in the surgeon. Another class of cases are those of chronic gastric catarrh in which the digestive powers are much impaired, and the recurrence of pain and flatulence causes much suffering. The process of lavage is very helpful in getting rid of the stringy mucus, and it is one which patients can soon learn to perform for themselves, but where this fails to give relief the question of performing a gastro-enterostomy should be seriously entertained. In malignant disease of the stomach, medical treatment is useless, except as a palliative.

Liver.—We may say broadly that the treatment of hepatic disorders belongs to the physician, with the exception of liver abscess and hydatids, both of which have to be distinguished from perihepatitis and hypertrophic cirrhosis. In the two latter the enlargement of the organ is uniform, whereas abscess and hydatids usually affect one or other lobe. The case becomes

---

(a) Abstract of a Paper read before the North-East London Clinical Society, at the Tottenham Hospital, Thursday, March 3rd 1 04.

more complicated, however, when these conditions are multiple.

The most common cause of *jaundice* is a catarrhal condition spreading up the common duct and causing obstruction by swelling of its mucous membrane. If pain be very severe, it is probably due to the passage of a gall-stone. Medical treatment must be anodyne. Solvents have been recommended in the shape of large doses of olive oil. A large proportion of autopsies show that gall-stones are frequently present in the gall-bladder without causing any trouble. Surgical interference is indicated under the following conditions—(1) When there are repeated attacks of biliary colic which tend to exhaust the patient; (2) when there is evidence of inflammation of the gall-bladder; (3) in cases of dropsy of the gall-bladder; and (4) in obstructive jaundice due to the impaction of a calculus in the common duct.

Peritonitis.—I pass by acute general peritonitis as being entirely surgical, and also acute peritonitis occurring as part of an acute miliary tuberculosis. In chronic tuberculous peritonitis there are usually many adhesions, and ascites may be present. The treatment should be medicinal at first, consisting of attention to diet and hygiene, together with cod-liver oil and mercurial inunction to the abdomen. A large percentage of cases are either cured or greatly improved by the performance of laparotomy, which should be undertaken if no progress is made on medical lines. The pathology of the cure is not fully understood. The operation is, of course, useless in cases associated with extensive tuberculous lesions of the lungs or other viscera. Carcinoma of the peritoneum offers very little hope for surgical interference.

Intestines.—In typhoid fever one of the most serious complications is perforation, whether viewed from a medical or surgical point of view. It is most apt to occur in protracted cases, though it may happen as early as the eighth day. I well remember a case in the London Hospital, which perforated some three weeks after the temperature was normal, when the patient was getting up and taking solid food. The chief danger to life is the accompanying peritonitis. It is our duty to give the patient the chance of life afforded by operation, though the mortality is very great. Perforation from tuberculous disease is not a common occurrence, but immediate laparotomy affords the best prospect of cure. Malignant disease of the intestine should come under the surgeon's notice as soon as possible, as by this means the chance of a radical cure is rendered more likely.

Appendicitis.—This disease has, of late years, become more and more a surgical one, and to my mind rightly so. The days of "waiting for an abscess to form" have long since passed. Any treatment is generally hopeless in those terrible fulminating cases in which perforation of a gangrenous appendix occurs without warning. In an ordinary case absolute rest in bed should be enforced, and an ice-bag placed over the region of the appendix. Opium should not be given, or only in small quantities, as it masks the symptoms. Purgatives do more harm than good. One enema may be given, but not repeated. If after forty-eight hours no improvement is manifested, and the temperature and pulse both remain high, together with vomiting, the question of operation should be seriously entertained. If the symptoms are subsiding, operation should be postponed for at any rate a week. Many persons who have had one attack of appendicitis by careful attention to diet and to the state of their teeth may avoid a second, but they are never safe. After the second attack, I think in all cases the appendix should be removed.

FIVE further cases of small-pox—two from Poplar and one each from Bethnal Green, Stepney, and Orsett—have been admitted to the Metropolitan Small-pox hospitals. There are now 44 patients under treatment in London. This state of affairs naturally gives rise to a good deal of anxiety.

A CASE OF ECTOPIC GESTATION NEAR TERM WITH INFECTED OVUM —LAPAROTOMY—RECOVERY.

Under the care of DR. E. GOINARD,
Obstetric Surgeon to the Civil Hospital, Algiers.

[SPECIALLY REPORTED FOR "THE MEDICAL PRESS AND CIRCULAR" BY DR. GUBB.]

I RECENTLY had under my care a young woman, æt. 25, who, on April 20th, was brought to the hospital with symptoms pointing to an acute abdominal lesion. I elicited that her last menstrual period was at the end of January, and beyond the usual symptoms of pregnancy she had observed nothing abnormal until that afternoon when, during the act of micturition, she felt a sharp pain in the hypogastrium, followed by a feeling of faintness which, however, soon passed off.

When I saw her, she was pale, the features drawn, and the lips blanched. The abdomen was distended, painful all over, and the rigidity of the muscles rendered it impossible to obtain any direct information by the aid of palpation. Pulse 150. Temperature normal. No vaginal discharge. On vaginal examination the os was felt to be small and round.

Ice-bags were applied to the abdomen, the bowels emptied by an enema and opium given to relieve the pain. She gradually improved, and two days later I was enabled to make out a globular swelling in the lower part of the belly, reaching three fingers' breadth above the pubes. This was taken to be the gravid uterus. Vaginally some tumefaction was felt in Douglas' pouch, like that associated with an inflamed tube. The improvement continued and, in opposition to my advice, the patient left the hospital on April 30th, eight days after admission.

A week later she returned to the hospital complaining of further abdominal symptoms, but she did not come under my notice, and in view of the obscurity of the symptoms the surgeon on duty performed an exploratory laparotomy. He made a short incision in the middle line and came down upon a globular tumour which looked like the gravid uterus, so he closed the wound, and in dué course the wound healed and the patient was discharged.

She was not seen again until September, when she told us that pregnancy had followed its course with more or less discomfort. She was somewhat emaciated and the lower limbs were extremely œdematous. The urine contained six grammes of albumin per litre. The belly was smaller than one would expect in view of the period of gestation, but the fœtal movements were distinctly felt and the fœtal heart-beat was audible. It was remarked that the uterus lacked the limited mobility usual in the gravid organ. She complained of abdominal pain, recurring in spasms and accompanied by a slight discharge of blood. Labour, however, did not proceed, and the pains ultimately ceased. From this time the fœtal heart beat ceased to be audible, and the mother's plight underwent a marked change for the worse. She became more and more emaciated, the albuminuria persisted, and finally her temperature rose. On vaginal examination the cervix was not obliterated,

and a fulness could be felt in the posterior cul-de-sac.

On October 8th, as a blood count revealed an increase in the proportion of polynuclear corpuscles, I determined to operate. Having obtained anæsthesia by rachis-cocainisation I punctured the posterior cul-de-sac with a fine needle and withdrew pus. I then made a small incision, but without obtaining the evacuation of much fluid, and on introducing my finger I felt the fœtal bones, so that I had evidently opened up the gestation sac. Thereupon, I passed my finger through the cervix, which, though not obliterated, was easily permeable, and found to my surprise that the uterine cavity was empty; in fact, it was evident that we had to do with an ectopic gestation sac.

The patient's condition was most alarming. Her pulse was thready and rapid, and her collapse was such that it hardly seemed possible that she could withstand another operation. However, as it was her only chance, I at once made an incision twenty-five centimetres long in the middle line, through which I withdrew the macerated fœtus. The placenta was removed without occasioning any bleeding. I left the wound open, having packed the cavity with gauze. At this stage we injected artificial serum in considerable quantity.

The subsequent history can be related in a few words. The temperature at once fell to normal, and the sac rapidly closed. The only complication was the formation of a small urinary fistula which soon healed spontaneously, and the patient left the hospital in good health six weeks after the operation. A small sinus still remained, but was rapidly cicatrising.

The interest of the case lies in the difficulty with which the diagnosis was arrived at. Of course, laparotomy is often performed in the treatment of ectopic gestation, but in this instance the central position and general appearance of the cyst, even when exposed by an exploratory laparotomy, led to its being taken for the uterus. Yet it must be admitted that there were certain signs which, looking at the case in the light of our subsequent experience, might have suggested the possibility of the case being one of extra-uterine gestation, such, for instance, as the post-cervical tumefaction. As already explained, the spherical outline and median position of the cyst led us to ignore this indication, so certain did we feel that the tumour felt above the pubes was the gravid uterus. Had we employed the uterine sound much assistance would have been obtained, but I need not insist upon the reluctance with which one has recourse thereto in such cases.

Then, too, when the patient re-entered the hospital for the purpose of delivery, certain signs ought, perhaps, to have put us on our guard—*viz.*, the immobility of the tumour and the resistance of the abdominal walls, but these conditions might conceivably be due to various causes other than extra-uterine pregnancy. I do think, however, that by means of careful bimanual exploration it would have been possible to discover the ovoid body on the right of the tumour which turned out to be the empty uterus. I repeat that what misled us was the steady development of the cyst, exactly in the position normally occupied by the uterus. The case illustrates once again the many difficulties which the diagnosis of extra-uterine pregnancy may present with the result that when present it is often mistaken for some other affection and is not unfrequently diagnosed when non-existent. On the whole I can only congratulate myself on the happy issue of my intervention, though my satisfaction is attenuated by the reflection that, had we operated earlier, we might have saved not only the life of the mother but also that of the infant.

Clinical Records.

PSORIASIS IN CHILDREN.

By G. NORMAN MEACHEN, M.D., B.S., M.R.C.P.,
Physician for Skin Diseases, Tottenham Hospital.

THE influence of age in determining the course, clinical appearances, and other manifestations of disease is by no means the least important or interesting among its etiological factors. With regard to cutaneous disorders, there are very few that are not met with in infancy and childhood, but, like other maladies, certain features may be intensified or suppressed in varying degrees, so that an altogether different picture may be presented in the child from that which is commonly seen in the adult. Psoriasis is a disease which is distinctly rare in infancy, but when it does occur it forms no exception to the general principle of age-modification.

A male infant, æt. 2½, was brought to my out-patient department with the history that the child's body had been covered with spots for two months. The mother stated that she had had "acute rheumatism," for which she was attended by a doctor, and that she had also suffered, as well as her sister, from an exactly similar skin eruption some years ago. On examination,

CASE OF PSORIASIS IN A CHILD, ÆT. 2½.

the whole of the trunk was covered with discrete, nummular patches, typical of psoriasis, the scales being somewhat profuse and easily detached. The photograph shows how loosely they were attached. There were a few spots upon the face and some scaly patches upon the scalp. The eruption was best marked in the dorsal region and front of the chest, the buttocks and groins being less affected, while the lower extremities were perfectly clear. Upon the arms the rash was complicated by a moist eczematous condition, probably secondary in origin. The child's general health was good, with the exception that the bowels were

rather constipated. There did not appear to have been any indiscretion in the dieting. I should mention that the case was kindly sent to me from the medical out-patient department by Dr. G. P. Chappel.

I prescribed the pharmacopœial ung. picis. liq. for application to the spots on the body; the ung. hydrarg. ammon. for the places on the scalp and on the face; a mixture of soda and rhubarb internally, together with a lotion of "cyllin" (formerly known as creolin). A week after this treatment the eruption had nearly disappeared from the trunk, all the scales having vanished. The ammoniated mercury ointment was diluted with the ung. zinci cum plumbi acet. for application to the forearms.

All observers are agreed as to the rarity of psoriasis before the fifth year of life. In a series of 334 cases of the disease collected by Pietro Benassi (*Giorn. ital. d. Mal. Ven. e delle Pelle*, vol. xliv, 1903), of Bologna, only fourteen were met with before the age of ten. The earliest case on record is that of M. Rille (*Journ. des Mal. cutan. et syph.*, vol. xi, 1899), where the affection occurred in an infant, five days old. A few cases have been reported in children from three to eighteen months old. Rille has drawn attention to the fact that psoriasis may occur after vaccination, but, from the readiness with which parents among the hospital out-patient class ascribe cutaneous eruption to the effects of vaccination, too much stress cannot be laid upon this as an exciting factor in the production of the malady. The connection between psoriasis and one or other of the acute exanthemata is sometimes more obvious. The influence of heredity would often appear considerable, and Besnier and Doyen have shown that in the majority of cases of infantile psoriasis a family history of the disease is usually obtainable. In the present case, it will be noticed that the child's mother and aunt had both suffered from it, and in several other instances which I have come across lately of psoriasis in rather older children—*i.e.*, from five to ten—I have not failed to obtain some evidence of the presence of the malady in other members of the family.

The chief characteristics of infantile psoriasis may be stated to be the smaller size of the individual patches, their tendency to a punctate, guttate, or nummular form, the liability to complication by secondary moist eruptions, the easily detached condition of the scales, and the less extensive area of distribution of the lesions. In my case, the gradual diminution of the eruption from the lumbar region downwards was very noticeable, and it was also manifest that the disease affected the flexor surfaces of the trunk and upper limbs quite as much as the extensor. This latter feature is not infrequently observed in adults. A readier response to treatment may be noticed in psoriasis in childhood, but this is also seen in many other kinds of skin diseases, and is probably due to the greater cutaneous reaction to external medication which is met with in the earlier years of life.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXXVI.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

SHERWOOD FOREST SANATORIUM.

In our previous articles we have on several occasions had to draw attention to the advantages of a judicious association of public bodies in establishing and maintaining institutions for the consumptive poor, and we have already described such interesting experimental sanatoria as those of Kelling, at Holt for the tuberculous workers of Norfork, the Westmorland Sanatorium, near Grange. It is only by adequate combination of public or philanthropic supporters that sanatoria for the poor consumptive of our various counties can be efficiently conducted.

An important work for the phthisical of Nottingham and district is being carried out at the Sherwood Forest Sanatorium by the Nottingham and Nottinghamshire Association for the Prevention of Consumption. The objects of this body are defined as:—

"(*a*) To establish in the County of Nottingham a sanatorium for the treatment of consumption in persons of limited means; (*b*) to spread a knowledge of the laws of health, and to encourage voluntary measures tending to reduce the causes of tuberculosis; (*c*) to co-operate in educational and voluntary measures with the National Association for the Prevention of Consumption, and with its local branches." The Association has influential supporters and a committee which is responsible for the conduct of the sanatorium. We were privileged to visit the institution in company with the House Committee and one of the hon. secretaries, Dr. W. B. Ransom, who is also one of the hon. consulting physicians.

The sanatorium is situated on high ground in picturesque country at Ratcher's Hill, in Sherwood Forest. The estate consists of fifty acres of pinewood and heather-covered moorland, and was presented by the Duke of Portland. The site is excellent, the soil is sandy, and pines afford considerable protection and admirable opportunities for enjoyable outdoor life. The elevation is 470 feet above sea-level, and towards the south there is a wide expanse of open country. Mansfield, the nearest town, is about three miles distant and is in telephonic communication with the sanatorium.

The building has been erected by the Portable Buildings Company, of Fleetwood. It is constructed of wood, with double walls placed on a brick foundation. The double walls, with a layer of felt and air-space between, are said to secure warmth in winter and coolness in summer. Long and wide glass-covered verandahs have been constructed on both sides of the wards, thus allowing of a ready and convenient arrangement of the patients so that according to the state of the wind shelter may be obtained and life in the open be fully maintained. The wards are light, clean, and so constructed as not to harbour dirt.

There are several shelters near the main building, and there is at present accommodation for twenty-six patients, thirteen of each sex.

There is a good electric light installation, the dynamo being worked by an oil engine. The building is heated by low pressure hot water, in pipes and radiators. The drainage is on the water system, and the sewage is dealt with in a septic tank. A good supply of water is obtained from the Mansfield Water Works. The construction and equipment of the sanatorium has cost over £5,000. The initial cost per bed is placed at £220. It is estimated that at but slight additional expense provision can be made for an addition of twelve patients.

Treatment is conducted on strict hygienic lines. A lady medical acts as resident medical officer. There is a matron, sister, and probationer and staff of servants. On all hands there is evidence of efficient oversight, judicious economy, and common-sense management. We were glad to find that much local interest and support were forthcoming; there are visiting, house, and after-care committees, all of which appear to be accomplishing much good work.

Two practitioners resident in Mansfield act as hon. visiting medical officers in case of need; and there are four hon. consulting physicians. According to the last medical report available, during the first eleven months of the existence of the sanatorium (which was opened for patients February 3rd, 1902), 61 patients were admitted, 41 were discharged, and of these only 11 were in an early stage, while 21 were classified as serious, and 9 as advanced. Recently encouraging results have been obtained, but hitherto it has not been found possible to find desirable forms of out-door work suited to the physical condition of the patients.

The manner of management presents many features of interest. According to the rules, only those persons are eligible for admission who "(*a*) satisfy the Committee that they are unable to pay for treatment in a

private institution, or to obtain proper treatment at home; (*b*) are certified by one of the consulting physicians to be in such a stage of the disease as to afford reasonable expectation of permanent improvement or cure." Patients must live in the county of Nottinghamshire, or within ten miles of its borders; but preference is given to inhabitants of the county. We understand a number are now on the "waiting list." Much care is taken in the selection of cases, many being first kept under observation by the examining physician in the Nottingham General Hospital. Patients are admitted to the sanatorium "(*a*) on the nomination of persons or groups of persons called nominators, who pay the cost of maintenance of a bed and have the right of nominating to that bed, subject to the by-laws drawn up by the Committee; (*b*) on the recommendation of members of the Association; (*c*) the Committee shall have power to enter into any agreement with any local authority for the reception of sick inhabitants of the district of such authority (subject to these rules and to any by-laws made by the Committee) on payment of such annual or other sum as may be agreed upon." Persons or groups of persons subscribing £75 annually have the right of nomination to a Free Bed for one year. A subscription of £40 annually gives a nomination for six months, and £20 for three months. Persons or groups of persons may also become Nominators to a bed for which the patient pays ten shillings a week on the following terms:—"50 guineas for one year; 26 guineas for six months; and 13 guineas for three months. If, however, all the beds are not allotted to nominators and the income of the Association permits, persons may be admitted on the recommendation of a member to a free bed, to a partly free bed, or to a paying bed, where the patient pays the whole cost of his maintenance (31s. a week)."

The Notts Consumption Sanatorium is worthy of careful study by all county authorities, public bodies, and combinations of benevolent persons anxious to alleviate the lot of the phthisical sufferer and lessen the prevalence of human tuberculosis. It affords an excellent example of good work accomplished in the face of considerable difficulties and at almost a minimum of expenditure.

Continental Health Resorts.

RIVIERA NOTES—CANNES.

[FROM OUR SPECIAL CORRESPONDENT.]

YEARS ago our British people came to the Côte d'Azur for rest and for health. Now, the Riviera seems chiefly sought for pleasure. Each year the "season" here grows shorter; visitors come later and go away earlier. Even the most comfortable trains begin in what, not long ago, would have been considered the middle of the season, and are taken off before what are really the most agreeable months on the Riviera.

For those busy bread-winners and active politicians who cannot spare a longer play-time, this brief breathing spell is better than none; but for those who have leisure, and especially for those who are invalid, delicate, or need rest and a climatic change, the old custom of coming in October or November, and remaining along the Mediterranean Coast until May, was decidedly the better and safer course. To derive benefit from a climatic change, it is well to get acclimatised *before winter commences;* better still, not to whirl away from a southern climate abruptly, before May has ameliorated our insular weather.

Years ago likewise, medical writers dwelt much on the climatic differences, and these are, of a truth, more noticeable between not only the different resorts on the Riviera, but also of the really diverse "zones" at each of the principal Riviera resorts. Comparisons and statistics abounded in medical articles and books formerly. Now, so many thousands of our people come abroad that everyone is supposed to know all that is necessary about Continental places.

This idea of the superiority of present day knowledge is a fallacy, as is nowhere more apparent than on the Riviera. All along the coast one meets families in hotels and villas located precisely where one or more of the members ought not to be even for a limited visit. It would have been better for their health had they stayed away. If one asks why they selected that particular place, the reply is, "Somebody said to them 'go to the Riviera,' or others recommended such and such hotels." It is old adage, "One man's meat is another man's poison." So on the Riviera, some towns suit certain constitutions and benefit some individual or transient states of health which would not suit, and might even be detrimental to, other peculiarities and constitutions. In the same towns even different localities vary noticeably. Continental physicians seem to be, at present, studying these phases of the question more actively than our own medical writers. The "Index Médical," recently published by the Syndicat Général des Médecins des Stations Balnéaires et Sanitaires de France, gives an admirable *résumé* of the climatic and other advantages of Cannes, and of the indications for its different residential zones, relative to particular cases, needs, and constitutions.

Medically considered, Cannes includes the large territory, formerly the great valley of the Liagne river, embraced between Cap Roux of the Esterel range on the west, and on the east by the spurs of the Alpes Maritimes, terminating at the Croisette. This territory of triangular shape, the town of Cannes lying at its southern base, and the town of Grasse at its northern point, is well shielded by heights, especially from north and west winds—*i.e.*, from mistrals by mountains, and by wooded hills from undesirable easterly winds coming across the Gulf of Genoa and from the snow peaks of Northern Italy. It lies open to southern winds and sea-breezes. It is broken up in the interior of the plain and in Cannes itself by a variety of small hills, the chains of which run chiefly north and south, affording many sites more or less elevated. These sites are much varied, some on summits, some in glades, others on hill-sides amid woods and flowers. Sheltered or in open spaces, shaded by trees, or in full sunlight; near the sea or inland; in spacious vivifying atmosphere, or in calm and sedative seclusion; in all kinds of positions are residences, elegant or modest, suitable for a variety of purses and of preferences. In this lies the great charm of Cannes, as compared with less varied and less favoured seashore resorts. Owing to the convenient elevations on which in large gardens are many picturesquely situated villas and hotels, as the Hôtel Continental on a rock yet only five minutes from the central sea-side square, visitors can very agreeably remain at Cannes throughout April and May; and at the neighbouring town of Grasse (1,100 feet altitude) even until midsummer. The numerous easy excursions around Cannes and Grasse, among hills, woods, and vales rich in flora, mediæval villages, prehistoric vestiges, and grand scenery, make the months of April, May, and early June the most pleasant here of the year.

Those who do not wish to travel long distances, yet desire to derive all the benefits of summer at an Alpine altitude, would find at the Grand Hôtel Climaterique of Thorens (three hours' drive from Grasse railway station), a very desirable summer-home, over 4,000 feet above ocean-level, amidst vast forests and great hills, and in every respect most comfortable. The high valley of Thorens consists of about 12,000 acres of park-like ground, broken up by woods and rock terraces, the views extending from snow-covered Alps to the Mediterranean; and its mountain atmosphere, tempered by pine forests, is delicious and fortifying.

Transactions of Societies.

HARVEIAN SOCIETY OF LONDON.

CLINICAL MEETING AT ST. MARY'S HOSPITAL, FEBRUARY 25TH, 1904.

DR. D. B. LEES showed a case of

APHASIA WITH ANOMALOUS SYMPTOMS,

also a case illustrating the use of large doses of sodium

salicylate. This patient had taken at irregular periods as much as 400 grains of sodium salicylate in combination with potass. bicarbonate per diem, and if the drug was discontinued symptoms immediately recurred. This case exhibited well the great tolerance patients had or soon acquired for sodium salicylate.

Dr. PHILLIPS remarked that he never used such heroic doses of sodium salicylate, but in these cases preferred to try aspirin.

Dr. WM. HILL inquired the cause of absence of tinnitus when administering these large doses of sodium salicylate. Was it due to the combination with potass. bicarbonate?

The PRESIDENT inquired of the cause of aphasia in the first case—*i.e.*, what was its pathology in this instance? In the second case, was she to continue the salicylate for ever?

Dr. LEES said salicylate in large doses was really stimulating, and we were discouraged when ear symptoms appeared, and immediately discontinued the drug. The pathology of tinnitus was probably that of partial cerebral thrombosis.

Dr. SIDNEY PHILLIPS showed a case of

OSTEO-ARTHRITIS OF THE SPINE,

in which there was thickening, pain, tenderness, partial fixation by spasm and rigidity over the upper four dorsal spines. The head was slightly flexed to the left and rotated at an angle to the vertebræ. The deltoid, pectorals, and triceps on the one side were wasted, and there was deformity of the fingers, with glossy skin and tingling of the same hand, suggesting pressure on the nerves in the inter-vertebral foramina. Dr. Phillips thought these cases much more common than is usually assumed

Mr. LOCKHART MUMMERY considered the case to be one of those called spondylitis deformans.

Mr. SILCOCK considered it the type of disease found in workers in the open air, and was very ancient, being found in Roman bones.

Dr. PHILLIPS did not consider it to be one of the ordinary type referred to, but it seemed to him to be a case of pure osteo-arthritis of the spinal articulations.

Dr. CALEY showed a case of

RAYNAUD'S DISEASE WITH SPLENOMEGALY.

Dr. E. CAUTLEY asked Dr. Caley if the splenic notch was in a normal condition, that is, was the growth symmetrical? He had seen a case with twisting of the pedicle in which the organ enlarged, then subsided, but left some permanent enlargement. This case might be of the same nature.

Dr. CALEY thought the axis normal, and notch proportionately normal, but was too tender to examine carefully. Against twisting of the pedicle was the fact that symptoms came on when the patient was at rest.

The PRESIDENT commented on the case.

Mr. A. Q. SILCOCK showed a woman, æt. 30, who had been the subject of a dermoid cyst of right side of chest. She was admitted to St. Mary's under Dr. Lees, in February, 1903, presumably suffering from empyema, which was opened and found to contain a large quantity of caseating sebaceous material mixed with pus. Subsequent examination proved the (?) empyema to be a suppurating dermoid cyst. Portions of the cyst wall were removed at intervals, the patient being too weak to stand prolonged operations. As a result, the cavity became smaller and the suppuration diminished. Finally the whole of the remaining cyst wall was dissected away. Mr. Silcock remarked upon the infrequency of the affection, and upon the fact that many of the reported cases had been mistaken for empyema. The cyst was about the size of a polo ball or larger. He had as yet been unable to find a case in which a cyst of this size had been extirpated, and pointed out the difficulties of so doing, especially in separating it from the pericardium.

Dr. LEES considered the case practically unique. When admitted he thought it to be a pleuritis; there was slight pain in the side, with cough; the heart was pushed far into the left axilla, a point against pleurisy, but which may be present in hydatid of the lung or liver. The case was difficult to examine.

Mr. CLAYTON GREENE showed a case of hernia cerebri following a compound depressed fracture of the skull. The patient, a girl, æt. 10, fell out of a window into an area on October 26th, and was admitted under Mr. Silcock. In spite of local treatment the brain protrusion increased, a leaden plate was applied without benefit, absolute alcohol was beneficial, but did not check the hernia cerebri, carbolic acid was useless. About a month after admission a mass of hernia cerebri the size of an orange was excised; free hæmorrhage resulted, which adrenalin failed to check.

The hernia gradually re-formed and surpassed its original size. Everything failing to remedy this condition, it was again removed, this time by means of an electric snare. It was followed by little bleeding and no shock. Extensive œdema of eyelids, face and neck appeared, but gradually subsided. Three points of interest were remarked upon. (1) The hernia consisted largely of brain matter, not granulation tissue. (2) All treatment short of removing the protrusion was ineffectual. (3) In spite of abscision of a large portion of the frontal lobe, there was no loss of intelligence, or moral perversion, as far as could be judged. The facial paralysis was rapidly improving.

Mr. SILCOCK considered the condition due to extension of the suppuration into the cranial cavity, and regretted he did not open up and remove bone more freely in the first instance.

Mr. P. L. DANIEL showed a case of a young woman, æt. 24, who, immediately after delivery of a second child nineteen months ago, was seized with small-pox. Seven weeks later, when she returned from hospital, she noticed a small tumour on the right side of thorax. Mr. Daniel considered the case to be cutaneous actinomycosis associated with visceral involvement, a condition which in recent years was shown to be not uncommon, and was considered to be syphilitic because it cleared up under potassium iodide.

Mr. JAFFRAY referred to two cases of a somewhat similar nature, which he had first treated as gummata, which did not break down, but cleared up under potassium iodide.

Dr. GRAHAM LITTLE showed an interesting case of lupus associated with lichen scrophulosorum. An injection of tuberculin (No. 1) resulted in a typical reaction, in which the lichen scrophulosorum participated, becoming vividly red. The reaction of the lichen scrophulosorum, and its association with a definite tuberculous lesion, was interesting. He exhibited drawings of the condition.

Dr. NICHOLSON (for Dr. Cheadle) showed a case of (?) primary malignant disease of the liver, with microscope specimens.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, FEBRUARY 18TH, 1904.

JAMES BARR, M.D., F.R.C.P., President, in the Chair.

PERFORATING ULCER OF THE STOMACH.

DR. BUCHANAN and Mr. W. THELWALL THOMAS related a case in which an operation had been successfully performed for perforated gastric ulcer. The patient was an anæmic girl who was suddenly seized with acute abdominal pain, for which she was admitted into hospital. The diagnosis was at first doubtful, the continued elevation of temperature and a marked leucocytosis suggested the possibility of typhoid fever. The subsequent progress of the case, however, revealed a localised peritonitis, which was thought to be most probably due to a perforated gastric ulcer. On the twelfth day of the illness Mr. Thelwall Thomas operated. The stomach and the liver were adherent to the abdominal wall, and on separating these adhesions a localised abscess was opened and a distinct hole seen in the stomach. An unsuccessful attempt was made to close the perforation with stitches, and finally the abdominal wound was left open and packed with gauze. Convalescence was prolonged, but the patient ultimately made a satisfactory recovery.

PERFORATING ULCER OF THE DUODENUM.

Mr. DAMER HARRISSON related a case in which he had successfully operated upon a man, æt. 45, for perforating ulcer of the duodenum. There had been no previous gastric symptoms. The patient was suddenly seized with acute abdominal pain, which he referred more especially to the right iliac fossa. An operation was performed eleven and a half hours after the onset. A perforated ulcer of the duodenum, close to the pylorus, was found and closed with sutures.

Mr. LITTLER JONES referred to a case in which perforation of a gastric ulcer had occurred at midnight. The patient finding that the pain was relieved by the knee-elbow position, remained in that posture all night. At the operation next day, there was found an anterior perforation of the stomach, with little if any extravasation, but fair adhesions.

Dr. E. T. Davies, Mr. Newbolt, Mr. George Hamilton, Dr. Carter, and Dr. Macalister took part in the discussion on these cases.

THE TREATMENT OF MALARIAL FEVER.

Dr. CARTER read a note on the treatment of some cases of malarial fever. Four cases had come under his care during 1903; they all, more or less, resembled each other. They were cases of obstinate continuance of fever, in spite of all the ordinary remedies; there was complete breakdown of the general health, and loss of weight. In every instance, a complete and apparently permanent relief of all symptoms had followed upon the administration of Warburg's tincture. In one case the patient had suffered from frequent attacks of malarial fever during the last three years, and during the last attack, in spite of the administration of large doses of quinine, the temperature rose to 106° F., but after a few doses of Warburg's tincture the temperature fell to normal, the general health markedly improved, and apparently permanent relief has followed.

Dr. BRIGGS read a paper on the

TREATMENT OF SEVERE CASES OF PLACENTA PRÆVIA.

By severe cases were understood one considerable, or two or more recurrences of, hæmorrhage, regardless of the degree of placenta prævia. The paper was mainly based upon the more modern means of treatment, which promises to improve the results obtainable in the management of these cases. Dr. Briggs first alluded to the bag devised by Champetier de Ribes, which, together with its forceps, presents an inconvenient and cumbrous appearance, hence, possibly, the comparative rarity of the use of the bag in the treatment of severe cases of placenta prævia. Its use could be rendered easy by preliminary dilatation of the cervix, by the finger or by Bossi's method in the rare instances in which the latter is required. The twenty-two cases tabulated, and the conclusions formulated in the paper by Dr. Blacker, in the Obstetrical Society's "Transactions" for 1897, were freely used by Dr. Briggs. Blacker quotes the words of Champetier de Ribes:—"I should be disposed in a case of placenta prævia, with no pains, to rupture the membranes when I was able to reach them, and to place the bag within the amniotic cavity. I am convinced that the bag would form an excellent tampon, fulfilling all the conditions necessary in these grave cases to ensure the best result to the mother and to the child." Dr. Briggs cited two severe cases of placenta prævia, as illustrating the value of the treatment he advocated—(1) in the twenty-eighth week of gestation, when the cervix was closed, the bleeding was free and labour pains absent; and (2) a full-term labour with copious hæmorrhage. In both the bag was used, and in the former preliminary dilatation was effected by Bossi's instrument, which enabled the medical attendants to complete what had been a presumptive diagnosis, and to introduce the bag of Champetier de Ribes, which served its purpose by controlling the bleeding, inciting and completing labour in eight hours. In the second case, labour had commenced and was completed with a living child in the first vertex position, in two and a half hours after the bag had been introduced. Dr. Briggs then referred to De Paoli's nineteen cases of placenta prævia treated by Bossi's method, completed in five to twenty-five minutes, without laceration of the cervix, and with a death-rate of one mother and three children. Dr. Briggs expressed his opinion that rapid delivery in cases of placenta prævia was becoming a more common practice. He cited his own experience in six cases in which for grave internal conditions he had used Bossi's method. As to the use of the bag, its great value consisted in its easy introduction, its standing boiling, and its perfect control of the bleeding, forming, as Dr. Herman had stated, a better hæmostatic wedge than the half-breech of the child, after turning. From his own experience of thirty cases treated by version, he concluded that forcible delivery was rarely necessary, for in all these cases the bleeding had been controlled, and without exception, traction on the child was not required to check bleeding. It was probable that in many cases hæmorrhage from laceration of the cervix during podalic version was a source of bleeding, due to the treatment adopted. The interests of the child were improved by the use of the bag of Champetier, and whenever the bag was available it ought to be used in the treatment of placenta prævia.

Dr. JOHN GEMMELL said that most cases of placenta prævia were of the marginal type, and in these the use of the bag was not necessary. Further, the introduction of the bag necessitated the presence of a second medical attendant to administer an anæsthetic, which would render its being generally employed impracticable.

Dr. LLEWELLYN MORGAN relied upon tight packing as a routine treatment in cases of severe hæmorrhage.

Drs. Heatherley, E. T. Davies, Mackay, Blair Bell, and Littlejohn also took part in the discussion, and Dr. BRIGGS replied.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

A MEETING of this Society was held on FEBRUARY 19TH, 1904, at 11 Chandos Street, Cavendish Square, W., Mr. R. CLEMENT LUCAS in the chair.

A case of cerebral diplegia with changes in the fundus oculi was shown by Dr. ROBERT HUTCHINSON. The child was æt. 17 months. It was full time, the labour was easy, and there was no history of syphilis. All its limbs were flexed on the trunk, the muscles were spastic and the deep reflexes were exaggerated. It was imbecile. The optic discs were atrophic, there was extensive choroido-retinitis and diffuse opacities in the lenses. The condition was thought to be due to arrested development of the cortex cerebri, probably syphilitic.

A case of progressive cerebral degeneration of the family type was also shown by Dr. Hutchinson. A boy, æt. 4, was healthy until æt. 10 months, when fits occurred on and off for some weeks. Two months ago he began to stagger when walking, and he next developed some spasticity of the legs with mental apathy. The optic discs were becoming atrophic. There was another child in the family who became affected in the same way and at the same age. There was no history of syphilis.

Mr. SYDNEY STEPHENSON thought the case belonged to a group which had been more or less worked out lately, one in which systemic symptoms were those of cerebral degeneration, which were correlated with fundus changes, the optic discs being pale, but not necessarily atrophic. Smallness of the retinal vessels was also noticed, and fine pigmentary changes in the central region of the fundus. He had seen one case the offspring of a consanguineous marriage.

Mr. JACKSON CLARKE thought the cases illustrated the importance of consultation with a physician before surgical treatment was undertaken in young children with general spasticity.

A case of symmetrical bilateral branchial fistulæ with symmetrical bilateral helical fistulæ and misshapen aural pinnæ was shown by Mr. J. HOWELL EVANS. In the cases recorded by Sir James Paget there was a very definite hereditary influence. There were other congenital deformities in members of the family in Mr. Evans' case.

Mr. MUMMERY did not agree with Mr. Evans that the

fistulæ in the case were in the position of the fourth branchial cleft; he thought it was the third.

Mr. CLEMENT LUCAS said the cases showed the extreme hereditary tendency there was. He had seen closed fistulæ mistaken for glands in the neck owing to cyst formation.

Mr. EVANS, in reply, said it was the third cleft as usually reckoned, but he was inclined to view it differently.

A portion of a coin catcher which had been removed by gastrotomy was shown by Mr. DONALD ARMOUR.

A case of vertical monocular nystagmus was shown by Mr. ARNOLD LAWSON.

An early case of Friedreich's disease was shown by Mr. JACKSON CLARKE.

A specimen of secondary angio-sarcoma of the lung was shown by Dr. W. A. WILLS and Mr. DOUGLAS DREW. Mr. Drew removed the left testicle for sarcoma in April, 1903, and there was no recurrence, local or general, until December, 1903. It was thought to be a case of empyema when admitted, and a rib was resected so sanguine were they that there was pus, but at the resection a new growth was discovered. At the post-mortem it was thought to be a primary sarcoma of the lung, but subsequent inquiries negatived that idea, and the case illustrated how a fallacy might arise even after a very careful post-mortem examination. Mr. Douglas Drew reminded the Society that in the previous November he had exhibited the child as one of cure after removal of sarcoma of the testicle. On the last occasion he had seen the child, Dr. Parkinson had found no evidence of disease in the lungs. The primary growth was adeno-myxo-sarcoma. The lung tumour resembled the primary growth in part, but the rest of it was of the nature of angio-sarcoma or endothelioma.

Dr. PARKINSON thought that the growth started at the root of the lung, that it came to the surface comparatively late and that was why there were not any physical signs.

Dr. WILLS, in reply, thought the growth had been extremely rapid at the last.

A case of anæsthesia and recurrent ulceration of the gluteal regions from spina bifida was shown by Dr. PARKES WEBER.

Microscopic sections of the kidney from a case of general œdema in an infant were shown by Dr. GEORGE CARPENTER. The infant was breast-fed. It was dropsical like a case of nephritis, and there was albuminuria, but no tube casts. Post-mortem, there were no inflammatory renal changes, but the kidneys could not be looked upon as absolutely normal in that they showed exudation between the glomeruli and their capsules and in the convoluted tubules, but there was complete absence of catarrhal or interstitial changes. He considered the condition toxæmic, but the nature of the toxin was not obvious or, indeed, the cause for death.

Dr. PARKES WEBER thought the case was an example of what could be called toxæmic œdema and toxæmic albuminuria. Absence of nephritis in such cases might be due to personal peculiarity. Microscopic sections of the heart and kidney from a case of acute œdema of the lungs and sudden death were shown by Dr. GEORGE CARPENTER. The child came under observation clinically as a case of heart failure, and it was diagnosed during life as one of uncomplicated myocarditis. The urine was loaded with albumin, there were no patellar reflexes and the soft palate was thought not to move freely. There was no history of diphtheria, but taking the clinical findings into consideration the condition was thought to be diphtheritic. Dr. Carpenter drew attention to his observations on uncomplicated myocarditis in children during the previous session and recorded in the Reports of the Society, and published in the *Lancet* in 1903, and said that the case well illustrated the clinical conditions met with in those cases which were diphtheritic and rheumatic. The child died suddenly the following day. The heart muscle showed well-marked degenerative changes. Contrary to the finding in one of his published cases, there were no interstitial changes in the present instance, and the condition was not inflammatory. He thought observations should more frequently be directed to the microscopical examination of the cardiac muscle in all diseases than happened at present. Clinically in his experience cases of weak cardiac action and probably of toxæmic origin were not uncommon, and he thought that such cases as he had called attention to would be more frequently discovered if looked for.

Dr. HUTCHINSON said he agreed with Dr. Carpenter's view that the condition of the heart was due to the diphtheritic poison.

Dr. C. O. HAWTHORNE was disposed to agree with Dr. Carpenter. Cases of sudden syncope after diphtheria were, of course, well known. Dr. Carpenter's case, in all probability, afforded a demonstration of the manner in which these disasters were produced.

Dr. C. W. CHAPMAN narrated a case of post-diphtheritic rapid cardiac dilatation with syncope.

Dr. PARKES WEBER thought that Dr. Carpenter had hit upon the only possible explanation.

Mr. CLEMENT LUCAS thought the case showed that the condition might easily be overlooked. He called attention to an epidemic of slight sore throats in a surgical ward where the diphtheria bacillus was found in swabs taken from these throats, but the patients had no serious symptoms.

Dr. CARPENTER, in reply, said a girl, æt. 6, under his care for cardiac failure, with a systolic apex bruit, a dilated heart, and a pulsating liver and albuminuria completely recovered in due course and before she developed paralysis of the soft palate nearly a month after she was first seen, which thus clearly demonstrated the nature of the toxæmia, though at the time the cause of the heart failure was not obvious.

A paper on the treatment of hernia in young children was read by Mr. LOCKHART MUMMERY.

Mr. CLEMENT LUCAS alluded to the special difficulty in young children, that of isolating the vas deferens from the sac. There was a real danger of destruction in inexperienced hands.

Mr. MUMMERY, in reply, said it was precisely that difficulty referred to by Mr. Lucas to which he alluded.

The organs from a case of hemi-hypertrophy were shown by Dr. ROBERT HUTCHINSON. He was a healthy, well-developed child with three small capillary nævi in the skin. The left arm and leg were hypertrophied, and to some extent the trunk also. The asymmetry of the limbs was apparently due to an increase of the subcutaneous tissues of the left side, resembling a diffuse lipoma. He subsequently developed an empyema and died. The increased thickness of the lett limbs was entirely owing to an increased deposit of subcutaneous fat. The bones were normal. Most of the paired organs were decidedly larger on the left side than on the right. The left lobe of the thymus was larger, but the two lobes of the thyroid were symmetrical. The liver contained some multiple angiomata. He thought the condition must date back to embryonic life and be in consequence of unequal segmentation in the ovum.

Dr. HAWTHORNE alluded to a case of Dr. MacGregor's, of Glasgow, where the hypertrophy was limited to the lower limb. Post-mortem, there was a tumour of the optic thalamus. In view of the relation between the enlargement of the pituitary body and the condition of acromegaly, Dr. MacGregor's case seemed of much importance.

Dr. PARKES WEBER said the case furnished an excellent example of the association of congenital general overgrowth of a portion of the body with angiomata in the skin representing vascular overgrowth.

Dr. HUTCHINSON, in reply, showed a giant finger which had been amputated and also an enlarged suprarenal capsule on the same side from the same patient.

NORTH-EAST LONDON CLINICAL SOCIETY.

MEETING HELD THURSDAY, MARCH 3RD, 1904.

DR. J. W. HUNT, President, in the Chair.

DR. G. P. CHAPPEL read a paper on some of the LIMITATIONS OF MEDICINE IN ABDOMINAL DISEASE, an abstract of which will be found on page 254.

Dr. FREDERICK H. DALY remarked upon the great

advances which antiseptic surgery had made, whereby it was possible to operate successfully upon cases of gall-stones, and he referred to a paper which he had read upon the subject twenty-five years ago before the Clinical Society of London, when such an operation as cholecystotomy was deprecated by nearly all present.

Dr. E. HOOPER MAY expressed the opinion that cases were invariably sent into hospitals too late, and pleaded for the earlier assistance of the surgeon. He considered that those cases of perforated gastric ulcer in which there was a history of profuse hæmorrhage often did better than those in which this symptom was only slightly marked.

Dr. R. MURRAY LESLIE agreed that much hæmatemesis was seldom a feature of the cases which went on to perforation. The reason why the hæmorrhagic cases recovered sooner was probably because the physician was thus placed earlier upon his guard, and a rigid diet was at once enforced.

Dr. THOMAS RUSHBROOKE said that there were many cases of appendicitis in which it took longer than twelve hours to decide the diagnosis. He thought that if the consulting surgeon realised the great difficulties which beset the general practitioner in respect to the question of operative interference he would sympathise more with him.

Mr. WALTER EDMUNDS referred to the difficulty of diagnosis caused by the presence of a pancreatic cyst, and said that surgical aid had been of value in certain cases of spasmodic contraction of the pylorus in children.

Mr. HERBERT W. CARSON considered that abdominal troubles might be divided into two groups, those which were primarily surgical, and those which secondarily became so. In the first class he would include all acute perforative lesions and all cases of appendicitis. To the second class he referred all cases of chronic gastric disorders accompanied by perigastric adhesions. He drew attention to the prospect held out of the cure or alleviation of cirrhosis of the liver by surgical measures, and to the importance of more frequent examination of the blood for leucocytosis as an index of suppurative changes.

The PRESIDENT thought that the moral effect upon the patient's mind of a proposal to operate must be taken into consideration, and that, while an exploratory incision was of the greatest value in all doubtful cases, it was as well that the public should be disabused of the idea that a surgeon, when called in, would of necessity operate in all cases.

Dr. CHAPPEL replied.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 6th, 1904.

INTESTINAL EXPERIMENT.

KREIDL showed a dog to the members of the Gesellschaft der Aerzte, on which he had operated fourteen days previously by stripping off the muscular covering of the small intestine over a metre of its length. The day after the operation the dog was quite fresh and took its food as the other dogs. The stools were regular and natural without any abnormal appearances. He concluded that muscularis mucosa was quite sufficient, as it had proved in this case, to carry on the continuity of the bowels without the support of the muscular covering of the canal.

VESICULAR DIVERTICULUM.

KÖLLES exhibited a young man, æt. 17, with a diverticulum in the bladder which could be felt and seen as a firm tumour in the right lower part of the abdomen. Its size varied from that of an apple to a man's fist. The cystoscope revealed two funnel-shaped openings in the wall of the bladder from which urine could be pressed. The Röntgen rays confirmed the pouch, which could be emptied and blown up as a tumour. The bladder, when full, would contain two litres, while the residue or sac would give out 850 cubic centimetres when pressed empty.

PERFORATION OF THE PROCESS VERMIFORMIS.

Moszkowicz brought forward a girl, æt. 8, who in her fifth year had a perforation of the vermiform process, followed by two abscesses, one in the right and one in the left iliac fossæ, which were opened as soon as they were discovered. Five weeks later an operation had to be performed for a stenosis of the bowel, owing to some backing of the ileo-omentum, when an artificial anus was made in the upper part of the ileum. After this time she rapidly gained in weight, rising from sixteen to twenty-one kilos in a very short space of time.

A fistula formed later within the rectum that admitted of the closure of the artificial anus.

The saving of this child he attributed to the early opening of the two abscesses, which were not in communication.

PURULENT PERITYPHLITIS.

This is a subject that had been opened for discussion by Moszkowicz at a former meeting.

Schnitzler said that he had operated on seventy-two cases for pus in connection with the appendix, with the death-rate of 14 per cent.

This form of abscess should be operated on as soon as it has been diagnosed that matter is present; when it occurs in the pouch of Douglas, the rectal operation is the best. When meteorism is present the danger of infection in the peritoneum is very great. He thinks it very bad practice to go searching through the abdomen for hypothetical abscesses after opening the primary one. He is, however, a strong advocate of early opening. Whatever has to be done in the way of operating should be done within the first twenty-four or forty-eight hours, whenever diagnosed.

Spieler preferred the radical operation at once. If the appendicitis be the real cause why not remove the appendix in the first place, and more particularly in children where the diffuse form is more common, and which form two-thirds of the whole number? He thought there was no more danger in the radical operation than in the expectant one of opening an abscess. It is noteworthy that the peritoneum loses its power of absorption after inflammations, such as that of the vermiform process, and becomes very inactive, probably owing to the changes in the endothelium, which may have the power of destroying the function of the membrane.

Toges related the history of a few cases that had come under his own observation, where certain inflammatory processes of the female genitals had produced purulent perityphlitis. These often result in purulent inflammation of the adnexa, with subsequent bands of adhesion.

Lotheissen said that he invariably incised the perityphlitic abscesses where it was at all possible, over the appendix in the cæcal region. He is also in favour of early action, even though there be no fever but a quick pulse and fluid in the right flank. The prognosis is always better in the single abscess than in the multilocular. The prognosis of a general peritonitis accompanying the abscess will depend upon the nature of the exudation, the cause of the abscess and the resisting power of the patient, such as age and temperament.

He related the history of twelve cases of purulent peritonitis he had operated on when collapse had set in and the patients were almost pulseless. Yet only three were saved out of the twelve. If he were to offer any advice on the subject, he would say, operate within the first four days of the illness, by performing laparotomy and draining thoroughly.

Ullmann thought that the purulent ichorous peritonitis is usually the consequence of the bursting of

the abscess and not the opposite as Moszkowicz had affirmed. He condemned the further search for other abscesses after opening the primary, and thought it impossible to diagnose multiple abscesses. It was better to wait with confidence and hope after incising the primary abscess.

Owing to the absence of a precise clinical diagnosis the whole question was a difficult one to offer an opinion on. As to operating early with success he entertained grave doubts on this point and was glad to see that Gersuny shared this opinion. He had operated early in many cases, perhaps too early, where the disease had the appearance of a simple abscess, but to his disappointment they had turned out to be the most severe cases he had had. There was danger also in being too early.

Hochenegg announced himself as an advocate of early operation and admonished all his colleagues to operate as soon as they had made a correct diagnosis. It is difficult to forecast from any diagnosis we can make what will be a light case or a severe case. He had recently operated on twelve cases in the early stage, and not one of them died. In the same time he had operated on twenty-nine cases, with diffuse peritonitis, and twenty-seven of them died! There was no doubt that a single abscess would be a favourable case and would recover in a short time, while a multilocular form would be protracted.

The best method of opening an abscess in the pouch of Douglas is by the para-sacral operation. What he understood by a Douglas abscess was one quite closed up in that sac of the peritoneum having no connection with the appendix. The radical operation is not always so simple as described, as not infrequently we meet with a number of capsuled abscesses around the appendix, filled with pus that may or may not be removed, but as a rule the interval operation is the more successful.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

Tuberculous Disease of Elbow-Joint.—Erasion of the Elbow-Joint.—Mr. Mayo Collier operated on a boy with extensive disease of the left elbow-joint. He said the boy was admitted under his care for operation, but previous to this he had been treated for prolonged periods with immobility secured by splints, and general attention to health. Some improvement had taken place so long as the elbow was kept fixed, but as soon as functional activity was allowed the trouble set up with increased vigour. The present condition was not favourable for operation, and a useful joint was a matter of considerable doubt. The disease had invaded the whole lining membrane of the joint and had extended in various directions. There was a large abscess extending from the outer condyle halfway down the radius, and a similar boggy condition of the tissues over the lower third of the humerus. There was distinct grating in the radio-humeral and ulna-humeral joints. The question was, What form of operation would be most advisable? Excision was out of the question, as by this procedure it would be impossible to get beyond the disease. The treatment lay between amputation and erasion, and seeing that the boy was in other respects apparently free from disease, Mr. Collier decided to do an erasion of the joint and scrape and curette all the abscess cavities and tracts, and, if possible, secure a fair joint. At all events, the more severe operation of amputation could always be resorted to if the present procedure failed to remove the disease. Mr. Collier made an incision over the upper third of the radius and opened a large cavity filled with tuberculous granulations and *débris*, exposing the upper third of the radius in a bare and carious condition. The elbow-joint was further opened by a transverse incision over the back of the joint, opening a second large collection of tuberculous granulations and *débris*. The olecranon was next sawn through transversely, and the cavity of the joint being now freely exposed, the operator set to work with scissors, curette, and forceps to remove the whole of the tuberculous synovial membrane and diseased structures. This procedure occupied a considerable time. The upper third of the radius was removed, and the whole cavity deluged with hot carbolic lotion. The bleeding being arrested, the tracts and hollows were packed with strips of gauze soaked in iodoform emulsion. A drain was left in opposite each condyle, and the limb supported on a rectangular splint. Mr. Collier said this elbow was an excellent example of the harm that may result in trusting too long to rest and splints. In the very earliest stages this was good treatment, but so soon as definite thickening and granulation had occurred nothing but erasion or excision could be of the smallest use. In this case, the disease had got beyond the joint and invaded the tissue of the forearm, and it was perhaps too much to expect that the procedure now adopted would result in a useful limb. However, Mr. Collier thought it right to give the boy the chance.

FRENCH HOSPITAL AND DISPENSARY.

Resection of Ribs.—Mr. Clayton Greene operated on a patient, æt. 21, who had been admitted four months ago for a large swelling (fluid) over the ribs and sternum of the shape of an inverted pear, pulsating with the heart-beats, and which had gradually been increasing in size for the past three months. There was a history of a blow received about four months before the man's admission, and also a history of influenza. On examination, the swelling was found to be fluctuant, not reducible, and was evidently an abscess. On inserting an exploring needle, purulent material was withdrawn. The swelling was incised and about a pint and a half of pus was let out. On further examination it was found that the second rib and the posterior part of the sternum were carious, and the lung was flattened on to the posterior chest wall. The second rib was removed and a large empyema tube was inserted. About three months afterwards the patient was sent to the Brighton Convalescent Home with a small discharging sinus. A month afterwards he was readmitted to the hospital with a small fluctuating mass over his sternum. This was incised and scraped, and was found to communicate with the old sinus, and on further exploration the first rib was also found to be carious. This rib was then removed after very careful separation of the structures in the immediate vicinity; the old sinus was well scraped out; new bone was found to have been formed where the second rib had been removed; the lung, too, had expanded. The incision for the excision of the first rib was completely sewn up, and a large drainage-tube then inserted up to the first rib cartilage, together with gauze plugging, which was to be removed in twenty-four hours. The wound healed by first intention, and the patient is doing very well indeed. Remarks by Mr. Greene on this case will be published next week in "Operating Theatres."

The following telegram from the officer administering the Government of Mauritius was received at the Colonial Office on the 4th inst.:—"For the week ending March 3rd, six cases of plague, five fatal."

"SALUS POPULI SUPREMA LEX"

WEDNESDAY, MARCH 9, 1904.

THE DIMINISHING BIRTH-RATE.

THE birth-rate of a nation affords a sure index of its vitality, and denotes with unerring finger the period of its growth, its maturity, and its decay. It is governed by laws that are not yet understood in their entirety, but which it is of the utmost importance should be reduced to a scientific basis. It is with pleasure, therefore, that we publish at length an exhaustive discussion on the subject by Dr. Taylor, of Birmingham, in his recent Inaugural Address to the British Gynæcological Society. Dr. Taylor bases his essay on the theory of Ruskin, that there is no wealth but life, and on the fact that the birth-rate of the United Kingdom is steadily diminishing. The latter proposition is borne out by the gradual decrease of the birth-rate per 1,000 from 34·3 in the five years 1874-78 to 28 in the years 1897-1901. A diminishing birth-rate is not a feature of our own country only, but has occurred also in Austria, Germany, Italy, and France. In the absence of exact information, there is good reason to think a similar fall has taken place in the United States, while it is notably rising in Russia and Japan. In the United Kingdom the marriage-rate has not altered much, so that the lessened birth-rate must be due not to celibacy, but to causes operating in the married life of its inhabitants. The fertility of marriages, in point of fact, has decreased to such an extent that it has been estimated by a statistical authority to mean 26,000 less births per annum in London alone. A mere decrease in quantity might possibly not be an unmixed evil were that attended by a bettering in quality. We are compelled, however, to the conclusion that race deterioration is taking place. The juvenile population of to-day compares unfavourably with a former generation in criminality, in mental diseases, and brain weakness, and even in alcoholism. Dr. Taylor's conclusion is that not only are modern marriages relatively infertile, but that the offspring are weak and neurotic, being specially prone to alcoholism, criminality, and insanity. He further points out that the marriages of the upper and middle classes are now so sterile that an undue and dangerous proportion of the rising generation is recruited from the more ignorant, the more vicious, and the more criminal substratum of society. At the same time it should be remembered that there is no finer foundation for the stamina of a nation than the presence of a large and prosperous labouring element. Coming to the cause of the relative sterility of modern marriages, Dr. Taylor courageously goes to the root of the matter. He says that the elevation of the age of marriage is a small factor, but the main cause is the deliberate use of preventives against conception. Instead of the families of five, twelve, or eighteen children familiar to our grandparents, we commonly find three, two, or one. Dr. Taylor traced various unfavourable results to the use of preventives. He pointed out that the storing of seminal fluid is a source of strength in man and the lower animals. That the testicular secretion has a profound influence upon the bodily economy has been abundantly proved by the researches of Brown-Séquard and Boy Tessier. As regards the female, it has clearly some function beyond fertilisation. As an illustration of that proposition might be taken the neurasthenia that often accompanies sterility due to plugged cervical canal. Then, again, pregnancy plays an important part in giving ovarian rest during its continuance. When the natural cycle is prevented the woman probably suffers far more than she would do from child-bearing. It is a noteworthy fact that the mothers of large families still furnish the finest and healthiest specimens of British matronhood. Prevention, moreover, robs the male of the moral control acquired by the recurring periods of abstention and restraint due to pregnancy and parturition, a quality that is presumably more or less transmissible to his offspring. As regards the child, it is usually the child of the larger family and the poorer parents, often from the lower ranks of society, who pushes his way to the front and elbows out the child whose coming has been carefully "arranged for." The influence of prevention of families upon a nation is undoubtedly great. During the past fifty years in France, although the population has hardly increased at all, yet its criminality has been trebled. In 1830 the suicides amounted to 5 per 100,000 of population as against 24 per 100,000 in 1887, 55 of the latter being under fifteen years of age; whereas in 1896 there were no less than 375 between fifteen and twenty-one years of age. Then, again, is the highly significant fact that since 1880 France has passed from the seventh to the first place among the nations as a consumer of alcohol. After fifty years of limited birth-rate, France appears to be afflicted with a hopeless national neurasthenia which demands constant stimulation in order to face the ordinary routine of life. In considering the possible remedies one must recognise the fact that the forces of modern civilisation appear antagonistic to family life. Religion should inculcate a higher ideal and

a simpler standard of life. The State might afford special relief of taxation to the parents of large families, and by better protection lower the ever receding age at which remunerative work is possible in the learned professions. Medical men would do well to make a closer study of the evils due to limitation of families and educate the laity on the point. Dr. Taylor personally condemned all artificial prevention except in cases of deformity or of grave disease. Almost all labours are safe in the hands of modern surgeons. To artificial prevention must be attributed not merely the diminishing birth-rate, but also the diminishing value of our population. The maximum of life can be attained only by the maximum of virtue; the prevention of life is always accompanied by moral deterioration. This eloquent address on a weighty subject is worthy of earnest study by every member of the medical profession.

COMPOUNDING BY MEDICAL MEN.

This question, recently discussed at the meeting of the Metropolitan Counties Branch of the British Medical Association, where so decisive an expression of adverse opinion was given, touches several matters of grave interest to the profession. Dr. Heron must have foreseen that his proposal to alter the Medical Act by the insertion of prohibitive clauses could never for a moment obtain any support. To endeavour to hamper medical practitioners in the exercise of their undoubted right to compound their own prescriptions was an idea so obviously unpracticable and unjustifiable, that we can only attribute it to a hope on his part that its very extravagance would lead to the discussion of other issues which are inseparably associated with the one he desired to raise. It is profitless to discuss either the necessity or expediency of the compounding of medicines by practitioners. Apart altogether from the question of professional interests there is that of the public need, which in numberless instances cannot be met in any other way than by the practitioner dispensing, for the doctor's medicine as well as his services, in many localities, must go together. Also, even in places where there is an over-abundant supply of chemists, there are populations which cannot afford to pay both doctor and chemist, to whom the physic that goes with the advice is indispensable if they are to seek medical aid at all. A large number of those who crowd our out-patient departments in the hospitals come, as it is, from this class. Nor does the evil, though widely known to exist, decrease. As yet no means has been found to check the shameful abuse of hospitals, and the impositions practised on them by persons who can well afford to pay for advice and medicine which practitioners in their immediate vicinity are willing to give for most moderate fees. Not only that, but it is no uncommon event, having run up bills with their doctor for services rendered by night as well as by day, and for the required medicines, to seek evasion of their debt by going to the out-patient department of the nearest hospital, and, since depreciation of the doctor's services is a necessary part of their dishonest duplicity, to return and spread reports that "the doctors at the hospital" said that the previous treatment had been altogether wrong. Or they have a chemist close at hand who is ready to give "over the counter" advice, and to prescribe for all ailments at the cost of some registered pill or bottle of patent medicine. Thus, the unfortunate practitioner is hard pressed between the abused hospital department on the one hand, and the prescribing chemist on the other. Little wonder is it that "fees," if we can regard the sums paid in the light of these, are so miserably small. It must be so in the face of such competition. There is, of course, the danger that in the further reduction of fees comes the temptation to the practitioner to give the cheapest medicines and thus in some measure find himself recouped for his time and advice. And this is a danger that cannot be ignored. In medicine, as in other matters, necessity is a strong incentive, and even a doctor has "to eat to live." If he can only get a shilling for his advice and medicine, or eighteenpence for his visit and medicine, he must be a man with a strong sense of professional honour and duty to give 50 per cent. of the amount back in the shape of physic. The point is, can anything be done to lessen these evils? Can hospital authorities be induced to make more stringent regulations regarding the notes for the out-patient departments of the legion of hospitals, general and special, that are everywhere springing up? Can the evil of "over the counter" prescribing by chemists be curtailed? We fear that but little can be done to mitigate the latter evil. The Pharmaceutical Society may impose certain conditions with the view of restricting counter prescribing, in the granting of its diploma, but this cannot avail much as long as the practice can be pursued with impunity, and that no penal results follow. For the rest, so far as compounding is concerned, the profession itself is gradually drawing a clear distinction between two classes of practitioners. There is "surgery practice," with its dispensing department and surgery hours, filling a great want for the lower middle classes, and there is the general practitioner who has nothing to say to compounding, and who is rapidly treading on the heels of the consultant. For things are altering quickly, and the high class general practitioner is doing his own work, and only calls in the aid of a consultant on rare occasions of emergency or doubt. Ambition will lead any capable man to desire to join the ranks of the latter. As time goes on these ranks will be largely increased, and surgery practice with its dispensing will be more and more confined to poorer districts, and those in which the services of a pharmaceutical chemist cannot be had. It was unfortunate that at any time the skilled services of the medical adviser should not have been kept entirely apart from the medicines which he prescribed, and that they should have come to be linked with the latter in the medical

charges. One thing is clear—that as long as young men without private means adopt medicine as their profession, and are compelled to accept the low fees at present paid for their services, they will be forced to compound their own prescriptions at least during the earlier years of their professional career.

Notes on Current Topics.

"P.J.F."

ONE of the least admirable features of the proprietary drug trade is that each sample of the preparation has to bear a penny-halfpenny Government stamp. The amount gained from this tax is inconsiderable in proportion to the total revenue, but nevertheless doubtless forms one of the many obstacles to the abolition of the trade in secret medicinal preparations. Moreover, it gives many of the purchasers an idea that the Government guarantee the preparation as possessing, if not all that the advertisers claim for it, at least no noxious properties. Of course, it does nothing of the kind. The boot, indeed, is on the other leg. By recent legal decisions it appears that so long as the ingredients of a medicine, pill, or powder are printed on the outside of the bottle or box, or published in a well-known book of reference, the Government cannot claim stamp-duty; whereas if the vendor does not choose to let people into the wonderful mystery, he must pay his penny-halfpenny. When the article is priced at a shilling or two, he generally prefers to keep the secret locked in his own bosom; but if he only expects a few pence for his preparation, his profits are seriously curtailed if he has to pay the Inland Revenue authorities a penny-halfpenny out of them. To relieve the dispensing chemist of this disadvantage, the *Pharmaceutical Journal* has just brought out a book of 10,000 recipes. By putting on the label of any bottle or box dispensed the cabalistic symbols "P.J.F." ("*Pharmaceutical Journal* Formulary"), followed by the reference number, the chemist will evade the obligation to pay stamp duty. The Formulary will be "A well-known book of reference" in the eye of the law, as the dispenser will find it save him a great deal of trouble. Thus one little drawback to the prescribing chemist's business will be removed, and he will be free to go on and prosper. One doubts if the *Pharmaceutical Journal* will gain in respect from the medical profession by its action in bringing out a book of this kind; but no doubt it has met the convenience of many members of its *clientèle* by so doing.

A Poor-law Infirmary and Puerperal Fever.

THE Bristol Board of Guardians have been faced with a serious state of affairs by the occurrence of two cases of puerperal fever in their lying-in wards. Their Medical Officer has not minced matters, for in reporting the cases above alluded to he said there would always be a risk of lying-in women becoming infected in that way when nurses who were doing ward work—dressing septic cases or working in a ward where such cases were—were allowed to attend midwifery cases. Clearly no nurse should be allowed to tempt providence in that way Indeed, we have no hesitation in saying that any Board of Guardians who permitted such a practice after due warning should be indictable for damages and death from resulting puerperal infection. There is no disease more disastrous and more difficult to eradicate than puerperal fever, yet at the same time it is absolutely preventible by rigorous preventive measures. We note that the occurrence has raised the whole question of the Poor-law Infirmary at Bristol. One of the guardians stated that there were eighty-nine patients in eighty beds, and two of them testified to having seen two patients in one bed. We are happy to believe that so far as England and Scotland are concerned, such a state of affairs is practically obsolete. It is to be hoped that all Poor-law Infirmaries will take the hint from what has happened at Bristol and appoint independent lying-in nurses. Why have the Local Government Board inspectors permitted this overcrowding and improper nursing?

Surgical Diagnosis of Abdominal Conditions.

IT has happened to most surgeons of experience at one time or another to open the abdomen in search for one disorder, and to find something quite different. Many, indeed, have operated for an inflamed or suppurating appendix, and have found the appendix quite healthy. Again, as everyone knows, there is no more difficult point in surgical diagnosis than the recognition of perforation. Only a few days ago we heard of a surgeon of great experience and undoubted diagnostic acumen who, in presence of all the symptoms of acute appendicitis, found a healthy appendix, but a perforated ulcer of the stomach. With such facts before the mind it is perhaps hardly to be wondered at that in hospital practice, at any rate, exploratory operation in doubtful cases is becoming more and more common. In private practice this procedure is not usually so feasible, since before submitting to a serious operation a patient likes, if possible, to get a decided opinion as to the nature of his disease. Nevertheless, we think there is too great a readiness on the part of many surgeons to suggest exploratory section, when some more care might suffice to guide the opinion without resort to operation. As Mr. Tubby remarks, in a recent paper, (*a*) "The method of settling the diagnosis by making an exploratory incision is . . . strongly to be deprecated, because it savours merely of the art of surgery, and not of the science. He is a poor surgeon who finds himself compelled to cut the Gordian knot of his difficulties by acting on the formula, 'Let us open the abdomen and look inside.'" Mr. Tubby goes on to relate some interesting cases of abdominal injury or disease in which the diagnosis was very difficult, and he gives some hints as to the symptoms which he himself has found most useful in diagnosing suppurative inflammations. Special emphasis is laid on an altered relation between pulse-rate and

(*a*) *Brit. Med. Journ.*, February 13th, 1904.

temperature, rigidity, absence of peristalsis, persistent tenderness, and excessive leucocytosis. At the same time, and we think rightly, it is pointed out that the marked prominence of one of these symptoms should nearly always outweigh the absence of others. Special attention to these points through the whole course of an abdominal disease will do much to obviate the necessity of many exploratory operations. At the same time it must be remembered that often even the best surgeon may be left in doubt, and exploration may be not only justifiable, but compulsory.

Ultra-Microscopic Germs.

IN lighting on ultra-microscopic disease germs as a subject for his afternoon lecture at the Royal Dublin Society recently, Dr. McWeeney chose a topic not only of great interest to the lay public who frequent these assemblies, but of deep scientific importance. After the discovery of the bacterial origin of many diseases it was at first thought that all infectious diseases would finally be brought into line by the discovery of a specific organism for each. Repeated failure, however, in the case of many diseases, and these neither unimportant nor uncommon, turned the minds of bacteriologists to the possibility of the specific organism being too small to be seen, even with the most powerful microscope. The wave-length in the case of white light is about $\frac{1}{25000}$ of an inch in length, and particles less than half a wave-length in size can only be seen as little blurred spots. The bacteria with which we are most familiar vary in size from about a micron in diameter to seven or eight micra in length, but it is easy enough to conceive that organisms much smaller may exist, the limit of observation being about quarter of a micron, that is to say, half a wave-length of white light. Germs less than this are by their size quite beyond our ken, yet it is possible that their presence may be made out by their effects, and such has been the fact in various diseases. In the case of pleuro-neumonia of cattle the late Professsor Nocard found out how to grow the microbe in nutritive fluids. They became opalescent from suspended particles too minute to be seen distinctly with the most powerful microscope. Other diseases due to ultra-visible microbes are the so-called foot-and-mouth disease of cattle, the South African rinderpest, and among human maladies yellow fever and in all likelihood hydrophobia. An important point in regard to these germs is that they can pass through filters which are sufficient to block all known bacteria.

Acute Suffocative Pulmonary Œdema.

IN comparatively few of the text-books is there any attention paid to the acute form of pulmonary œdema. Osler, Fagge, and Fowler just mention that such a condition occurs, while Nothnagel, Allbutt, and Gibson pass it over unnoticed. The most complete clinical description is that given many years ago by Dieulafoy. There have, however, been several cases described by individual observers during the past few years, and as the condition is very serious and the treatment somewhat tentative, it is well to call attention to them. The attack is very sudden, and is accompanied by a feeling of suffocation, severe palpitation, excessive dyspnœa, and collapse. The patient is usually cyanosed, and cannot lie down in bed. Cough very soon begins, and there is copious, pink, frothy expectoration, amounting in some cases to as much as a pint in half an hour. A temporary albuminuria occurs. Though the clinical appearance is very distinctive, the pathology is quite vague, beyond that the lungs are very dropsical. In some cases there has been distinct mitral valve disease and in others a fatty heart, but in many it was impossible to find evidence during life of any definite lesion. There is considerable difference of opinion as to the proper treatment. Dr. Steven, of Glasgow, who published a lecture on the subject a year or two ago, (*a*) believing that the collapse was the most pressing condition, strongly advised stimulant treatment, and condemned the use of sedatives as tending to prevent free expectoration. On the other hand, Dr. Lissaman (*b*) found inhalations of chloroform of great use in shortening the duration of attacks, and Dr. Hewlett, in several cases recently reported, (*c*) got equally good results from hypodermic injections of morphia.

The Value of Holmgren's Colour Test.

THE testing of defects of colour-vision is a question of interest, not only to the ophthalmic surgeon, but also to every medical man in general practice. The serious consequences that may arise from the mis-reading of coloured signals are too obvious to need discussion. Under these circumstances it is somewhat disquieting to learn that the most classical and easily applied test for colour-defect is inadequate. That fact was originally pointed out by Dr. Edridge-Green, and subsequently found the subject of investigation by a special committee appointed for the purpose by the Ophthalmological Society of the United Kingdom. Their report has been lately issued. It states that, used in the proper way, Holmgren's test is sufficient to detect a large proportion of cases of colour-blindness, especially when "the defect is of such a kind as to render its possessors liable to make mistakes in common signal lights." At the same time the Committee agree with Dr. Edridge-Green that certain cases cannot be detected by Holmgren's test, however skilfully applied. A supplementary report is promised. Meanwhile it will be well for medical men who are testing candidates for any of the military, naval, mercantile marine, or other service where normal colour-vision is an essential, to bear in mind the fallacy that lurks in the method of Holmgren.

Mediæval Hospitals.

AN interesting account of hospitals in the Middle Ages is contributed to a recent number of the

(*a*) *Lancet*, January 11th, 1902.
(*b*) *Ibid.*, February 8 h, 1902.
(*c*) *Intercolonial Medical Journal of Australasia*, December 20th, 1902.

Dublin Review by Miss Elizabeth Spearman. The organisation of charitable relief to the poor and sick is almost entirely of Christian origin. In Greece and Rome there was little, if any, provision for the needy and though in the East hospitality and charity to the poor are proverbial virtues, yet they were practised individually and without system. The establishment of hospitals in Europe being entirely due to Christian influence, it was but natural that they remained for the most part under ecclesiastical management, and were often merely appendages to the great monasteries. In the Middle Ages medical science was not far advanced, and beyond the ministrations of the monks, who, indeed, were frequently the most learned leeches of the day, there was before the sixteenth century no regular medical service in the hospitals. Their mission was rather to provide rest, food, and spiritual comfort, than to cure the body. The nursing, if ignorant, was careful, and night nurses were provided. In addition to the general hospitals, which were more numerous than one would think, there were many leper houses. Asylums for the insane were few, and treatment was barbarous. Miss Spearman believes that the disappearance of leprosy from Europe is due to the practice of segregation of lepers. In some places, however, this segregation was lax in the extreme, while in others it was sufficiently strict.

Nelson's Arm.

A BLUE-BOOK which has just been issued will have more than ordinary interest for medical men, as it contains extracts from the naval medical officers' journals from 1793 to 1856, and therefore recounts in brief the medical history of those great sea-fights with Napoleon which constitute the most glowing records in our naval annals. Turning the leaves of this book one encounters much that brings before the mind the horrors of surgery in pre-anæsthetic days, and much that is merely grotesque in the way of obsolete remedies. But the extract that will rivet more attention than any other is a description from the log of the surgeon of the "Theseus" of the operation and after-treatment of our greatest admiral when wounded before Santa Cruz. Nelson, it will be remembered, was in the act of stepping out of a boat, which contained part of the landing party that was to storm the town, when he was shot. The musket-ball struck his right arm a little above the elbow, cutting the brachial artery and producing a compound fracture of the humerus. Lieutenant Nisbet rendered timely first aid to his step-father by binding the limb firmly with his handkerchief above the wound, probably saving his life thereby. The invariable treatment of a compound fracture —amputation—was resorted to on Nelson reaching the ship, and he was given "℞ Opii gr. ij. ft. Pil. statim." It is curious to contrast the after-history of the patient as given respectively by the surgeon and by Southey. According to the former, everything went as well as possible, and in a week's time he tells us :—"Continued getting well very fast, stump looked well, no bad symptom, sore reduced to the size of a shilling." Southey says that Nelson's sufferings were long and painful, and that it was not till the final ligature came away at the end of November that he got rid of the pain and the wound began to heal.

Radium at Bath.

THE good citizens of Bath appear to be somewhat unduly elated at the discovery of radium in their renowned hot springs. A few days ago their Mayor offered his warm congratulations to the Town Council on the discovery of this most up-to-date constituent in connection with what has always constituted, so to speak, the backbone of Bath. Can the Romans with splendid intuition have recognised the effects of dormant radium in their beloved hot baths? Or was not the discovery first made by a sagacious hog, who revealed the virtues to a Saxon King by wallowing in the warm mud around which the city of Bath grew and multiplied and has ever since flourished? Is the claim of priority of discovery of the radium in Bath springs to be conferred upon hog, or Saxon King, or Roman, or the modern analytical chemist? Whatever answer may be given by posterity to that important question, we fancy the Mayor has somewhat over-estimated the value of the radium in the famous mineral waters of his ancient city. The baths will be no better and no worse than they have been during many bygone centuries. The quantity of this revolutionary element is so minute that it would not repay extraction, which is the only way in which the Bath Corporation would be likely to make money out of their radium mine. It is possible, however, that some visitors may be attracted to the city with the object of bathing in water charged with so precious and fashionable a medicinal agent. So mote it be!

Hospital Amalgamation in Dublin.

AN interesting event took place the other day in Dublin in the completion of the scheme for the union of the two ophthalmic hospitals. For many years St. Mark's and the National Eye and Ear Hospital have, pending the construction of the new building, been working as separate branches of one institution. A few months ago, however, the necessary part of the building was completed, and the patients are now all lodged in what is known as the Royal Victoria Eye and Ear Hospital in Adelaide Road. The out-patient department and another wing are still to be built, but we understand that the Board do not intend to proceed until funds are forthcoming, although the institution is at present free from debt. As Mr. Swanzy pointed out in his speech at the annual meeting on the 25th ult., the amalgamation of these two special hospitals is only part of a much more general scheme proposed twenty years ago. During Lord Spencer's viceroyalty there was much talk of amalgamating Dublin hospitals, and he appointed a Commission to inquire into the matter and make recommendations. In the Report the amalgamation of some

of the general hospitals on either side of the city was recommended, but the solitary fruit of the Commission is the Royal Victoria Hospital. We cannot help thinking that Dublin would gain if some of the smaller general hospitals would seriously think of copying the special hospitals in this direction.

The Purity of Sweets

THE universal sweetmeat has long and often been a subject of suspicion to vigilant custodians of the public health, and over and over again analyses have been made to see if the variegated dainties that are sucked by the children of the poor are not doing more harm than merely stimulating early dental caries. It is comforting to think that cheap sweets are generally found to be above reproach, a result which is due to the cheapness of sugar itself. It simply does not pay to adulterate as it is difficult to find any substance wherewith to sophisticate sweetments that is cheaper than sugar itself. To this reason more, one would be inclined to think, than to the unflinching moral rectitude of the lower order of confection-mongers is due the harmlessness of the pear-drop, aniseed balls, and bull's-eyes that tickle the palates of the street urchins. Vegetable essences to flavour the sweets are also very cheap, and aniline dyes are very little used. Whether a rise in the price of sugar by taxation and the abolition of bounties will lead to more frequent adulteration is a point to be watched, but in the meantime it may be said fairly safely that wee MacGreegor's "taiblet" is, if taken in a moderation to which he appears to have been averse, quite as wholesome as any other part of his diet.

Adrenalin in Acute Glaucoma.

THE pathology of acute glaucoma has been variously described as being due to a retention of the intra-ocular fluids or to their hyper-secretion. While modern ophthalmological opinion is inclined towards the acceptance of the former theory, there can be little doubt that vascular congestion plays no small part in the production of the glaucomatous state. The performance of iridectomy and the use of myotics have, up to the present time, constituted the main forms of treatment. The anti-glaucomatous effect of a myotic depends, of course, entirely upon its power of bringing about contraction of the pupil, and if this cannot be done the drug is valueless. M. Grandclément (*a*) showed at a recent meeting of the Société des Sciences Médicales, of Lyons, a patient, aged thirty-seven, in whom he had cured an attack of acute glaucoma by the instillation of adrenalin. The strength employed was 1 in 5,000, and the solution was dropped into the affected eye every half-hour for three consecutive days. It has been found experimentally that suprarenal extract arrests the formation of the aqueous humour in the eyes of animals, and, therefore, diminishes intra-ocular tension. In the discussion which followed the exhibition of the case, M. Aurand stated that he had used adrenalin in a case of double glaucoma, in which relief of pain and some contraction of the pupil were obtained, but he performed iridectomy afterwards. Until it can be proved that this beneficial effect of adrenalin is more than temporary, it is doubtful whether this powerful vaso-constrictor will find favour with ophthalmic surgeons. If it be established that operation affords the best chances of success in acute glaucoma, there can be no object in wasting time by employing less radical measures. We have by no means exhausted the therapeutical possibilities of suprarenal extract, and its use in this department of surgery may, after further experiment, be found of service.

(*a*) *Lyon Medicale*, February 14th, 1904.

Nurses of Yore.

THE nursing profession is advancing every day, and if the Bill for the registration of its members passes into law (which seems very unlikely this session) it will acquire a status that will not be grudged to it by those who know the value of a trustworthy and skilled nurse. It is amusing to read in the records of one of our big hospitals that the salary of a sister in the year 1552 was only 40s., whilst a "herb-woman" was in receipt of double that sum. The sisters of the present day are not overpaid, but most of them would not find devotion to their work sufficient to carry them through the year with only two pounds to spend on dress and amusements. The restrictions placed on the sisters' movements were considerably greater than they are now. The "late pass"—or, indeed—any pass—did not exist, as there is a record of three sisters being threatened with discharge for going about the town, and this severe penalty was to be inflicted "yf they doe the like hereafter." The amorous house-surgeon, or his homologues, would seem to have been more or less *en évidence* even in 1552, for the sisters were bidden to beware the machinations of the males about the hospital precincts. The rule enjoined that no one "should talk susspitiously nor contract matrimony with each other within the house." One sister who ventured to "carry on" in spite of this rule was so far successful in her object as to be "axte in church" by her swain. On being handed over by the authorities to the matron's "discressyon" she seems to have found but little favour with that adamantine female, for she was politely requested not to "remayne." The work of the modern nurse may present a marked contrast to that of her prototype of three and a half centuries ago, but her predilections and weaknesses seem to have undergone but little alteration, and it would seem that the rules relating to her discipline have not substantially changed in principle.

Phalangeal Enlargement in Rickets.

ALTHOUGH affecting more or less the whole system, the stress of rickets appears to fall most heavily upon the osseous structures. The characteristic epiphyseal thickenings, many of which bear distinctive names, are early brought before the notice of the student of medicine, who soon

learns to recognise the "rickety rosary" and other bony abnormalities met with in the course of the disease. Dr. Jacob Sobel, (*a*) of New York, has called attention to the fact that enlargement of the bones of the phalanges is not unfrequently seen in true infantile rickets, and, indeed, is often overlooked. The condition is one of true bony hypertrophy, though the clinical appearances sometimes resemble very strongly those seen in strumous or syphilitic dactylitis. There is, however, an absence of the dusky hue which generally accompanies tuberculous lesions of the phalanges, and other signs of rickets may be found elsewhere. The diagnosis from syphilitic dactylitis may be more difficult, especially as enlargement of the spleen occurs in both affections. With morbus cordis of congenital origin associated with clubbing of the fingers it is hardly likely that there would be confusion. Dr. Sobel quotes the experience of Dr. Rudolph Neurath, who has found that periosteal thickening may be easily demonstrated in these cases by means of the X-rays, the interior of the bone being practically unaffected. The term "rhachitic dactylitis" is suggested for the condition which principally affects the phalanges of the upper extremities.

The Complications of Measles.

THE acute exanthemata, as a class, are not so much to be dreaded for their own sake as on account of the many and varied complications by which they are so often accompanied, or the sequelæ which sometimes follow in their wake. The secondary lesions, from their gravity and importance, are naturally feared more than the disease itself, and it is for their prevention that the skilful practitioner earnestly strives. The readiness with which the general public are apt to make light of the milder varieties of the acute specific fevers, calling them—as they do—"only children's complaints," and, perhaps, treating them themselves by the aid of some popular handbook of household medicine, contributes in no small degree to the really high comparative mortality associated with these diseases. It is notorious, for instance, that the epidemic form of measles is by no means the simple affection it is supposed to be, for statistical returns show the death-rate to be considerable, especially in poor districts and among ill-fed or wasted infants. Complications of a pulmonary nature are chiefly responsible for the fatal issue in measles, capillary bronchitis and broncho-pneumonia being specially prone to occur. Acute nephritis is not often seen as a complication in this disease, and many textbooks of medicine do not mention it. A case of this nature, reported in the *Guy's Hospital Gazette*, is worthy of notice in this connection as showing that nephritis may be absolutely unsuspected during life and yet may be the actual cause of death. An infant of ten months was admitted with a typical morbilliform eruption and signs of bronchitis. A week later diarrhœa supervened, which increased in severity in spite of treatment until the child's death thirteen days later. At the autopsy the kidneys were found to weigh ninety grammes and to present all the appearances of acute nephritis. No dropsy was present during life. Cases such as these only serve to illustrate the clinical importance of giving a guarded prognosis as long as any unfavourable symptoms in the course of measles are manifest.

(*a*) *Medical News*, Feb. 13th, 1904.

Latent Disease in Childhood.

As "sickly plants betray a niggard earth," so surely does the weakly condition of the child reveal the quality or constitution of the soil from which it has sprung and the heritage which comprises its physical capital. It is true that many puny infants ultimately develop into a state which may pass for comparative or even excellent health as the result of incessant watchfulness and persevering care; but when they are put to the sharp test of a severe illness their lack of staying power is only too conspicuous. The modern life of board-school children, as portrayed in the daily press, shows unmistakably that a large proportion of these little ones are absolutely unfitted for the stress and strain of an ordinary school education, while numerous instances have come to light where the increased demands placed upon their feeble reserve power in the shape of some kind of work undertaken in "out-of-school hours" have been responsible for an utter physical breakdown. To a great extent, this incapacity for work is due to improper feeding, which is, in its turn, the direct result of parental ignorance. There is little wonder then, that under such circumstances any latent tendency to disease which may be constitutionally present in these children ceases to be a mere predisposition, but develops into some actual morbid state. Tuberculosis, in one of its many varieties, is the malady which is most often developed in this way. As Dr. Robert Jones remarked in his lecture before the Society of Arts, last week, the amount of physical deficiency and latent disease found among a considerable number of the poorer class of school children was enough to "sadden a medical expert." The truth of these words can only be fully appreciated by those who have themselves personally conducted the medical examination of these little ones. How to prevent potential or latent disease from becoming an actuality is one of the problems which should engage our utmost attention.

An Advance in Entero-Anastomosis.

FROM time to time surgeons in various parts of the world have devoted a good deal of ingenuity to the anastomosing of stomach and gut. Of special devices, perhaps none is more widely known than Murphy's button. In the next issue of THE MEDICAL PRESS AND CIRCULAR will appear an account of a novel method of anastomosing stomach and bowel without opening into the lumen of either viscus, sent by our Austrian correspondent. The special operation appears to have been performed only on dogs and monkeys, and has not

yet been tried on the human subject. Sato, who has devised this most ingenious procedure, removes the muscular and submucous coats of the stomach and intestine over the parts it is desired to unite. Nitrate of silver is then applied to the mucous membrane of both bowel and stomach, which are then brought together and fastened in position by a few sero-muscular sutures. A free communication follows after two days in the monkey, and three in the dog. Should the feasibility and safety of this method become established, it will obviously do much to simplify and to render safer anastomosing operations of the kind mentioned. The principle, moreover, is capable of extension. Whether ultimately adopted or not, the proposal is typical of the restless ingenuity and daring of modern surgery.

Latent or Intermittent Nasal Obstruction.

The physiology of the upper air passages is sometimes apt to escape due recognition by those who make a special study of the nose and throat. That its careful consideration is capable of furnishing fresh and valuable data is shown by the able and original article published elsewhere in our columns by Mr. Mayo Collier. He points out that the naso-pharyngeal tract is not a simple tube, but a canal that widens out here and there into reservoirs, which provide mixing chambers for the inspired fresh air. Otherwise it would be impossible for the nasal passages to "warm, moisten and purify air" that passes through the nose in an average space of two seconds. Mr. Collier has called attention to an often unsuspected condition, where the patient breathes through the nose in the daytime, but during the night becomes a "mouth-breather." The consequences are of the usual kind, but the observer is, maybe, thrown off his guard by a confident denial of mouth breathing on the part of his patient. The author states that the groove on the septum is in most cases the only objective sign of this state of affairs, but it is fortunately constant and pathognomonic.

The Irish National Hospital for Consumption.

The Annual Report of the Royal National Hospital for Consumption for Ireland presented last week gives fresh evidence of the valuable work which is being done by that institution. During the year 1903, 265 patients were discharged after treatment, of whom 204 were improved. Many presented, at the time of discharge, no sign of disease, and were, to all appearance, cured. Eighty-five per cent. of the entire number of patients treated showed an increase in weight, the highest individual gain being 2st. 5lbs. Dr. Steede, the resident physician, is, however, properly cautious about drawing conclusions from very recent cases, and he adds to his report extracts from letters received from former patients who were treated in the early days of the hospital six or seven years ago. Many of these old patients are in excellent health, and have been at their regular employment since leaving Newcastle. In the body of the hospital it is necessary, owing to constant applications for admission, to restrict each patient's stay to a period of about three months. Messrs. Guinness and Sons, however, maintain one ward for the use of their employees, and are able, as a rule, to permit a longer stay. For this reason the report of their medical officer, Dr. Lumsden, is of particular interest, and it would be hard to find more satisfactory evidence of the efficacy of the treatment at Newcastle. He relates that every patient he sent to the Hospital improved greatly, and most of them are, he believes, cured. Without the treatment they received they were all, in his opinion, doomed to speedy death. When our Commissioner visited the hospital last autumn, he recommended (*a*) the establishment of a dispensary in Dublin, where old patients could be kept under observation, candidates for admission examined, and instruction given to unsuitable patients. We are glad to see that the Board intend shortly to carry out this suggestion, but at present they have their hands full in building a new wing for females.

PERSONAL.

The medical profession will learn with pleasure that Sir Samuel Wilks is now well on the road to recovery from his recent operation.

Dr. de Havilland Hall presided at the annual dinner of the Medical Society of London, held yesterday evening at the Hotel Métropole, London.

The newly-appointed Demonstrator of Hygiene and Public Health at University College, London, is Mr. G. E. Richmond, M.D., B.S., B.A., B.Sc.Lond., D.P.H.Camb.

Deputy-Inspector-General of Hospitals and Fleets Herbert Mackay Ellis has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

Dr. T. G. Brodie, Professor of Physiology at the Royal Veterinary College and Superintendent of the Brown Institute, is one of the new Fellows of the Royal Society.

Among others of the fifteen new Fellows are Dr. G. H. F. Nuttall, University Lecturer in Bacteriology and Preventive Medicine at Cambridge; and Professor A. E. Shipley, the well-known Cambridge lecturer upon invertebrate morphology.

A fellowship of the value of £100 a year for three years has been founded in the University of Liverpool by Mr. W. Thelwall Thomas, assistant surgeon to the Royal Liverpool Infirmary.

The King, although unable to attend the State service at St. Paul's on Sunday last, recovered from his recent indisposition sufficiently to preside at a Privy Council on Monday, the 7th inst.

Sir Thomas R. Fraser, M.D., F.R.S., Professor of Materia Medica and Clinical Medicine in the University of Edinburgh, has had the well-deserved honour conferred on him of appointment as an Honorary Physician to His Majesty the King in Scotland.

(*a*) The Medical Press and Circular, September 30th, 1903.

THE two remaining Hunterian lectures on the "Pathology and Surgery of the Pancreas," will be delivered before the Royal College of Surgeons by Professor Mayo Robson on March 9th, and 11th, at 5 p.m. each day.

PROFESSOR BOYCE, Dean of the Liverpool School of Tropical Medicine, on his return from Egypt, where he has been investigating malaria, was entertained last week at a complimentary luncheon by Sir Alfred Jones, K.C.M.G., and a distinguished company.

SIR WILLIAM TURNER, K.C.B., was the guest of the Royal Medical Society on the 3rd instant, in the Hall of the Society at Edinburgh. The President of the evening was Dr. Fitzwilliams, and there was a large and distinguished attendance of medical men.

THE Council of Owens College recently invited Dr. Mott and Mr. Brudenell Carter to deliver two lectures to the medical men of Manchester and the neighbouring districts. The first of these lectures was delivered on February 19th by Dr. Mott, on "The Cerebro-Spinal Fluid and its Relation to Diseases of the Nervous System."

Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

SCOTLAND.

ROYAL EDINBURGH ASYLUM FOR THE INSANE.—Dr. Clouston's annual report of the asylum, which is always well worth reading, was adopted at the meeting of the Asylum Corporation on February 29th. The first paragraph of the report deals mainly with statistics, and the main feature of the admissions for the year was the number of cases of aged and broken-down people, of general paralytics, and of alcoholics. The prevalence of tuberculosis, four times as common in asylums as among the general population, was now attracting an enormous amount of attention. At the Edinburgh Asylum, 16 per cent. of the deaths were associated with tuberculosis, while in 13·5 per cent. it was the sole cause. On going over the statistics he was astounded to find that in Craig House there had only been three deaths in nine years, that these were imported cases, and that no case of tuberculosis had ever arisen there. While this was a striking testimony to the thoroughness of the measures taken to prevent infection spreading in Craig House, it, of course, meant that the amount of tuberculosis in the West House was correspondingly higher—22·5 per 1,000 inmates, and 14·5 per cent. of the total deaths, as against the English numbers of 18·2 and 16·9. As might be expected, during the last nine years, since they became distinctly overcrowded, tuberculosis had distinctly increased. The general death-rate of the whole institution was 13 per cent. on the average numbers resident, and 8·8 per cent on the totals under treatment.

LUNACY-RATE FOR THIRTY YEARS.—In 1873 one insane person was chargeable on the rates for every 413 of the population of Edinburgh and Leith; in 1883, the number was the same; in 1893, there was one to 379; in 1903, one to 315. These figures probably corresponded pretty closely with the general Scottish rate. The increase of insane persons did not mean any great increase in insanity, but was due to the fact that people were less afraid of asylums, to the enlargement of the area of what constituted certifiable mental defect, and to the prolongation of life of patients in asylums. The proportion of one rate-paid patient to every 315 of the population did not, however, represent our whole mental defect. When every person affected with any form of mental disease or weakness was included, there was a proportion of one to 230 of the population of Edinburgh, and of one to 220 for Scotland generally. The extremes were one to 118 in Argyll and one to 334 in Dumbarton. Argyll, however, sent out a large proportion of sane, energetic young adults to work in Glasgow and Dumbarton, while insane and weak-minded ones were left at home on the rates. Dumbarton produced yearly more acute insanity than Argyll, but this was a kind of insanity which either killed its victims soon, or allowed them to recover rapidly. In any case, it did not run up the number of permanent weak-minded. The low infant death-rate of Argyll meant the survival of imbeciles; the high rate of Dumbarton killed off the imbeciles with the rest. The care of child life ought to have a better reward than the burden of supporting so many imbeciles out of the rates. The cost of lunacy was high, chiefly on account of this class, in Orkney and Shetland, where the death-rate under ten years was only 11 per 1,000—a record, compared with the 37·5 per 1,000 mortality of Lanark. During the thirty years the recovery-rate had decreased and the death-rate increased. This was due largely to increased admissions of senile insanity and of general paralysis. Adolescent insanity had also become more prevalent. Alcoholic insanity was steadily going up; this year no fewer than 42·3 per cent. of men and 18 per cent. of women admitted had excess in alcohol assigned as a cause of insanity. The percentage had steadily risen in the thirty years, until now it had doubled itself. One of the after-effects of the nervous lowering which the influenza epidemic of 1890 undoubtedly caused might have been the craving for the stimulus of alcohol. Undoubtedly since that time far more cases of depressive insanity had been admitted. Possibly, too, more money was earned by those who had not self-restraint to use it rightly. It was satisfactory to learn that some forms of insanity—epileptic, and those connected with child-bearing—had become relatively less frequent. It was much to be desired that the public should take a rational view of mental disease, and look on it as a disease of the brain—like a disease of any other organ. In about a third of the cases it was due to arrest of development or disturbance of growth during adolescence; in about a sixth to premature senility. In the remainder it was thought to be due to toxæmia, to which heredity predisposed. Such terms "idiot" or "madman" should cease to be used as terms of reproach. The world would gain if only a rational view of mental disease were universally taken and the facts about it manfully faced.

ROYAL MEDICAL SOCIETY'S ANNUAL DINNER.—This function was held in the society's hall on March 3rd, Dr. Fitzwilliams, who presided, having on his right the guest of the evening, Principal Sir William Turner. The dinner was largely attended by the principal medical men in Edinburgh, and universal regret was felt that, on account of illness, Dr. Shaw, the Senior President, was unable to be present.

CHALMERS HOSPITAL, EDINBURGH.—After holding the appointment of surgeon to this hospital for nearly forty years, Sir Patrick Heron Watson will retire on October 1st next. He will maintain his connection with the hospital in the capacity of consulting surgeon, and a bed in each ward will be named the Heron Watson Bed in recognition of the eminent services he has rendered during that long period.

Correspondence.

[We do not hold ourselves responsible for the opinion of the correspondents.]

THE LEGAL AND MEDICAL PROFESSIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The spirit of friendly relationship that formerly existed between the professions of law and medicine, and the courtesy that was its natural expression, seem to have departed altogether in our times, or to be recalled only by the occasion of social functions outside the sphere of professional work. Anyone who has had experience of the system that presently obtains in the Courts cannot fail to have been struck by the unwarranted impertinence—frequently amounting to positive insult—to which medical witnesses are constantly subjected, as if it were a

recognised fact that every medical witness must not only be prejudiced, but prepared to sacrifice his professional honour and degrade his office in the interests of whatever party has employed him.

It is not an infrequent occurrence to find judges priding themselves upon the knowledge of petty medical technicalities, and parading it in a series of questions that should certainly arouse indignant protest, if it did not afford compensation in the silent amusement of the doctor who happens to be pilloried in the witness-box.

Lectures regarding excessive fees and the unreasonable requirements of medical men are occasionally contributed, and irresistibly force one to the conclusion that "M'lud" has been a diligent student of the introductory remarks to the advertisements of patent medicines. The Bar, of course, takes its cue from the Bench, and the method of cross-examination of a medical witness bears frequently a close resemblance to the Petty Sessions Court style, where the evidence of a doubtful character is being sifted.

Formerly the cross-examination of medical witnesses was directed to minimise the injuries alleged to have taken place, and the most vigorous investigation of facts did not preclude the observance of that old-timed courtesy that was honourable alike to both professions. Now, however, the medical man is subjected to every indignity, his motives are impugned, and his testimony regarded as, at least, not above suspicion.

That this is the actual state of things can scarcely be gainsaid, the reason for it may be debatable. It does assuredly seem that the present duty of medical witnesses is to resent immediately and resolutely any insulting observations or insinuations addressed to them in a court of justice, whether they emanate from the judge or counsel.

I am, Sir, yours truly,
E. MAGENNIS, M.D., D.P.H.

37 Harcourt Street, Dublin.

THE MEDICAL PROFESSION IN IRELAND AND THE PRIVATE ENTREE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to forward you, for publication, the following letter from the Private Secretary of his Excellency the Lord Lieutenant, which was read at the monthly meeting of the President and Fellows of the Royal College of Physicians of Ireland held this day.—Truly yours,

JAMES CRAIG, M.D.,
Fellow and Registrar.

Royal College of Physicians of Ireland,
Dublin, March 4th, 1904.

"The Castle, Dublin,
"26th Feb., 1904.

"Dear Sir,—With reference to the question of the Private Entrée at Dublin Castle, I am directed to request you to inform your Council that, after careful consideration of all the circumstances of the case, the Lord-Lieutenant has decided not to carry out the changes he contemplated, but to adhere to the rules under which up to the present it has been regulated. His Excellency trusts that this decision will be in all respects satisfactory to your Council, and to the profession it represents.—I am, faithfully yours,

"(Signed), PLUNKET.

"The Registrar,
"Royal College of Physicians of Ireland."

Obituary.

DENIS NYHAN, L.B.C.S., L.R.C.P.EDIN., BRYNMAWR.

WE regret to announce the death of Dr. Dennis Nyhan, medical officer of health for Brynmawr, on the 1st inst., from pneumonia, with which he was seized only four days previously. A large and representative attendance which met at the London and North-Western Railway Station, where the mourning party entrained for New Milford, *en route* for Cork, testified to the esteem in which deceased was held. The cortège included members of public bodies, friendly societies, and a large number of his professional brethren from different parts of the Principality. The coffin was covered with wreaths. Deceased came to Brynmawr nearly eight years ago as assistant to the late Dr. Alexander Lowe, M.B., whose practice he acquired. Upon arrival at Cork the remains were removed to Kilnagross, near Clonakilty, his native place, where the interment took place on Friday last.

ALEXANDER DAVIDSON, M.D.EDIN., F.R.C.P.LOND. M.A.,

THE death is announced of Dr. Alexander Davidson, of 2 Gambier Terrace, Liverpool, at the age of 66 years. The deceased, who had been ill for some time, expired on March 3rd, and was buried in Smithdown Road Cemetery, after private cremation. Dr. Davidson, who had a practice in Liverpool, obtained his degrees from Edinburgh and London, and held honorary office as physician, and, later, as consulting physician, at the Northern Hospital and the Royal Infirmary. In former times he was one of several lecturers on clinical medicine at the University College, now the Liverpool University. He was professor of pathology in the Liverpool School of Medicine, and on retiring was made Emeritus Professor of Pathology of University College.

J. D. DIXON, M.B.DUR., M.R.C.S.ENG.

WE regret to announce the death of Dr. J. D. Dixon, a well-known and highly esteemed member of the medical profession of Gateshead, son of the late Dr. Dixon, of that town. He was educated at Durham University, where he graduated M.B. in 1878, having previously taken the M.R.C.S.Eng. in 1875. The deceased was at one time house surgeon of Newcastle Infirmary, and subsequently joined the staff of the Dispensary. He afterwards entered into private practice, and in the course of time, owing to somewhat ailing health, took up his abode at Harrogate. Lately he went to live at Southsea, where he died on Monday of last week, and was interred there on Thursday. Dr. Dixon about ten years ago married Miss Kate M. Clarke, daughter of Mr. Clarke, of the firm of Clarke, Chapman and Co. He was only fifty years of age, and leaves a widow and three children. He held a prominent position in Freemasonry, and took high honours in the Province,

Literature.

BEALE'S AIDS TO PHYSIOLOGY.* (*a*)

THE volume under review forms one of the latest additions to the "Students' Aids Series." For some time past there has been a felt want in regard to a handy summary of the facts regarding physiology. This want has at last been supplied, and students are under a deep debt of gratitude to the author of these "Aids" for the trouble he has taken in condensing so large a subject as physiology within the compass of 230 pages. It might be considered hardly possible or even advisable to epitomise so important a subject as this, but at the present time students absolutely must have such handy guides as these to help them in finding their way about in the maze of subjects through which they are forced to journey. Turning to the book itself, we find that each one of the twenty chapters of which it is made up is characterised by conciseness of diction and definiteness of statement. The illustrations, for a small book of this kind, are numerous and exceptionally clear and helpful. The book certainly presents as good a summary of modern physiology as one would wish for or expect. Students in particular will derive much benefit from a careful study of its pages just before examination, while prac-

(*a*) "Aids to Physiology." By Peyton T. B. Beale, F.R.C.S.Eng., Examiner in Physiology to the Society of Apothecaries, Lecturer in Physiology and Histology, King's College &c. Pp. vi, 259. Price 3s. 6d. London: Bailliere, Tindall and Cox. 1903.

titioners who do not consider themselves too old to learn will find within its pages much that differs from the physiology as taught in earlier days, and which is instructive and absolutely essential if they desire to keep pace with modern research and its teachings. We have little doubt that yet another edition of this masterpiece of conciseness will not be long in being called for, and if such be the case we may suggest that the author extend the usefulness of the book by adding to the short chapter on development, as this has recently become a very important subject at certain examinations. Otherwise we have no further suggestions as to improvement of a work which has only to be seen to be appreciated.

DOCTORS AND THEIR WORK. (*a*)

THIS charming collection of essays dealing with matters medical, although apparently addressed to the intelligent layman, should also be studied by the family practitioner, the fashionable consultant, and that enigma of possibilities, the medical student. Mr. Carter writes out of the fulness of a wide and varied experience. Every chapter gives evidence of keenness in observation, patient thought, painstaking research, and intense sympathy with all that is of human interest in medical science and politics. The primary object of the author appears to bring about a better understanding of medical objects and methods, and he certainly has spared no pains in his endeavours to show how patients may best co-operate with their physicians for the attainment of ends which both classes are bound to regard as of the first importance, the relief of suffering and the prolongation of life. Mr. Carter writes in a peculiarly attractive style, and with a winning turn of phraseology and a pretty touch of humour, features all too rare in much of medical writing of the present day. We do not pretend to agree with Mr. Carter in all his precepts, and it is certain he will not escape scathless from his colleagues north of the Border respecting some of his strictures on the influence of Scotch education. But in spite of his admiration for London as the natural centre of all that is most meritorious in medicine, and a tendency to profuseness sometimes verging on wearisomeness, his book is a peculiarly opportune one, and merits careful consideration. Among so much that is excellent, it is almost impossible to differentiate, but particular attention may be directed to the sections dealing with the wishes of the patient, the hindrances to medicine, specialism and medical "etiquette." The chapter on medical women is short but judicious, and to the point. We commend the book to practitioner and patient. An endeavour to profit by Dr. Carter's advice should do much to smooth the path for all.

DISEASE IN CHILDREN. (*b*)

THIS, the third volume of the Reports of the Society for the Study of Disease in Children, fully maintains the standard of its predecessors. The most important event in the work of the year with which the volume deals was a discussion on tuberculous peritonitis, at which a number of valuable papers, published *in extenso* here, were communicated. Among a number of shorter articles and records of interesting cases we have papers by Carpenter on myocarditis, syphilitic nephritis, and splenomegaly, by Ashby and Stephenson on acute amaurosis following infantile convulsions, by Sutherland on syphilitic nephritis, and by Tubby on the urban hospital treatment of surgical tuberculosis. We have not space to mention even a fraction of the other communications, suffice it to say that with each year of its appearance the series of reports becomes a more and more valuable treasure-house of facts concerning both the more obscure and the commoner diseases of children, and will, we are sure, be a great source of help to workers at this branch of medical practice.

(*a*) "Doctors and their Work, or Medicine, Quackery, and Disease." By Robert Brudenell Carter. F.R.C.S., Consulting Ophthalmic Surgeon to St. George's Hospital, and to the National Hospital for the Paralysed and Epileptic. Pp. 316. London. Smith, Elder and Co. 1903.

(*b*) "Report of the Society for the Study of Disease in Children." Vol. III. London. 1903.

Medical News.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429 Strand, W.C., on the 26th ult. There were present the Chairman, Dr. De Havilland Hall, Dr. Frederick S. Palmer, Dr. J. W. Hunt, Mr. F. S. Edwards, Dr. W. Knowsley Sibley, Dr. M. Greenwood, Mr. E. Bartlett, Dr. H. P. Symonds, Dr. J. F. Allan, and Dr. J. B. Ball. The business of the society is in a satisfactory condition. The inclement weather in the early part of the year always produces a large number of claims on the Sickness Fund, but so far those received in 1904 have not exceeded the expectation either in number or amount. A large proportion of these claims have arisen through influenza, a malady to which members of the medical profession seem specially liable, but considering that many of the members have arrived at an age when attacks of this kind have to be carefully attended to, the total amount disbursed by the society is not excessive. Prospectuses and all particulars on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

Marmorek's Serum in Tuberculosis.

Two patients at the Notre Dame Hospital, Montreal, one suffering from tuberculosis of the lungs, the other from tuberculosis of the knee-joint, have recently been treated by injections of Marmorek's serum. The injections were made under the supervision of Dr. L. J. Lemieux, of Montreal, who has lately returned from Paris, where he states that he saw twenty-five cases in which consumption was cured by means of this method. He brought back with him serum sufficient for the treatment of fifteen patients. This is said to be the first time the serum has been employed in Canada.

Irish Medical Schools' and Graduates' Association.

WE are asked to announce that the annual Festival Dinner of the above Association will take place in London at the Trocadero Restaurant, Piccadilly Circus, on St. Patrick's Day, March 17th next, at 7.15 p.m. Tickets may be obtained by members from Mr. E. Canny Ryall, 30 Harley Street, W.

Prudential Assurance.

THE fifty-fifth annual report of the Prudential Assurance Company is now before us, the figures being truly amazing. As the largest office in the world, its assets amount to the astounding sum of nearly fifty-two millions sterling, the number of policies in force at the end of last year was 712,097, the premiums received during the year £9,661,410, and the claims paid during the same period £3,624,510. Happy the members and policy-holders of an insurance company which can show a total surplus for the year of £2,194,981.

Post-Graduate Classes in Dublin University.

WE are glad to learn that the authorities in the School of Physic in Trinity College have, with the sanction of the Board, taken the important step of instituting post-graduate courses in all the subjects that are required for the examinations of the Indian and Home Army Medical Service and the Navy Medical Service. It has been a distinct drawback in the past that nowhere in Dublin were there established anything in the nature of post-graduate courses, and such an omission necessarily resulted in many men being driven to London or elsewhere when preparing for the different Services. Once the establishment of the new classes is known, we are sure that they will be largely attended, and in this connection we must draw special attention to the fact that no limitation is placed on those desirous of attending the classes, which are open to every qualified medical man. Further particulars will be found in our advertisement columns,

and a list of the gentlemen whom the Board of Trinity College have appointed to lecture.

Dentists for Soldiers.

WE are officially informed that at the beginning of April eight dental surgeons will be appointed to attend the troops in the United Kingdom. They will be required to devote the whole of their time to Army work, and will be paid £365 a year, exclusive of travelling expenses. As at present arranged, they will be stationed at Aldershot, Devonport, Cork, Edinburgh, Portsmouth, Dublin, Colchester, and Woolwich. They will, however, be required to give attendance as ordered by the officers in command of the various stations. Applications for these appointments should be made to the Secretary of the Army Council, 68, Victoria Street, S.W., not later than March 12th.

Malaria in Egypt.

AT a luncheon given last week by Sir Alfred Jones, President of the Liverpool Chamber of Commerce, to Dr. Boyce, Holt Professor of Pathology in Liverpool University, on his return from Egypt, where he has been to inquire into the result of the Anti-malarial Expedition, which was sent to Ismailia by the Liverpool School of Tropical Medicine, about eighteen months ago. Professor Boyce stated that as a result of the campaign against the malaria-bearing mosquito, which was instituted at Ismalia by Major Ronald Ross, the average number of cases of malaria had fallen from something like 2,000 per annum to 200. There had been no deaths among Europeans during the past year, and only four amongst the natives, as against thirty deaths in the previous year. The enormous improvement which had been effected in the health of Ismailia was a source of great gratification to the Suez Canal Company, and especially to Prince D'Arenberg, the chairman of the company, who had interested himself most deeply in the Anti-malarial Campaign. The achievements in Ismailia ought to encourage them to go forward in earnest in the work of fighting malaria in West Africa. They could now go to the Government with this Report from Ismailia and ask that similar action be taken in those British Colonies where malaria was prevalent.

Society of Medical Phonographers.

THE annual shorthand examination by this Society will be held in May, 1904. Two prizes will be offered, each of the value of £3, one for first year students and one for students of more than one year's standing. The competition will be open, without entrance fee, to any registered medical student in the United Kingdom who has not taken a first prize at one of the Society's previous examinations. Intending candidates should send in their names as early as possible, and in any case before April 15th, to Dr. P. G. Griffith, Villa Molitor, Green Lanes, Hornsey, N., who will supply a detailed prospectus of the examination.

A Guthrie Lecture on Refractory Patients.

AT a meeting of the Guthrie Society, held at the Westminster Hospital, under the presidency of Dr. Murrell, on Thurdsay, February 25th, Captain Alfred Hutton, the well-known fencer and author of the "Sword and the Centuries," gave a demonstration of the methods of dealing with violent and refractory patients. The chairman pointed out that many medical men, especially those engaged in lunacy practice, were subject to attack by dangerous and irresponsible patients, whom it was desirable to disarm without inflicting on them bodily injury. The subject was not systematically taught in the schools, and every man had, on the spur of the moment, to act on his own initiative. There were certain recognised methods of procedure in such cases, some of which were of Japanese origin, and there was no one in this country who had a larger experience of them than Captain Hutton. Yukio Tani's locks, various knock-out blows, the forcible removal of resisting people, and other methods were demonstrated on members of the Society, and the proceedings concluded with a vote of thanks to the lecturer. It is probable that this new departure in the field of physical instruction will be followed by other medical schools.

Institute of Medical Sciences Appeal—University of London.

THE following additional promises of support have been received:—Alfred Beit, Esq., £5,000; H. T. Butlin, Esq., F.R.C.S., £1,000; Messrs. Rothschild and Sons, £500; J. K. Fowler, Esq., M.A., M.D., £250; Sir William S. Church, Bart, K.C.B., President Royal College of Physicians, £105; John Tweedy, Esq., President Royal College of Surgeons, £100; Sir Henry Roscoe, F.R.S., £100; Sir E. Cooper Perry, M.D., £100; E. Lauriston Shaw, Esq., M.D., £105; H. J. Chinnery, Esq., £100; George Raphael, Esq., £100; Charles Maw, Esq., £105; A. Pearce Gould, Esq., F.R.C.S., £100; F. Goodhart, Esq., M.D., £100; Sir R. Douglas Powell, Bart., M.D., £50; P. Frank, Esq., M.D., £50; C. R. Lockwood, Esq., F.R.C.S., £50; Sir Charles Metcalfe, K.C.M.G., £25. A large sum is needed to carry out the scheme. Donations, which may be extended over a period of three years, should be sent to the hon. treasurers, J. K. Fowler, M.A., M.D., Member of the Senate, and H. T. Butlin, F.R.C.S., Dean of the Faculty of Medicine, at 35, Clarges Street, W.

PASS LISTS.

Royal College of Surgeons in England.

THE following candidates, having passed the necessary examinations, have been admitted members of the College:—

Messrs. P. E. H. Adams, B.A.Oxon, R. Appleton, L.S.A.Lond., E. L. Ash, L. D. Bailey, H. H. Bashford, H. E. Batten, A. V. Benson, W. B. Billinghurst, B.A.Oxon, H. J. D. Birkett, B.A.Camb., A. J. Blaxland, L. H. H. Boys, H. R. Burpitt, Christopher A. Campbell, B.A., M.B.Toronto, Colin A. Campbell, M.D.Toronto, L.S.A.London, N. C. Carver, J. H. Chauncy, A. A. F. Clarke, G. R. H. Chell, J. W. Cleveland, G. M. Clowes, P. P. Cole, L.D.S.Eng., J. B. Copland, C. M. L. Cowper, T. W. W. Crawford, M.D.West. Univ., Canada, M. J. Cromie, S. T. Crump, A. Davidson, M.D.McGill. G. B. Davis, M.A.Camb., J. J. Davis, M.D. West. Univ, Ontario, A. C. Dixon, T. L. Drapes, B.A.Camb., G. D. Drury, A. G. V. Elder, J. W. Elliott, L.S.A.Lond., H. H. Elworthy, H. H. Royal College of Surgeons in Ireland.

DENTAL EXAMINATION.—The following candidates, having passed the secondary examination, have been admitted Licentiates in Dental Surgery of the College:—Mr. C. de Foubert and Mr. H. D. Griffith. The following candidate passed the primary part of the examination:—Mr. W. Matthews.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

M. R. C. S.—The commonest cause of post-partum hæmorrhage is uterine atony. That condition, however, should not occur in ordinary cases treated by expression of the placenta and the subcutaneous injection of ergotin. The next common cause is laceration of the cervix. If the tear extends into the uterine tissue proper and involve deep vessels, it may prove a formidable matter. In all cases the placenta should be promptly delivered. Some authorities recommend bimanual pressure, so conducted as to force the contracted uterus low down in the pelvis.

DR. W. M.—The notice was in type ready for our last issue, but owing to pressure upon our space was held over. We hope to insert it at an early date.

IRISH BRANCH BRIT. DENTAL ASSOC.—Your letter was sent to the wrong office, and consequently was too late to appear in the present issue. It will appear next week.

OUR PARIS CORRESPONDENT.—The receipt of the Clinical Lecture, by Professor Debove, on "Cancer of the Bile-Ducts" is hereby acknowledged with thanks.

DR. C. ROBERTSON (Birmingham).—Your observation is interesting. As a matter of fact many of the laity think that cold is a part of the "open-air" treatment, whereas, in point of fact, it is nothing of the kind. Clearly, warm clothing is especially required for all depressed conditions of general health and circulation.

W. B. COMPTON.—Common ink is an old remedy for ring worm. We cannot speak from experience, but should imagine its efficacy would not extend beyond the megalo-sporon variety, which is readily scotched. It is extremely unlikely that ink would be of the least use in the common microsporon form.

DR. VINCENT (Algiers).—We have marked your paper on "Cancer of the Rectum and Sigmoid Flexure" for early insertion.

MR. WILSON will find the subject exhaustively dealt with in our issue for February 17th.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 9th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Pathological Evening. Exhibition of Specimens.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street Cavendish Square, W.).—5.15 p.m. Demonstration of Cases of Interest.

SOUTH-WEST LONDON MEDICAL SOCIETY (Bolingbroke Hospital, Wandsworth Common).—8.45 p.m. Dr. R. Maguire: The Treatment of Aneurysm by Gelatin Injections.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. A. W. M. Robson: The Surgery of the Pancreas. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. M. Collier: Clinique. (Surgical.) 5.15 p.m. Mr. G. Ogilvie: What is Syphilitic?

THURSDAY, MARCH 10th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Papers:—Mr. L. Evans: The Treatment of Congenital Club-foot during early Infancy, with a Series of Consecutive Cases.—Dr. S. V. Pearson: The Diagnosis of Pulmonary Tuberculosis in Infants and Young Children.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—9 p.m. Clinical Evening. Cases will be shown by Mr. J. B. Lunn, Mr. H. Grimsdale, Mr. A. H. Bennett, Mr. H. L. Eason, and Mr. C. Worth. Patients will be in attendance at 8 p.m.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. G. Atkins, Dr. W. Duncan, Dr. I. Parsons, and Mr. F. Jordan. Paper:—Dr. D. Buxton: The Vernon Harcourt Chloroform Inhaler, and Exact Percentage Vapours of Chloroform in Surgical Anæsthesia.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pall Mall East).—5 p.m. Dr. R. Hutchinson: Some Disorders of the Blood and Blood-forming Organs in Early Life. (Goulstonian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. P. Stewart: Cranial nerve Paralyses.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—2.30 p.m. Mr. R. Lake: Demonstrations on Laryngeal Tubercular Cases. (I.) (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6.15 p.m. Dr. M. Dockrell: Herpetic Diseases. (Chesterfield Lecture.)

FRIDAY, MARCH 11th.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9 Adelphi Terrace, Strand, W.C.).—7.30 p.m. Paper: Dr. C. K. Millard: The Leicester Method of dealing with Small-pox. To be followed by discussion.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Dr. P. Weber and Dr. J. H. Watson: A Case of Polycythæmia with Enlarged Spleen, possibly a Disease of the Bone-Marrow.—Dr. Pasteur and Mr. T. H. Kellock: Foreign Body impacted in Bronchus: Removal by Operation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. A. W. M. Robson: The Surgery of the Pancreas. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. StClair Thomson: Clinique. (Throat.)

Vacancies.

Ayr District Asylum.—Assistant Medical Officer. Salary £120 per annum, with board, furnished apartments, attendance, and washing. Applications to the Medical Superintendent.

Birkenhead Borough Hospital.—Senior House Surgeon (Resident). Salary £100 per annum and fees. Applications to the Honorary Secretary.

Birmingham General Dispensary.—Resident Surgeon. Salary £150 per annum, with furnished rooms, fire, lights, and attendance. Applications to Ernest W. Forrest, Secretary.

Birmingham and Midland Eye Hospital.—House Surgeon. Salary £75 per annum, with board and attendance. Applications to the Secretary, Secretary's Office, Church Street, Birmingham.

Brentford Union.—Medical Superintendent of Infirmary and Medical Officer of Workhouse and Schools. Salary £300 per annum, with furnished residence in the Infirmary, rations, washing, &c. Applications to William Stephens, Union Offices, Isleworth, W.

Cumberland Infirmary, Carlisle.—Resident Medical Officer. Salary £80 per annum, with board, lodging, and washing. Applications to J. G. Howitt, Secretary.

Devonshire Hospital, Buxton, Derbyshire.—Matron. Salary £80 per annum, with board, lodging, and laundry. Applications to the Secretary.

Horton Infirmary, Banbury.—House Surgeon. Salary £80 per annum, with board and residence in the Infirmary. Applications to the Honorary Secretary, 21 Marlborough Road, Banbury.

Kent and Canterbury Hospital.—House Surgeon. Salary £90 a year, with board and lodging. Applications to the Secretary.

London Fever Hospital, Islington, N.—Assistant to the Resident Medical Officer. Salary £120 a year, with board and lodging. Applications to the Secretary.

Manchester Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to W. L. Saunder.

Mercers Hospital, Dublin.—House Surgeon. Applications to John Robinson, Registrar. (See Advt.)

Wolverhampton and Staffordshire General Hospital.—Assistant House Surgeon. Salary £75 per annum, with board, lodging, and washing. Applications to Edmund Forster, House Governor and Secretary.

Appointments.

ASHDOWN, WALLACE, F.R.C.S.Eng., Assistant Surgeon to the Metropolitan Hospital, Kingsland Road, N.E.

BENNETT, H. S., M.R.C.S., L.R.C.P.Lond., House Surgeon to the Out-Patient Department at St. Thomas's Hospital.

CLIFT, M. L., M.R.C.S.Eng., L.S.A., Divisional Surgeon to the City Road Station, G Division Metropolitan Police.

HARNETT, W. L., M.B., B.C.Cantab., Resident House Surgeon to St. Thomas's Hospital.

KEYSER, CHAS. R., F.R.C.S.Eng., Surgical Registrar to the Cancer Hospital.

POUNDEN, J. C., M.D.Dub., Certifying Surgeon under the Factory Act for the Alfreton District of the county of Derby.

RICHMOND, G. E., M.D. B.S., B.Sc Lond., D.P.H.Camb. Demonstrator of Hygiene and Public Health at University College, London.

SEARS, C. N. M.B., B.S.Lond., Junior Obstetric House Physician to St. Thomas's Hospital.

WIGRAM, L. E., M.B., B.C.Cantab., Resident House Surgeon to St. Thomas's Hospital.

Births.

HUBERT.—On March 5th, at Bromsgrove, Billingshurst, Sussex, the wife of W. A. Hubert, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

NOWLAN.—On March 1st, at Balbriggan, the wife of F. B. Nowlan, M.B. B.C.H., B.A.O., of a son.

Deaths.

CHEYNE.—On March 6th, at Edgefield, West Norwood, London, Mary Amelia Cheyne, wife of the late Robert Romley Cheyne, F.R.C.S., London, in the 86th year of her age.

KENT.—On March 4th, at Carlton House, Ringwood, Hants, Herbert Arthur Kent, M.R.C.S.Eng., L.R.C.P.Lond., fourth son of the Rev. Geo. Davies Kent, B.D., aged 44 years.

LEAH.—On March 3rd, William Leah, B.A.Oxon, M.D.T.C.D., of Teignmouth, Devon, aged 57.

SMITH.—On March 5th at Bridger, Montana, U.S.A., Henry Murray, only son of Dr. Stanley Smith, of Wimpole Street, London, aged 23.

SUTTON.—On March 1st, at 6 Camden Crescent, Dover, William Sutton, Esq., M.D., aged 77 years.

WAYLEN.—On February 29th, at 20 Beaumont Street, W., Louisa, widow of Alfred Robert Waylen, M.D., F.R.C.S.

Original Communications.

A FEW POINTS CONCERNING INGUINAL TRUSSES AND THEIR MANUFACTURE. (a)

By W. McADAM ECCLES, M.S.Lond., F.R.C.S.Eng.,

Assistant Surgeon to, and Joint Lecturer on Anatomy at, St. Bartholomew's Hospital; Examiner in Anatomy to the Society of Apothecaries; late Assistant Surgeon to the City of London Truss Society and to the West London Hospital.

MR. PRESIDENT AND GENTLEMEN,—I scarcely like to appear before this Society with such a subject for my theme, but ours is a liberal society, and our energetic secretary assures me that such a subject is not only permissible, but that it is one that will not be without its interest to the members of this vigorous young Society.

I have chosen the matter of the manufacture of trusses chiefly because I am deeply interested in it, and partly because I feel very strongly that everyone who prescribes the wearing of a truss ought to be sufficiently acquainted with the principles and essential details of its manufacture in order that he may know a good truss from a bad one. And this I say, for in spite of the fact that we treat hernia so largely by operation in the present day, there still remains a considerable number of persons who are obliged from one cause and another to fall back upon an external support. It is to them that the proper construction and adjustment of a truss constitutes all the difference between comfort and distress, security and danger.

It is not my intention to embark upon a description of all, or even of many, of the varieties of instruments which have from time to time been invented, my allotted length of paper and your patience would not permit. Suffice it, therefore, to say that the application of trusses is of very remote origin, but it is interesting to observe that Hippocrates, whose works abound in precise details, says nothing, so far as I am aware, concerning such appliances. Probably one of the earliest extant indications of external support is to be found on a small statue representing one of the minor deities of Egyptian mythology. Alas! that even the gods suffered thus! How much more mere mortal man!

I would premise my remarks by stating that I consider for most forms of hernial protrusions the best variety of truss is one which conforms to a type having a pad to cover the aperture, placed upon a spring which encircles the trunk, and accessory straps for better support. This would seem but a simple affair for any practical instrument-maker to fashion, yet, believe me, the pitfalls into which the mechanician may stumble in its construction are many and serious.

Let us take as a type an ordinary inguinal truss. Let us consider a well-made and a badly-fashioned example. I would lay down the following as the essentials of a well-made ordinary inguinal truss:—

1. The *pad* has its foundation of soft iron. This should be somewhat oval in shape, with two studs on its anterior surface, and two sharp points on its posterior aspect. The size of an inguinal pad for an adult is about four inches long, two inches broad, and one and a half inches thick when its facing of cork is in position, and held there by the points. The lower border of the pad, which is curved, should project only half an inch below the inferior edge of the spring. It is of great importance that it should not descend further than this, for if it does there will be a tendency for the pad to become displaced upwards by the movements of the thigh. The pad should as a rule be solid, and fixed immovably to the spring by rivets.

2. The *spring*. The function of the spring is to induce pressure, such pressure to act as a counter-pressure to the normal or abnormal intra-abdominal pressure. The external pressure as projected by the spring is capable of interpretation in two ways, first, the resilient, and secondly, the resistent, the former being much more pliable than the latter.

The resilient pressure should only come into play in preventing the descent of viscera in a bubonocele both while the patient is quiet and when he has to exert some increased amount of abdominal strain. The resistent is needed when resilient pressure is not sufficient to retain the viscera in the periods of quietude or where the patient is liable to excessive strain by reason of his occupation, &c. It is therefore not correct to use the resilient form of pressure where the resistent is needed, and it is still more improper to apply the resistent variety where only the resilient is required.

In order that a spring may act efficiently, and at the same time may be comfortable, there are several essential points in its manufacture, which are unfortunately frequently not understood by truss-makers, or at least overlooked by them. In a single truss there have to be considered the following—the length, the breadth, the curve, the temper, and the free end of the spring.

I am confident that the spring in a single truss should be more than a semicircle—that is to say, it should pass round the pelvis and reach to just behind the anterior superior iliac spine of the sound side. From this point the coverings of the spring are prolonged as a cross-strap, which is fastened to the upper stud on the face of the pad. The breadth of the spring is likewise of importance. If too broad, it will be too powerful, if too narrow, it will tend to cut into the tissues of the wearer. As a rule half an inch or a trifle more is the best breadth. The curve of the spring is where not infrequently failure is to be noticed. It should be such that the pad is on a plane only slightly posterior to that of the anterior portion of the spring. It, as is the case in some badly-fashioned trusses, the curve is so great as to make the pad almost touch the hinder part of the spring, the pressure that will be exerted by it will be so severe that the patient will not be able to endure it. Further, the temper of the steel from which the spring is cut should be brought to such a nicety that it will allow a very considerable opening out of the curve without the least liability of the metal snapping.

In order that the spring may rest flat upon the body, the lower edge of it must be the arc of a larger circle

(a) Paper read at a meeting of the Therapeutical Society, on February 23rd, 1904.

than the upper edge, owing to the increasing circumference of the pelvis against which the spring is applied. If this were not so, it would naturally follow that the truss would only rest upon its lower edge, and would consequently be exceedingly uncomfortable. It is astonishing how seldom this practical point is carried out in the manufacture of trusses, and yet it is one of the most important, if a comfortable instrument is to be provided.

And, lastly, the termination of the spring should in the process of manufacture be hammered out so that it becomes thin and flat, and therefore much more flexible than the rest of its length, and thus likely to cling steadily around the hip opposite to the side on which the hernial protrusion exists. This little, but important, point is one of the many ways in which a poorly-fashioned and cheap truss can be readily distinguished from a well-made one. The spring has to be covered with soft material, partly to protect it, and partly to render its application to the patient's body a source of the least discomfort. There is always a great tendency for the metal of the spring to rust owing to the action of the moisture from the body, and it is desirable to cover it with some material which will prevent this as far as possible. Nothing has up to the present been found which is entirely satisfactory. Neither has any form of plating been of complete service.

Immediately next the steel comes a layer of what is known in the trade as "glaze," a material which does in some measure prevent the moisture of the body from reaching the metal. Outside this, there should be two layers of "blanketing," which act in making the spring comfortable to the wearer, and upon the thickness of it within reasonable limits depends its value. Many badly-made trusses are wanting in a sufficiently thick layer of this material, in fact, may have none of it whatsoever. External to these coverings is placed one of "flesh," not ordinary chamois leather, and posteriorly for support and protection is a layer of calf leather.

For bathing purposes the spring should be covered with gum-elastic, or pure indiarubber, and the former is a useful covering for use in hot climates, or where the wearer's occupation induces much perspiration.

3. The *under-strap*. Every inguinal truss should be provided with an under-strap, and the wearer should look upon it as an essential part of his instrument.

It is of practical utility in preventing the spring from riding up over the hip bone, in securing the position of the pad from change, and in giving this latter a slight tilt at its lower edge so that it will face a little upwards. The proper adjustment of the under-strap is all important, for if it be incorrectly applied it is worse than useless. It should be fixed just behind the shoulder of the truss—*i.e.*, to that part of the spring which is directly behind the anterior superior spine of the ilium on the same side as the hernia. It must be so fastened that it will not of itself have any tendency to shift its position. This can be accomplished by a very simple manœuvre of placing the strap on the inner side of the spring and threading the end through the loop held on the outer side near the shoulder of the truss.

The under-strap is then carried downwards and backwards along the gluteal fold, across the perinæum, and upwards to fasten in front to the lower stud on the front of the pad. It is not to be applied tightly, but is to be well drawn upon, whilst it is being fixed in position. Often the under strap is placed by the patient or instrument-maker at or near the middle line behind, where it cannot by any possible chance fulfil its functions, but only serves to irritate and worry the wearer. Many patients on this account discard the under-strap, considering it of no value, which is true, but are delighted to find the added comfort it gives if correctly adjusted.

I would, therefore, sum up a good ordinary inguinal truss as one in which there is a solid pad of the proper shape and size, fixed immovably upon a steel spring encircling three-quarters of the circumference of the pelvis, and held in position by properly adjusted under- and cross-straps.

The spring is to have its lower border the arc of a larger circle than the upper edge, and its curve such that the pressure which it exerts is moderate in every case, resilient in most, and somewhat resistent in others, while its termination is so hammered out that it is beautifully flexible.

If a patient is provided with a truss of this character, and his medical attendant should see to it that he is, he will come to look upon his instrument as little more than part of his ordinary clothing, and as giving him less inconvenience even than his boots! On the other hand an incorrectly fashioned appliance may entail daily and hourly misery, which is sure to be unwittingly placed to the credit of the practitioner's prescription rather than to the ignorance of the instrument-maker.

If I have not already wearied you with what I fear may seem somewhat trifling matters, though in truth to me they are of essential importance, I would venture to call your attention to two more elaborate and highly useful forms of an inguinal truss.

The first is the rat-tail truss. Its use is specially seen in scrotal herniæ in elderly men. As a rule these patients are wholly unsuitable for any radical operative procedures, and their protrusions often fail to be controlled by an ordinary inguinal truss, even with a resistent pressure. Here, again, there may be all the difference between comfort and efficiency, and misery and danger, solely on account of the proper construction and adjustment, or the improper conformation and application of a rat-tail truss.

In a well-made instrument of this pattern the pad is somewhat fuller than in the ordinary inguinal truss, and there is the addition of a tapering piece of soft material springing from the lower part of the pad, and prolonged into a strap which takes the place of the usual under-strap, and it is fastened to an immovable hook or buckle just behind the shoulder of the truss. It is very important that the iron of the pad should not pass down into the tail, for if it does so the soft parts, and particularly the spermatic cord, must necessarily be compressed between the metal and the bone, since the tail occupies a position over the superficial ring and the crest and the body of the os pubis. This prolongation of the pad metal into the tail of the truss is frequently seen in badly-constructed instruments and is much to be deprecated, as is also the use of a movable buckle, to which the termination of the tail is attached. Seeing that in the upright position the rings and the canal, particularly in a stout patient whose abdomen tends to sag downwards and forwards, assume a rather more horizontal plane, it is well that the face of the pad should look upwards so that pressure may be brought to bear directly over the hernial aperture, while at the same time the spring rests comfortably against the abdominal wall outside the site of the hernia. This can be brought about by slightly cranking the steel of the spring just external to the place where the pad is rivetted to it. If, on the other hand, the pad is flat, the iron of the pad prolonged down into the tail, the pad maintained on the same plane as the rest of the spring immediately external to it, and the termination of the tail fastened to a movable buckle, not one of the essential features of a proper rat-tail truss will be obtained. Yet by far the larger proportion of such trusses are made by instrument-makers in this improper fashion, and it is only necessary to scan the illustrations of their catalogues to see the truth of this statement.

The last variety of truss that I submit to you is one which is of the greatest service in the treatment of irreducible scrotal herniæ. One is often consulted as to the best manner of dealing with irreducible scrotal herniæ in elderly and stout persons. Operative measures are out of the question in almost all. The application of an ordinary bag truss is merely to court danger, and cannot have the least effect in bringing about any reduction of the contents of the hernial sac.

It is under these conditions that I believe that the practitioner is often at a loss to know how best to treat

his cases. Here it is that the ingenious truss known as the hinged-cup inguinal truss comes in so usefully. It has been urged that pressure applied to an irreducible hernia is very liable to produce irritation of the contents and of the sac wall, and thus lead to complications other than those of mere non-reduction. Such untoward effects, however, do not in reality occur if the pressure is of the right amount and is employed in the correct manner. On the other hand, such proper pressure may be most beneficial in tending to the reduction of the contents of the sac. To do its work this pressure must be continuous and must be in a direction that is most likely to bring about the return of the imprisoned viscera into the abdominal cavity. The hinged-cup truss consists of the ordinary circular steel spring, so modified, however, as to meet the special requirements of the condition under review. To the front is attached a flattened pad, with what is known as the forked-tongue addition, and to the lower edge of the pad is fastened through the medium of a hinge an open triangular cup of metal, covered in the completed state with flesh leather. From the inferior angle of this cup there pass two leather straps, which act as perineal bands, and go to be fastened to movable buckles on the circle of the spring. The action of the truss is to exercise upward and backward pressure upon the irreducible contents lying in the scrotal part of the sac by the pull of the under-straps acting upon the hinge, which will only allow of movement in an upward and backward direction.

The results in the way of reduction obtained by this instrument are of a most satisfactory character, and it is desirable that the utility of the truss should be more widely recognised.

In conclusion, I trust, gentlemen, that you will not have thought me presumptuous in reminding you of some of the details of truss manufacture, apparently of but little importance in themselves, but in their sum total meaning a great deal to those who have the misfortune to need external assistance.

DR. OTTO SCHMIDT'S SPECIFIC TREATMENT OF CANCER :

A CRITIQUE BASED ON PERSONAL OBSERVATION.

By JOHN SHAW, M.D.Lond., M.R.C.P.Lond.,

Physician for Diseases of Women at the North-West London Hospital; late Vice-President of the British Gynæcological Society.

It was with intense interest that I heard of the address given by Dr. Jossé Johnson at the Abernethian Society, and determined to take the opportunity of a holiday in Switzerland to examine Dr. Otto Schmidt's cases, both on my way out and on my return, so as to be able to judge of what a month's treatment had done for the patients.

The dates of my two visits were December 16th, 1903, and January 11th, 1904, so that the actual interval was twenty-five days. I should, perhaps, explain that it was during this interval that I took the opportunity of reading Dr. Johnson's address, in order better to appreciate the matters which I desired to investigate.

On the occasion of my first visit, I saw three patients at the Augustiner Closter, and in the afternoon three other patients at the doctor's own home, of whom two were fellow-countrymen—one being a retired medical man.

On my second visit I went straight to the Augustiner Closter, in order that I might communicate with Dr. Schmidt and, if necessary, ask to see Mrs. H——, in his absence, as I had been informed that this lady, one of the cases reported by Dr. Johnson, was that day to leave for home, completely cured of the cancerous process. Dr. Schmidt was, however, as I learnt by telephone, already on his way to the Closter. He was, therefore, not expecting me, but nevertheless kindly showed me three patients and, further, unasked, invited me to visit his laboratory in the evening.

The English patients who visited his house in the afternoon were, however, so eagerly desirous that I should accompany them that the necessary permission was applied for by telephone, and thus I had the further opportunity of renewing acquaintance with a patient whom I had seen on the occasion of my first visit.

In the evening I had the pleasure of seeing Dr. Schmidt's new laboratory, a visit which gave me a good deal to think about, but as I have dealt elsewhere with some of my difficulties, it may be preferable to confine myself in this paper to the clinical cases, short particulars of which follow.

Case 1.—I will refer in the first place to the Mrs. H——, reported by Dr. Johnson. (*a*) At my first visit, this lady presented the appearance fairly described by Dr. Johnson, excepting that I was unable to detect any diminution of the frontal swelling as compared with a photograph taken a fortnight before her admission under Dr. Otto Schmidt's care. Moreover, there was a central excavation in the frontal growth going down nearly to (if not actually reaching) the bone, which excavation was being treated by dressings with the very strong solution (Merck and Co.'s) of hydrogen peroxide.

It will be important to quote certain passages from Dr. Johnson's report, merely mentioning that I took no measurements for the purpose of comparison :—

"On July 1st, the last operation wound was not yet closed ; there was no local recurrence and no glandular infections were to be found. On the upper right forehead there was a smooth, hard, evenly rounded swelling, three and a half inches long sagittally, two and a half inches broad, and rising to a height of five centimetres (that is to say, two inches) above the surrounding scalp, measured vertically. The consistence was everywhere equally hard like a fibroid. The colour over the skin was natural. Further behind and to the left there was another knot of the size of a broad bean. . . . When I saw the forehead tumour for the first time, it was about one-third bigger than when I saw it for the last time on Friday, October 30th. It had steadily decreased the whole time, and the patient herself was perfectly well except for the pain in the arm. She was cheerful and putting on flesh, and was going on as well as any patient could wish to."

It was my interest in this patient that took me to the Augustiner Closter on January 11th, having understood that she was that day to be discharged *perfectly cured of the cancerous process.*

Dr. Schmidt assured the patient and myself that sections of the growth evidenced the cessation of the carcinomatous condition, although he admitted that she still had some febrile reaction after injections. The forehead tumour showed, in my judgment, considerable increase in superficies, although it may have slightly diminished in height owing to the extensive degeneration and undermining which was taking place. It was breaking down in at least two other spots. It was marked by enlarged and somewhat tortuous veins, a sign of malignant *activity*, but which I was assured was an evidence of its quieting down. The second swelling was, in my estimation, at least double the size, and there was an enlarged gland of considerable size behind the right ear. My offer to take a photograph of the patient was declined. This patient had been seven months or so under treatment ; had had about one hundred and fifty injections ; was acknowledged to have lost flesh (although her weight, it was said, had not been taken during the whole course of the seven months), the loss of flesh being ascribed to the feverish reaction from the injections.

The patient was going home with the cancerous process arrested ! Hearing that her home was beyond Berlin, I asked if Professor von Bergmann had given any opinion as to the arrest of the cancerous process, and was assured by the old formula with which I shall

(*a*) *Lancet*, November 14th, 1903. P. 1376.

always associate Dr. Schmidt: "Es hat keinen Zweck."

On the other side, it must be remembered that it is alleged that von Bergmann had given a prognosis of but two months *if he operated*, and that the patient was seven months later not only living, but was showing remarkably little facial evidence of all that she had gone through—a circumstance which is not unknown in patients who have not undergone any serum treatment, but who are rapidly nearing the term of their sufferings.

Case 2 was that of a poor lady who had come from Russia in the hope of finding relief, buoyed up, it may be, by Dr. Johnson's words: "Dr. Schmidt's experience, when treating absolutely inoperable cases—and he has had no others—is so favourable that he would not hesitate to use it in all these seemingly hopeless cases." She was frightfully ill when I saw her, and shortly after died. Dr. Johnson has since assured the writer that the patient was under Dr. Schmidt's treatment before his paper was published, so that the patient must have succumbed after she had been under treatment for a very considerable time.

Case 3 was that of a lady who had had her breast amputated by Dr. Schmidt. As I saw her on the occasion of my first visit, she had a largish open wound, where an incision had been made to relieve the tension on the cicatrix, and pus was issuing from a drainage-tube in the axilla. At my second visit, this lady came for treatment, but Dr. Schmidt explained that there was no reason why I need see her ("Es hat keinen Zweck"), the rise of temperature reaction indicating that there must be still some infected gland which he had failed to remove.

Whilst this patient's wound was being dressed, we waited outside in the corridor, and Dr. Schmidt explained that he had first injected culture and got a violent reaction, during the continuance of which he had operated, whereupon the temperature had fallen as markedly as if an abscess had been opened.

Case 4 was seen on my second visit to the Closter, and is reported by Dr. Johnson on page 1,377 of the *Lancet*, November 14th, 1903. The appearance of this patient came as a shock to me. She was thin and very pale, though there was a flush on her cheeks, and she was quite cheerful. Dr. Schmidt repeatedly drew my attention to the fact that she could put up her left hand to the back of her neck or head, which she had been unable to do before the treatment, and with this accomplishment the patient seemed very gratified. With regard to the left breast, I really am perfectly puzzled. It may still be cancerous or it may have passed into the cirrhotic and innocuous condition described. Immediately below the breast, however, there is what I certainly believe to be cancerous involvements of the skin. Moreover, the left elbow and parts immediately above were very markedly œdematous.

But there is one very remarkable circumstance about this case. There had developed in the right breast a cancerous tumour, which *has been removed by operation*, although the inoperable cancer of the left breast is claimed as a success without operation.

Case 5 was a gentleman suffering from a large swelling below the right ramus of the lower jaw. The swelling was said to be of the nature of an embryonic remnant, and to have wonderfully improved under treatment, Dr. Schmidt's statement being borne out by the patient. A month later, as I saw him for the second time, the swelling had very greatly increased, and the patient was so hoarse that I had the greatest difficulty in understanding him. I learnt from Dr. Schmidt, and the patient nodded his assent, that he, the patient, had been hoarse on a former occasion, and that the swelling had been even greater than that which I was at the time witnessing. In answer to my inquiry as to whether there was any paralysis of the vocal cords, I was informed that Dr. Schmidt had not himself examined the case, but that Dr. Johnson had done so, and had reported that the right cord was pushed over by the growth, and was very congested, but that there was no paralysis.

Case 6 can be dismissed in a few words. It is one of cancer beneath the tongue with involvement of the glands on both sides. In comparing the condition as seen at the two visits, I should say that the swelling is about doubled in bulk, and is said to have become somewhat painful, that there is increasing disability to project the tongue between the teeth, and that owing to this cause a slight lisp has become noticeable to the patient and to myself, although so little marked as not to have attracted the attention of relatives.

Case 7 is that of an English gentleman, æt. 55, and. excepting for gout and other tendencies to chronic inflammatory processes, was quite well until September, 1902, since which time he has suffered from enlarged glands in the neck, with recurrent attacks of sore throat, but has not lost weight. In consequence of the absence of the inflammatory reaction which is said to be diagnostic of cancer, the patient and his English medical attendant felt justified in doubting the accuracy of the previous diagnosis, to which, however Dr. Schmidt clung, claiming that the absence of the diagnostic reaction was due to the fact that he had purposely avoided the reaction by giving very minute doses. In comparing, however, the figures entered by Dr. Schmidt's assistant in the patient's temperature record with those quoted by Dr. Johnson as the routine practice, I find that they are *absolutely identical*, and, indeed, exceed those given to the Mrs. H——, to whom both Dr. Johnson and I refer. I may say that this patient came back to London, in order to see an eminent cancer specialist, and returned to his home enjoying a peace of mind to which for many weeks previously he had been a stranger.

Unfortunately, the history of this patient does not end thus. I am informed that malignant mischief of undoubted character has developed. What am I to conclude?

That he had had cancer, and that Schmidt's treatment had checked or temporarily cured it? I cannot accept this position, for the following, among other reasons:—(1) The patient's throat trouble dated from September, 1902, since which time he has never lost the enlarged glands. Can any member of the profession point to a single case of undoubted cancer of the tongue which lasted fourteen months without treatment, the patient in the meanwhile having maintained his weight? (2) The patient was seen on the morning of November 17th, 1903, by a very well-known man who himself is strongly interested in cancer, and there was no suspicion then of the condition being cancerous; indeed, this medical man has expressed himself as unable to accept the position, seeing that he recorded the pulse as but 64. He prescribed tinct. benz. co., and with this the patient thoroughly steamed his throat before getting into bed. A few minutes after lying down, he (the patient) was taken with a severe choking sensation, immediately sat up and vomited a quantity of "blood, and phlegm, and stuff," after which he felt great relief and slept all night. Is this the history of cancer? (3) Ten days after this (November 27th, 1903), the patient having in the meanwhile gone to Cologne, he received from Dr. Schmidt his first injection, $^1/_{100}$ milligramme of culture, and on the following day $^1/_{10}$ milligramme. The next day was Sunday, and the patient felt his throat well, a fact which was, the patient alleges, confirmed by Dr. Schmidt on the following Thursday, there having been no laryngoscope available before that date for the examination; in the meanwhile, therefore, he had had three more injections, the last being 2½ milligrammes. My first visit to Cologne was on December 16th, 1903, and I took down from the patient the following note:—"December 3rd. Throat was examined and found to be quite well; [absolutely completely healed over]." The inverted brackets are the alleged words of Dr. Otto Schmidt, who later assured me that he himself had never seen an ulcer in the patient's throat. (4) There is the very important consideration that side by side with this doubtful

case was a case of undoubted malignant mischief (*Case* 6 above), which, to the best of my belief—a belief which is shared by one whose interest is to believe quite otherwise—there has been absolutely no improvement whatever; it is the case referred to in the leading article in The Medical Press and Circular for February 17th, 1904.

The serious question is this, had this patient malignant disease before he was treated by Dr. Schmidt? I have given the chief reasons which would guide me to an opinion. It is to be noted that immediately before leaving Cologne he had had three injections of what was alleged to be a very virulent culture, in doses of 10, 20, and 30 milligrammes respectively; that is to say, 1,000, 2,000, and 3,000 times as large a dose respectively as that with which the treatment commenced. Now, supposing that this patient at the present time has malignant disease (which I will hope is non-proven), the serious question is, has it been produced by the injections of these alleged cultures? To me the position is such a serious one that I shall continue to urge an immediate discussion before a suitable medical society, an effort in which, up to the present, I have not succeeded.

THE TREATMENT OF CHRONIC MIDDLE-EAR DEAFNESS BY OZONE.

By GEORGE STOKER, M.R.C.P.I.,

Consulting and Hon. Physician, London Hospital for Diseases of the Throat, Nose, and Ear; Hon. Medical Officer to the Oxygen Hospital.

The form of deafness to which the present paper refers is that popularly known as throat deafness, and to the medical profession as "chronic dry catarrh of the middle ear."

It is generally believed to be due to stenosis of the Eustachian tube. This latter condition may be brought about by some interference with nasal respiration, the result of congenital malformation, or chronic nasal catarrh.

The symptoms are progressive deafness, with tinnitus of various kinds and varying intensity. It is also to be noticed that in a large number of cases the hearing is comparatively more defective in reference to sounds close at hand than to those at a distance. The condition is analogous to what is known as presbyopia in defects of sight, and I venture to describe it as presbyaudia. The best illustration I know is that of a patient, who, while conversing in a room with friends, found a difficulty in hearing those near him, but was able to detect the approach of a carriage to the house before the others heard it. This condition is possibly the result of some loss of power of accommodation in the muscles, due to the thickening of the mucous membrane covering them.

The tympanic membrane is retracted and usually opaque. There are no signs or symptoms of the auditory nerve being involved. Of all forms of deafness this is the most common and the most intractable, and it is no exaggeration to describe it as the opprobrium of otology.

It would seem that stenosis of the Eustachian tube must affect the mucous membrane lining the middle ear—

(*a*) By preventing the free ingress and exit of air.

(*b*) By causing an unhealthy condition of the secretions that exude from the lining of the cavity and preventing their exit.

These conditions lead to a thickening of the mucous membrane of the tympanum and consequent deafness.

The nasal stenosis may be relieved, and the Eustachian tube become more open, but the deafness still increases; this points to a *remaining* unhealthy condition of the middle ear.

The effect of oxygen, and more particularly of its allotropic form, ozone, in restoring a healthy condition to diseased nasal mucous membrane, and in purifying the secretions, suggested a trial of the latter in chronic progressive deafness.

The ozone is generated by means of an electric current acting on a Ruhmkorff coil, to which the ozonising tube is attached. The ozone is passed in a gentle current through a Eustachian catheter into the middle ear for about four minutes at a time, the operation being repeated several times a week, daily, if possible.

The following are notes of cases treated, the conditions first described being those existing before the ozone was applied. They were nearly all cases of "chronic dry catarrh" of the middle ear, accompanied by the usual symptoms.

Some of them had been previously treated by various methods, for considerable periods.

Case 1.—Patient had been getting deaf for ten years. There was "hissing" tinnitus, especially in the left ear. Before treatment.—Watch hearing: R. ear = 1½ in.; L. ear = contact. After two months' treatment.—Watch hearing: R. ear = 4 in.; L. ear = 3 in. After five months' interval without treatment.—Watch hearing: R. ear = 5 in.; L. ear = 3 in.

Case 2.—Deaf for many years. Before treatment.—Watch hearing: R. ear = 5 in.; L. ear = 3 in. After six weeks' treatment.—Watch hearing: R. ear = 12 in.; L. ear = 6 in.

Case 3.—Getting deaf for twelve years. Before treatment.—Watch hearing: R. ear = ½ in.; L. ear = 1 in. After six weeks' treatment.—Watch hearing: R. ear = 8 in.; L. ear = 3 in.

Case 4.—Getting deaf in right ear for three years. Before treatment.—Watch hearing: R. ear = 3 in.; L. ear = 20 in. After six weeks' treatment.—Watch hearing: R. ear = 9 in.; L. ear = 24 in.

Case 5.—This patient had chronic suppurative otitis media of the right ear, and chronic dry catarrh of the left ear, of old standing. Before treatment.—Watch hearing: R. ear = minus; L. ear = 6 in. After six weeks' treatment.—Watch hearing: R. ear = 3 in.; L. ear = 24 in.

Case 6.—This patient was deaf for fifteen years with buzzing tinnitus. Before treatment.—Watch hearing: R. ear = ½ in.; L. ear = minus. After six weeks' treatment.—Watch hearing: R. ear = 18 in.; L. ear = ¾ in.

Case 7.—This patient was deaf in the left ear for nine years. Before treatment.—Watch hearing: L. ear = ¼ in. After six weeks' treatment.—Watch hearing: L. ear = 4 in.

Case 8.—This was a case of deafness of nine years' standing with "tidal tinnitus." Before treatment.—Watch hearing: R. ear = contact; L. ear = ½ in. Tuning-fork hearing: R. ear = 3 in.; L. ear = 5 in. After six weeks' treatment.—Watch hearing: R. ear = 4 in.; L. ear = 1½ in. Tuning-fork hearing: R. ear = 2 ft.; L. ear = 2 ft.

Case 9.—This patient had been deaf for twelve years. Before treatment.—Watch hearing: R. ear = ½ in.; L. ear = ½ in. After six weeks' treatment.—Watch hearing: R. ear = 10 in.; L. ear = 10 in.

Case 10.—Patient was deaf in right ear for ten years with singing tinnitus. Before treatment.—Watch hearing: R. ear = ½ in. After six weeks' treatment.—Watch hearing: R. ear = 6 in.

Case 11.—In this case patient was deaf for five years with hissing tinnitus. Before treatment.—Watch hearing: R. ear = 1½ in.; L. ear = hard contact. Tuning fork hearing: R. ear = 6 in.; L. ear = 4 in. After two months' treatment—Watch hearing: R. ear = 3 in.; L. ear = 2 in. Tuning-fork hearing: R. ear = 2½ ft.; L. ear = 2 ft.

Case 12.—Patient had been deaf for twelve years with buzzing tinnitus. Before treatment.—Watch hearing: R. ear = 1 in.; L. ear = 1½ in. Tuning-fork hearing: R. ear = 2 in.; L. ear = 3 in. After six weeks' treatment.—Watch hearing: R ear = 7 in.; L. ear = 9 in. Tuning-fork hearing: R. ear = 2ft.; L. ear = 2 ft.

In all the above cases it will be seen that the hearing

has improved. In some, the progress made has been remarkable. The improvement, as shown by the watch, represents comparatively a very much greater degree of progress when the voice is in question. A patient with only one inch of watch hearing may be considered rather deaf, whereas with four inches of watch hearing the deafness is not by any means evident.

In cases of such a degree of deafness, of such long duration, the time during which the treatment was continued was far too short to produce the best results, and it is reasonable to suppose that if the treatment had been carried out daily, and for a longer period, the results would have been better still. Another favourable result achieved by this treatment is the disappearance of the distressing tinnitus that existed in nearly every case. In conclusion I would point out that, after all, there are two objects in treating such cases as are alluded to in this paper—first, to improve the hearing, and secondly, to prevent the deafness from becoming worse, and there is conclusive evidence that both these objects may be brought about by the use of ozone.

CHRONIC INTESTINAL OBSTRUCTION

CAUSED BY

ANNULAR STRICTURE (MALIGN) OF THE LARGE INTESTINE. (a)

By DAVID WALLACE, M.B.Ed., F.R.C.S.Ed.,
Assistant Surgeon, Edinburgh Royal Infirmary.

THE paper was based on ten cases of stricture of the large intestine (exclusive of the cæcum and rectum) operated on during the past year. In eight the cause of the stricture was ascertained to be malignant, while in two there had been every likelihood of a similar cause, though from the necessity of rapidly completing the operation it had not been definitely determined. By annular stricture was meant a cylindrical-celled epithelioma, resulting in a very hard ring-like formation transverse to the long axis of the bowel, and giving rise to an hour-glass constriction. The bulk of the tumour-growth is inside the bowel, the margins standing out abruptly from the mucous membrane, and greatly narrowing the lumen of the gut, so that in many cases the aperture will only admit of the passage of a crow-quill. Above the stricture the bowel is hypertrophied and dilated. Although for such a condition to have arisen considerable time must have elapsed since the tumour began, yet in most cases there is little discomfort other than constipation, requiring the use of purgatives. The higher the tumour the less likely are symptoms to become manifest, as the fluid contents of the bowel easily pass through a smaller orifice than the more solid fæces in the sigmoid and lower part of the colon. Owing to the insidious onset, chronic obstruction is often the first reason for the patient seeking medical advice—often too late for curative treatment. In six of his ten patients this had been the case, and as all were drawn from the better classes, it was reasonable to suppose that the delay in getting medical advice was not due to carelessness or disregard of symptoms, as might have been the case in hospital patients. The most common symptoms for which advice is sought prior to the onset of obstruction was constipation, and abdominal distension, and pain; occasionally there was loss of weight, and sometimes a tumour had been noticed. The latter, however, was rare, and even to the clinician a tumour could usually only be felt after the disease had extended beyond the wall of the bowel. In four out of his ten patients a tumour was to be felt before operation. In early stages the significance of constipation and abdominal pain was not readily recognisable, and we had to delay diagnosis until later indications arose, *viz.*, continuance of abdominal discomfort and constipation, distension and borborygmi, paroxysmal pain and visible peristalsis, loss of weight, a palpable tumour, and acute or chronic obstruction. The absence of these, however, did not exclude the possibility of stricture. Constipation was present in all his cases, alternating with diarrhœa in two, loss of weight in seven, distension and borborygmi in four, tumour in four, visible peristalsis in only two. Three other symptoms were usually mentioned: (1) Ballooning of the rectum, present in one case of stricture of the hepatic flexure; (2) change in the form of the stools, on which no reliance could be placed; and (3) passage of mucus and blood, which was also unimportant. In six patients obstruction was the symptom for which advice was sought; in none was there a palpable tumour, and in four an annular stricture without adhesions was present. In two other cases a tumour was detected at the first examination, and in two more at subsequent examination only; of the last, the symptoms were, in one instance, diarrhœa alternating with constipation and loss of weight; in the other, pain, constipation, and loss of weight. Six patients were females and four males, and the ages from 47 to 82 years. Five of the tumours were at the splenic flexure, three at the hepatic flexure, and two at the upper part of the sigmoid flexure. The anatomical relations of the two first-mentioned parts of the bowel explained the infrequency of palpable tumour. As to the diagnosis, Mr. Wallace pointed out that, given a case of chronic obstruction in a person of middle life, there being neither palpable tumour nor evidence of rectal neoplasm, annular stricture was most probable. Though each case had to be considered on its own merits, it was most important that such cases should not be treated medically for too long a time, and that the practitioner should recognise that the history of chronic constipation with abdominal pain was *prima facie* ground for suspecting annular stricture. The prospect of successful surgical treatment would be immensely enhanced if the patient could only be operated on at this stage, before invasion of adjacent tissues, or definite obstruction symptoms, had taken place. When a patient was seen in whom obstructive symptoms existed, it was usually justifiable to wait, provided these were not urgent, and first to try medical measures, watching the pulse, the degree of abdominal distension, and the general condition. If relief was obtained, the day was long past for being thankful and believing all was at an end; a second and more serious attack was inevitable—the justification for delay in the first instance was the desirability of operating during a quiescent period, the prospect of successful radical treatment being so much greater when the conditions were the most favourable possible, the chief *desideratum* being the emptiness of the intestines. It ought always to be explained to the patient that it may not be possible to remove the tumour, and that it may be necessary to make an artificial anus. Three operations are possible: (1) Excision and end-to-end anastomosis, (2) short

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, March 2nd, 1904.

circuiting, (3) colostomy. The incision, unless there was a definite contra-indication, ought to be made through the right rectus just missing the umbilicus, from which all sites of cancer could be explored, and if the growth was on the left, allowed of the transverse colon being opened, while if it was on the right an ileo-colostomy could be done. This incision should be made large enough at first; ventral hernia was not likely to result, and it was a favourable position for an artificial anus. If the tumour was removable, a second incision would probably be required. Colectomy, though the best operation, could seldom be performed primarily in obstruction cases. Usually all that could be done was to make an artificial anus, leaving the tumour outside the abdominal wall, and dealing with it later. For successful excision absence of tension on the stitches was of the first importance. The most favourable method of short circuiting was ileum to transverse colon. Here, again, absence of tension was essential, and emptying the bowel a great aid to a good result. After short circuiting, the tumour often diminished in size. Colostomy, the least desirable, was often the only admissible operation; he had adopted it in five cases, of which one died on the fifth day. The position of the artificial anus depended on the site of the tumour, but should be as far from the cæcum as possible, as the comfort of the patient depended greatly on the fæces being solid. The gut should be opened at the lowest part to avoid the risk of retention of fœtid fæcal matter in the bowel—a fertile source of toxæmia and heart failure. His results were :—Two colectomies, one patient living after thirteen months, one death on the fourth day from peritonitis; three ileo-colostomies with one death on the fifth day from giving way of stitches; four colotomies with one death.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, MARCH 11TH, 1904.
DR. FREDERICK TAYLOR, President, in the Chair.

DRS. F. PARKES WEBER and J. H. WATSON communicated a case of

CHRONIC POLYCYTHÆMIA WITH ENLARGED SPLEEN.

The patient was a cabinet-maker, æt. 58, who had previously been very ruddy in the face, but for the last six years a variable amount of cyanosis in the face and extremities had been noticeable. In 1903 he fractured some ribs, and afterwards commenced to have delusions of persecution. The peculiar symptom-complex of chronic cyanosis with splenomegaly and polycythæmia was observed at the German Hospital in the latter part of the same year. At Colney Hatch Asylum, to which he was removed, he remained bodily and mentally feeble, and during an attack of greatly increased cyanosis died suddenly on February 4th, 1904. The chief clinical features of the case were the chronic cyanosis, not to be accounted for by thoracic disease, the enlarged spleen, and the polycythæmia. The blood contained about double the normal amount of red cells, and the hæmoglobin value was about 170 per cent. of the normal. Extreme distension of the retinal vessels was observed. The urine was high-coloured. Asthenia was well marked. The post-mortem examination showed an extreme condition of vascular plethora. The yellow marrow of the shafts of the long bones was transformed into red. This special combination of symptoms had been described by several observers, notably by Osler.

Dr. NORMAN DALTON inquired if any of the other ductless glands in the body were similarly enlarged.

Dr. HERBERT FRENCH remarked that if the disease were due to an excessive activity of the bone-marrow he would have thought that the oxidation of the tissues would have been rendered thereby easier, whereas, on the contrary, cyanosis was one of the most prominent features. This seemed to suggest that the fault lay in the tissues themselves. He thought that experiments upon the comparative tensions of the carbonic acid and oxygen in the expired air in such a case would be valuable.

Dr. LEONARD S. DUDGEON asked if the blood from the small vessels had been examined as well as that from the tissues. He referred to the condition of the bone-marrow in a case of congenital heart-disease, accompanied by cyanosis, which he had examined at the East London Hospital for Children, which was of a red colour.

Dr. W. PASTEUR asked if any thrombosis were present in Dr. Weber's case, as he had met with this condition in two cases of extreme plethora.

Dr. G. RUSSELL referred to a similar case which he had seen where the spleen was considerably enlarged before any cyanosis appeared. He was also struck with the extreme degree of asthenia present.

The PRESIDENT inquired whether the arteries in the retina were enlarged as well as the veins.

Dr. WEBER, in replying, said that the spleen in these cases might also be regarded as a manometer of the capillary circulation. It was possible that the bone-injury had influenced the polycythæmia by exciting the bone-marrow to increased activity and by diminishing the destruction of erythrocytes.

Mr. JONATHAN HUTCHINSON, jun., read notes of a case in which he had performed intra-cranial resection of the second division of the fifth nerve for epileptiform neuralgia. The patient had remained free from pain at the end of a year. The method adopted was that of trephining the temporal fossa, after which the trunk of the superior maxillary division was exposed, and about half an inch resected. (The paper will be published in full at an early date.)

Mr. STANLEY BOYD mentioned the case of a woman, æt. 69, in whom he had performed a somewhat similar operation for intractable neuralgia. In this case some recurrence of the pain took place after the end of a year, though to a much slighter extent.

Dr. W. PASTEUR and Mr. T. H. KELLOCK communicated a case of

FOREIGN BODY IMPACTED IN BRONCHUS; REMOVAL BY OPERATION.

The patient was a boy, æt. 5, who swallowed a glass stopper. Four days later physical signs at the apex of the left lung were discovered by a doctor, and he was sent in to the Middlesex Hospital. On deep respiration a stridulous, wheezing sound could be heard. The temperature was 102·8°. Examination of the chest revealed signs of obstruction in the left bronchus. An X-ray examination showed an indefinite shadow in the region of the left bronchus. Tracheotomy was at once performed, and a foreign body could be felt with a probe passed down the trachea. Attempts to dislodge it with this instrument or with the forceps proved unsuccessful, but the stopper was finally recovered by the aid of a rather stiff loop of wire. The wound in the trachea was closed, after cleaning away some pus which had come up with the foreign body. Four days later the wound had practically healed, and shortly afterwards the physical signs in the chest became normal.

The PRESIDENT referred to a case in which pulmonary symptoms were present resembling those of tuberculosis, insomuch that the patient was sent on a sea-voyage. One day, however, he expectorated a little blood and a piece of a broken tooth, after which the chest trouble, which had persisted for some months, disappeared.

Dr. GEORGE EASTES remarked upon the value of inversion in these cases, especially when the foreign body was almost on the point of coming up, but was sucked back again by inspiration.

Mr. G. H. MAKINS said that glass objects sometimes

threw definite shadows on the screen. He recalled a case of great dyspnœa due to a suspected foreign body in which the cause of death was found to be owing to obstruction from a caseating bronchial gland.

Mr. J. HUTCHINSON, jun., remarked that the glass stopper, though to all appearances clean, was probably virulently septic, hence the formation of pus in the present case. He agreed that the flexible silver-wire loop often succeeded in extracting foreign bodies when all other means had failed.

Dr. PASTEUR and Mr. KELLOCK replied.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

MEETING HELD FRIDAY, MARCH 11TH, 1904, AT THE ROOMS OF THE MEDICAL SOCIETY OF LONDON.

Mr. JOHN BARK, F.R.C.S.Edin., President, in the Chair.

THE PRESIDENT delivered his Presidential Address, which we hope to insert at length in an early number.

Dr. KELSON showed a case of "Paralysis of the Right Vocal Cord," in a man, æt. 50, who had suffered from difficulty in swallowing for one year.

Dr. HAROLD BARWELL showed a case of "Bilateral Abductor Paralysis."

Dr. PETER ABERCROMBIE read notes of a case of "Caseous Rhinitis."

Dr. WYATT WINGRAVE read a report on the pathology of the above case, and remarked that the conditions were perfectly consistent with fatty changes occurring in old pus. Had it originated in epithelial cells there would doubtless have been evidence of squames and cholesterin.

Dr. FRED. SPICER showed a laryngeal case for diagnosis in which there had been a gradual loss of voice, but neither a tuberculous nor a syphilitic history. A tumour was visible in the larynx. There was improvement under iodide of potassium.

Dr. R. H. WOODS advised that tubercle bacilli be carefully examined for, as in a similar case they had been found.

Mr. MAYO COLLIER suggested that the case was one of syphilis, but said he would first examine the sputum for tubercle bacilli.

Dr. DUNDAS GRANT showed a case of "Acute Laryngitis" following influenza.

Mr. MAYO COLLIER showed a case of "Chronic Osteo-myelitis," with old ulceration of the palate, and asked for the opinion of the Fellows on it.

Mr. CHICHELE NOURSE said that there was some haziness of the corneæ, and that he thought it was a case of congenital syphilis.

Mr. KELSON considered that the eyes gave evidence of inherited syphilis, the corneæ being nebulous. Probably the eyes were affected at an early age.

Dr. D. VINRACE said that the teeth also bore evidence of congenital syphilis.

Dr. WOODS showed a skiagram of a maxillary antrum, containing a piece of indiarubber drainage-tube which had been retained after an operation eight years before.

Dr. WOODS showed an artificial denture removed from the gullet of a lady patient, where it had remained for four months. There was now a fistula between the œsophagus and the trachea at the level of the cricoid cartilage. Œsophagotomy was performed for the removal of the denture, but the fistula still remained.

Dr. DUNDAS GRANT suggested that a large tracheal incision would be a good method of reaching the fistula. A case had been reported where success was attained by means of a tracheotomy tube with a jacket of indiarubber, this being maintained in position for one year.

The PRESIDENT said the case was a very interesting one, and that he had never seen a case like it.

Dr. WYATT WINGRAVE showed microscopic specimens illustrating recent histological investigations respecting malignant growths. Two forms of cancer parasites were exhibited—parasites free and encapsuled—which had been found in innocent as well as in malignant tumours.

Dr. G. GEORGE REID exhibited an automatic sounding-box for measuring the auditory appreciation in deafness and other forms of ear disease.

A NEW INVENTION.

A small audiometer for testing the auditory appreciation in deafness and ear disease. Up to the present the method of testing by striking a tuning-fork has been inefficient, and for reference or further testing useless. The important points in this instrument are :—(1) The force starting the fork is constant both for one and for every fork, therefore there is never variation in volume in the same fork. (2) The individual fork is constant for one and the same patient, and for every other patient at any time ; therefore, the record is a valuable reference in a patient's history or for comparison, and as noting the value of any medical or surgical treatment or appliance. (3) The fork is heard by the patient and operator at the same time, and it is heard under the same condition. After some experiments, it has been found advisable to keep the box at this size for either one, two, three, or four forks, considering the question of vibration. For whilst, on the one hand, you do not wish to unduly lengthen the period of vibration, on the other hand you do not want to diminish it too much. The forks can be chosen by the surgeon, the C fork being the usual one supplied. The terminals are of glass, which can be removed after each patient and dropped into an antiseptic solution, and replaced by fresh ones. I may add that the instrument is a valuable assistant to the operator, should he be suffering from temporary deafness due to catarrh, as the volume of the fork never alters, and the normal period of appreciation being known, his subjective condition does not prevent the correct determination of the patient's time of audition. There is no objection to variation in the length of the tubes.

Dr. D. VINRACE asked if it would assist in calculating the percentage of hearing power.

Dr. HEMMINGTON PEGLER wished to know how the over-tones were to be got rid of, and if a range of forks could be used, and remarked that the name "audiometer" was in danger of being confounded with "acometer."

Dr. HASLAM asked how air and bone conduction were to be distinguished.

Dr. DUNDAS GRANT thought this instrument would prove useful in recording the progress of an ear case.

Dr. WOODS asked if it could test bone conduction.

Dr. HAROLD BARWELL thought that the spring would gradually get weakened.

Dr. R. H. WOODS likened the spring to that of a watch, which did not weaken.

Dr. FRED. SPICER considered it full of fallacies—transmitting a mixture of bone and air conduction.

Dr. ST. GEORGE REID, in reply, said that there was no bone conduction whatever in using this audiometer. The spring had not been found to appreciably lessen in strength. Over-tones were not of any importance, as they were constant, being always started with the same force and in the same manner.

Dr. DUNDAS GRANT, in opening the adjourned discussion on Mr. Mayo Collier's paper on "Latent or Intermittent Nasal Obstruction," said that he could not agree that the subject had not been noticed before by rhinologists, as it was discussed at the meeting of the British Medical Association in 1888. The effect of nasal obstruction on the ear was still a disputed point. The part that negative pressure played was still in doubt. Dr. Scanes Spicer's investigations were mentioned. Typical sclerosis of the ear must be placed in a separate chapter as nasal obstruction had no effect in this condition. The hollow groove on the nasal septum was not, in Dr. Dundas Grant's opinion, always produced by the engorged inferior turbinal. The groove was often more apparent than real, a well-developed

Jacobson's cartilage accounting for this in some cases. The treatment he relied on, in many cases, was galvano-cautery puncture. High frequency currents might be useful for intra-nasal vascular dilatation.

Dr. R. H. WOODS said that he doubted the effect of nasal obstruction on ear pressure, as the Eustachian tube was a closed tube except during swallowing.

The discussion is to be continued at the next meeting.

The Annual Dinner was held at the Imperial Restaurant the same evening.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, MARCH 2ND, 1904.

Professor JOHN CHIENE, C.B., President, in the Chair.

MR. H. J. STILES showed (1) patient after operation for epilepsy following suppurative leptomeningitis, the result of middle ear disease. Two years previously the patient had been successfully trephined for meningitis, and for the last nine months had suffered from epilepsy. Adhesions at the old trephine wound were suspected, the skull was again opened, the dura removed, and a piece of gold leaf inserted over the brain; the scalp was then replaced. There was some suppuration, probably from organisms which had remained latent in the old scar tissue, and the gold leaf subsequently came away, but there had been complete freedom from fits since the operation. (2) Infant after ligature of both common carotid arteries for chronic hydrocephalus, an operation which was tried, as all those already in use were unsuccessful. The head had only enlarged a quarter of an inch in circumference since the operation. (3) Two patients, after thoracoplasty for empyema. In the first the fourth to ninth ribs had been resected on account of an empyema of three months' standing, which had burst through the intercostal muscles and become subcutaneous. The interesting point was the deformity of the spine, which showed convexity towards the diseased side, but no rotation of the vertebral bodies. The other patient was shown to contrast with this, the deformity being of the usual type, with the concavity towards the diseased side.

Dr. W. T. RITCHIE showed a man, æt. 41, with intrathoracic pressure symptoms: huskiness of the voice and paralysis of the left vocal cord in the cadaveric position, inequality of the radial pulses, increased width of the left palpebral aperture and dilatation of the pupil. The heart was slightly hypertrophied, the arteries thickened, and there was a history of syphilis, pointing, therefore, to aneurysm.

Dr. CHALMERS WATSON showed a woman suffering from exophthalmic goître of ten years' duration, and her son, æt. 10, born just after the symptoms began, showing general weakness and loss of appetite, enfeeblement of the circulation with coldness of the extremities, tachycardia and von Graefe's sign—all probably referable to alterations in thyroid and parathyroid secretion.

Mr. F. M. CAIRD showed a patient after jejunostomy for cancer of the stomach. Owing to the extent of the disease, gastro-enterostomy had had to be abandoned. By making the opening into the jejunum after Witzel's method, he had obtained a fistula, through which patient could be fed, but through which no intestinal contents escaped.

Dr. BYROM BRAMWELL showed a case of pancreatic infantilism, a new disease, illustrating the benefits of treatment by pancreatic extract. Two years ago the patient was nineteen, and looked like a boy of 11 or 12. There was no arrest of mental development—only retardation of physical growth. The different parts of the body were well proportioned, and there was no evidence of cretinism, congenital syphilis, rickets, or tubercle, to which stunting was often due. The only cause seemed to be chronic diarrhœa of nine years' duration. The genitalia were quite undeveloped; the height was 4 ft. 3¼ in. The diarrhœa was proved to be due to defective pancreatic secretion by (1) the presence of undigested fat in the stools, and its disappearance when pancreatic extract was given; (2) small amount of phosphoric acid in the urine on milk diet, with increase when pancreatic extract was given; (3) the use of Sahli's test capsules of glucoid containing iodoform, which showed that iodine was only eliminated in the saliva when the patient took pancreatic extract. The patient had now been under treatment with pancreatic extract for two years, and had grown five inches, he looked much more like his age, and the genital organs had developed, there being a growth of pubic hair, increase in the penis and testicles, &c.

Dr. JOHN THOMSON showed two cases of infantilism similar to Dr. Bramwell's case. The elder was twenty-four, and was about the size of a boy of 10. He was perfectly intelligent, had none of the signs of cretinism; the genitals were undeveloped, the colour a peculiar yellowish pallor, the voice high pitched, and there had been digestive disturbance and abdominal distension for many years. The patient had had from four to seven motions daily, for which many remedies had been fruitlessly tried. He had grown one and a half inches between 15 and 17½ years, two inches from 17½ to 19½, and since then had remained stationary. Skiagrams showed an ossification of the epiphyses corresponding with that of a child of six or eight years. The second case was æt. 18, and resembled a child of eight or nine. He was quite intelligent, and appeared to be of the same type as the preceding. In him the diarrhœa was periodic, there being six or seven attacks yearly. He had just come under observation. In neither case had pancreatic treatment yet received a trial.

Mr. STILES showed (1) hernial sac of a child containing the vermiform appendix adherent to the testicle; (2) portions of intestine resected for obstruction; (3) congenital displacement of the kidneys, associated with extroversion of the bladder and sacral teratoma; (4) gangrenous Meckel's diverticulum; (5) two renal sarcomata.

Mr. MILES showed (1) portions of resected small intestine from cases of hernia and traumatic rupture; (2) three prostates removed by perineal prostatectomy; (3) portion of rectal mucosa excised for prolapse.

Dr. GIBSON showed skiagrams from a case of infantilism.

Mr. COTTERILL showed specimens from recent operations for appendicitis.

Mr. THOMSON showed stomach from a man, æt. 47, enormously dilated in consequence of pyloric stenosis from ulcer.

Dr. ALEXANDER BRUCE gave a demonstration of electrical currents of high frequency, their mode of production, and therapeutic applications. After explaining what high frequency currents actually were, and demonstrating the condensers from which they were obtained, and the static machines and coils used to excite these condensers as well as the various electrodes, couches, &c., used in their practical application, Dr. Bruce adverted to the unfortunate if not unnatural scepticism with which these and allied methods of treatment were apt to be regarded. He was convinced that in certain directions they had definite value, though, of course, much was claimed for them by their more enthusiastic advocates which they could never fulfil. He proposed to speak only of their benefits from his own experience. He had found them of great service in the relief of pain; in neuralgias, neuritis, locomotor ataxy, rheumatoid arthritis, acute muscular rheumatism, fibrositis, lumbago, and neurasthenic pains generally. The general condition was also improved in these conditions by their use. In hysterical pain they did not seem of service, but rather aggravated the suffering. Neither were they useful in convulsive disorders or diseases accompanied by tremor. They also did good in neurasthenia, and shortened the irksome course of the Weir-Mitchell method of treatment. He thought that he had also got improvement in some of the forms of primary muscular atrophy. They usually produced a feeling of *bien être*, and improved the sleep. He had seen good

effects in dilatation of the stomach due to atony, and in hæmorrhoids. It was extremely doubtful whether they could do any good in gout, diabetes, tubercle, arterio-sclerosis, or cancer.

Dr. BRAMWELL felt that the Society was to be congratulated in that one whose judgment they could so thoroughly trust as Dr. Bruce's had taken up the subject. It would be a great step if they really benefited muscular dystrophies.

Dr. GARDINER spoke of failure in the treatment of tuberculosis with high frequency currents, and

Dr. WEBSTER compared their action on the skin to that of the Nauheim baths.

Mr. DAVID WALLACE read a paper on chronic intestinal obstruction caused by annular stricture (malign) of the large intestine, an abstract of which will be found on page 282.

The subject was discussed by Mr. F. M. Caird, Mr. Stiles, Dr. Affleck, and Mr. Thomson.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

MEDICAL SECTION.

MEETING HELD FRIDAY, MARCH 4TH, 1904.

SIR J. W. MOORE in the Chair.

MILK: HUMAN AND BOVINE.

DR. WALTER SMITH made a communication upon milk, and demonstrated some chemical tests which have been recently proposed. One of the most curious facts in regard to the composition of milk is the presence in it, in measurable amount, of citric acid, which may be considered a specific product of the mammary gland. It has been shown that cow's milk includes from 1 to 3 times as much citric acid as woman's milk, and the amount may be reckoned as equivalent to about 0·25 per cent. of calcium citrate. To distinguish between human and bovine milk a simple test has been advanced by Unikoff, of St. Petersburg. It consists simply in treating the milk with half its volume of ordinary liq. ammonia, and keeping the mixture at a temperature of 60° C. for about twenty minutes. Human milk assumes a violet red colour, the shade being deeper according to the puerperal age of the milk. Cow's milk turns faintly yellow. This test is valid and satisfactory. Mr. Saul has proposed a test to distinguish raw milk from scalded or boiled milk. To 10 c.c. of milk add 1 per cent. of a recently prepared aqueous solution of ortol (used in photography), and then one or two drops of H_2O_2. A vivid deep red colour is produced. Boiled milk is unaffected. To detect formaldehyde added to milk as a preservative, a simple test has been proposed by Manget and Marion. Sprinkle a few crystals of amidol (another photographic developer) on the milk, slightly diluted. Fresh milk quickly assumes a pink or salmon colour. Milk, which contains a very small trace of formaldehyde, slowly assumes a canary yellow colour.

Dr. LANGFORD SYMES laid stress upon the practical importance of Dr. Smith's paper, and strongly endorsed the opinion as to the futility of giving lime to children as a medicinal measure. The only use of lime added to cow's milk was to modify the physical properties of the curd in the stomach. Too little was absorbed from the digestive tract to render lime of use in treating rickets. He believed that it was not fully understood to what extent sterilisation altered the properties of milk, and expressed the opinion that a diet of sterilised milk was capable of producing rickets and scurvy in children. It was open to question whether human milk was secreted absolutely sterile or not.

Dr. TRAVERS SMITH asked if the citric acid in milk was affected by boiling, for if such were the case an explanation was afforded of the powers of sterilised milk to produce scurvy.

Dr. Coleman and Dr. Cranny also spoke.

Dr. WALTER SMITH, in replying, thanked the members for the interest his paper had elicited. He stated that calcium citrate being less soluble in hot than cold milk, some was removed in the scum of boiled milk.

THERAPEUTICAL SOCIETY.

MEETING HELD AT THE APOTHECARIES' HALL, LONDON, TUESDAY, FEBRUARY 23RD, 1904.

DR. ROSE BRADFORD, Vice-President, in the Chair.

DR. J. BURNET, of Edinburgh, read a paper on ichthoform and ichthargan, of which the following is an abstract:—

After briefly referring to ferrichthol and certain of the other compounds of ichthyol, Dr. Burnet went on to speak more particularly of ichthoform and ichthargan. He referred more especially to his use of the former as an intestinal astringent and antiseptic. He found that in tuberculous lesions of the intestinal tract ichthoform gave great satisfaction. Where diarrhœa was a prominent symptom he had frequently administered this ichthyol compound in doses of from ten to fifteen grains thrice daily, with marked effect. He suggested its use as an enema with mucilage of starch. Ichthoform had also given him very good results in cases of varicose ulcer, and also in a variety of skin affections, including eczema. He mentioned ichthoform gauze as a substitute for iodoform gauze for packing cavities. With regard to ichthargan he had found it very beneficial in quite a number of cases of urethritis, and in gynæcological affections he had used it with marked success. In skin diseases ichthargan had been employed pretty extensively with uniformly good effect. In atrophic rhinitis Dr. Burnet found an ointment containing 1 per cent. of ichthargan extremely useful. He referred to its use in diseases of the eye, and mentioned that it might be given internally. He concluded by stating that the various preparations have a wide sphere of therapeutic application.

(In a future issue we hope to give this paper at length.)

A cordial vote of thanks was given to Dr. Burnet for his paper.

MR. W. MCADAM ECCLES read a communication "Respecting Trusses and their Uses," which will be found on page 277 of the present issue.

A vote of thanks was given to Mr. Eccles for his paper.

Special Articles.

BRITISH SANATORIA FOR CONSUMPTION.—XXXVII.

[BY OUR SPECIAL MEDICAL COMMISSIONER.]

MOORCOTE SANATORIUM, EVERSLEY, HANTS.

FOR many cases of phthisis seclusion from all the stress and strain indissolubly connected with residence in or near town or city is an absolute necessity, and when combined with picturesque surroundings, protection from unfavourable climatic conditions and associated with strict medical supervision, the best is provided for the establishment and maintenance of processes making for arrest and restoration. Such therapeutic requirements are amply provided at Moorcote. This sanatorium was established in 1899, and is situated close to the northern border of Hampshire in a district, the natural features of which have marked it out as chief favourite for public institutions of national importance and constituted it a suitable sanatorium country for the metropolis. The landscape is varied and rich in natural beauty, pine trees abound, and everywhere there is evidence of unspoilt rural simplicity. The subsoil is of gravel and speedily dries, even after heavy rain. The roads are excellent for cycling. Beautiful walks abound. And it must not be forgotten that Eversley is rich in associations, for in the quiet, quaint, and isolated rectory Charles Kingsley spent thirty years of his busy life; and here he lies in the sombre little churchyard close to the country he long loved so well.

The main building of the sanatorium consists of a two-storeyed building of good construction with a large hall, airy corridors, and convenient rooms each with casement windows. Here nine patients can be accom-

BEING THE SUPPLEMENT OF THE "MEDICAL PRESS AND CIRCULAR."

MARCH 16, 1904.

NOTICE TO CORRESPONDENTS IN IRELAND.

SUBSCRIBERS to, and correspondents of, THE MEDICAL PRESS AND CIRCULAR who live in Ireland are requested to address their letters, subscriptions, &c., in all cases to the Irish office of the Journal, 16 Lincoln Place, Dublin. If Irish matter is forwarded to the English office delay results, as it has in such cases to be re-forwarded to the office responsible for dealing with it.

CONTENTS.

MR. O'MALLEY'S BILL.

MR. O'MALLEY'S Bill for the superannuation of union medical officers at sixty-five years of age or earlier, if from accident or disease they become unable to carry out the duties of their office, is printed. Thus the initial step has been made in this very necessary reform in the Poor-law Service, and we are glad to see that the Bill is non-contentious. Of course, some crank may come forward and defeat the effort to better the existing conditions of service and postpone an act of justice for years. In its present stage the Bill is open to friendly criticism, and we believe it is the wish of the authors that it be made as perfect as possible without introducing contentious matters; hence, although we find ourselves in accord with the principle of service on which the pension is based, we think that there should be a good service clause, enjoining the addition of a given number of years to those on which the pension is calculated in all cases in which no complaint, other than a trivial one, has been made against the officer during his term of office. If a public servant has completed forty years service, performing his duties so well that no serious charge was brought against him, we think that instead of paying him a pension of forty-sixtieths, he should be paid the fifty-sixtieths of his salary. Such a provision would be a reward to efficient officers without in any way violating the principle of the Bill. We would also like to see introduced into the Bill the pensioning of the wives of officers who met their death in the discharge of their duty. Dr. William Smith's death in the performance of duty does not stand alone. Is not the widow of such a man entitled to a two-thirds salary pension? It is the duty of the State and the people to honour and reward those that its best sons have given to their care. We know that every additional line adds to the difficulty of carrying a Bill through Parliament; but justice and honour demand that the widows and orphans of men whose noble deeds and self-sacrifice called forth the admiration of the nation should be remembered. We honour ourselves by fulfilling such a duty.

THE CORK SANATORIUM.

IN to-day's issue we report, as fully as our columns admit of, the inquiry held on the 1st inst. in the board-room of the Cork Workhouse, into the petition presented by the Cork Rural District Council for a provisional order to provide a sanatorium for consumptives for the City and County of Cork. And also a report of the proceedings on the same date of the Midleton Board of Guardians, in reference to the same sanatorium, when a deputation from the Cork Branch of the National Association for the Prevention of Consumption waited on them. The circumstances that called for the inquiry and brought about the deputation are of such importance, and so far-reaching in their effects, that we think they deserve more than ordinary notice. On December 11th, 1903, a deputation from the Society for the Prevention of Consumption waited on the Cork Rural District Council and solicited them to take advantage of the powers they possessed under the Local Govern-

ment Act (Ireland), of 1902, which legalised contributary payments to infirmaries and so forth; the initial step of which was the formation into a united district of the Urban and Rural Districts of the County and also of the Corporation of the City, for the purpose of providing a sanatorium for consumptives. On the 17th, the Rural District Council passed a resolution asking the I.L.G.B. to sanction the amalgamation so far as was necessary for the contemplated action. This was but the beginning of the arduous task that had been undertaken by the Cork branch of the National Association on the initiative of Dr. P. J. Cremen. But they were so successful in their first move, and so enthusiastic in the cause, that they have carried through their scheme, and Cork will be the richer for their efforts by the first sanatorium sanctioned under the Act in the three kingdoms. This success is the outcome of a well-organised body of enthusiasts in sanitary science who, living in a city decimated by phthisis, had daily before their eyes the necessity for such an institution as a sanatorium. By lectures and letters to the public papers they educated the people to the recognition of the fact that the disease which was so rife in their midst was a curable one, and that the cure was fresh air and proper food, and that to ensure these an hospital of a special construction, and in a healthy locality, was a necessity. To accomplish their self-imposed task the medical members of the Cork branch, assisted by their rural brethren, travelled backwards and forwards through the length and breadth of the county, reasoning and persuading urban and rural councils until they induced the whole twenty boards to become contributing members to 1d. in the £, on the valuation, which is more than sufficient for a building twice the size of that about to be erected, as the county valuation is £1,094,346, and that of the city £172,085, making a total of £1,265,431. The discussion at the Midleton Board of Guardians is interesting as showing the interest that is being taken in the treatment of the disease and as a proof of the care with which the Cork branch had prepared their statistics and facts before engaging in the work. What the Cork physicians have done in this matter should be an incentive to members of the medical profession in other counties to emulate their successes. The difficulties in Cork were many and great. Twenty boards had to be convinced that a sanatorium was not only urgently wanted but that its erection and support would in the end result in a saving. The immense size of the county made a sacrifice of time and comfort unavoidable, and yet the zeal and energy of the Cork men were equal to the task, and they have scored the honour of being the first to secure to the people the great blessing of a sanatorium for the poor, as a right from the ratepayers. We sincerely hope that their example will not be lost on the other county branches of the National Association.

COUNTY CORK SANATORIUM.

ON Tuesday, the 1st inst., an I.L.G. Board inspector held an inquiry in the Board room of the Cork Workhouse, the result of a petition by the Cork Rural District Council, for a Provisional Order to provide a sanatorium for consumptives for the County and City of Cork. The matters which led up to the signing of the petition were that a deputation from the Society for the Prevention of Consumption appeared before the Cork Rural District Council, who on December 17th, 1903, passed a resolution, asking that they be formed into a united district with the several urban and rural districts in the county, and also with the Corporation of the City, for the purpose of providing for the inhabitants of the united districts under the powers of the Public Health Act, an hospital or sanatorium for curable cases of consumption; and that, subject to the consent of the other councils being obtained, the L.G. Board should make a Provisional Order on the subject. Subject to the provision that the cost on the united area should not exceed one penny in the pound a year. The valuation of the County and City of Cork is calculated, on a penny in the £, to yield £5,331 1s. 1d.—a sum fully equal to the support of the proposed sanatorium. Professor Corby said the Corporation of the City of Cork was heartily in support of the scheme, both from a financial and hygienic point of view. Financially, it would benefit by restoring the worker to his employment, and the two years' burden of a workhouse infirmary patient would be avoided, as would the propagation of the disease by the infection of other workers. He warmly recommended segregation of all consumptives, and the foundation of sanatoria for advanced cases as the true and best prophylactic for the disease. It was also necessary for them to clear away the wretched hovels in which some of their poor lived. In recently visiting some of their back streets he found seven people with but 336 cubic feet space in all. Eleven persons were found living in one room. That, was a most scandalous state of affairs. Everything in such surroundings was favourable to the propagation of phthisis. Dr. Ashley Cummins said that in 1903 the number of deaths was 135 from consumption alone. The Cork District Hospital, to which he belonged, was absolutely unsuitable for the treatment of consumption. Not the least of the advantages of a sanatorium would be its educative effect on the patients. Nothing could be worse than the tenement houses, every room of which became, from expectoration on the walls and floors, a nidus of the disease. Dr. Donovan, Superintendent Medical Officer of Health, said the estimated population of Cork City in 1901 was 76,162. The death-rate for 1903 was 19·38; the death-rate from phthisis was 3·66. During the year the mean temperature was 53·61; the mean reading of the barometer was 29·92; and the rainfall 52·77 inches. The prevailing winds were south and west. "The City of Cork possesses the unenviable notoriety of having a higher death-rate from consumption than any other town in Great Britain and Ireland." Dr. Donovan recommended as prophylactic measures the following:—(1) Voluntary or compulsory notification of phthisis; (2) isolation and disinfection; (3) a sanatorium for incipient cases, and isolation hospitals for advanced cases; (4) instruction in elementary hygiene in public and private schools, and specially on the value of air, light, and cleanliness (5) the providing of houses for the very poor; (6) the systematic examination of the milk supplied to the people. Dr. O'Meara, Skibbereen, thought the disease infectious. Dr. Cremen said he thought promiscuous spitting should be prohibited. In the year 1902, there were 985 deaths from phthisis in the City and County of Cork, whilst in the rest of Munster, comprising Clare, Limerick, Tipperary, Kerry and Waterford there was only 1,309. Mr. C. F. McMullen, C.E., said an hospital of forty beds would cost £150 a bed on an average. If they afterwards wanted further accommodation the chalet system could be adopted. A tax of a penny in the £ would support eighty beds. Mr. Barter had generously offered a site of twenty acres at Myshall, Coachford, which, he thought, should be accepted, as the position and grounds were most suitable for a sanatorium. The proceedings then closed with a vote of thanks to the inspector.

Irish Unions.

MIDLETON UNION.

At the meeting of the Midleton Board of Guardians, held on Tuesday, the 16th ult., a deputation of medical men was received by the Guardians. The deputation attended to submit the claims of the Cork branch of the National Association for the Treatment of Consumption. Mr. Rohan, a guardian, opposed the levy of a penny in the £, on the valuation of the Union "for Blarney air." He contended that the sum the guardians consented to give, £375 a year, which with costs of collection amounted to £400 a year, was too much. It practically meant handing over £10,000 to the Cork Association. And he believed the money would be more advantageously spent in building suitable dwellings for the poor. Dr. Cremin, in addressing the Board, said the representatives of the Cork City hospitals and their medical friends in Midleton were one with them on this question. He then proceeded to show the necessity that existed for the proposed sanatorium. Provision had been made for every class of disease except consumption, which was decimating their poor. They had appealed successfully for aid on behalf of the institution to all the urban and rural districts, and the actions of these bodies was a credit to themselves and to Ireland. He reminded the Board that they would get due and proper representation on the governing body of the proposed sanatorium. He showed by statistics that consumption in its early stages was curable, and instanced how much Germany did to check the ravages of the disease, and he stated that even from an economic point of view the expenditure was justified. Dr. Gelston Atkins supported the view put forward by Dr. Cremin. He said the rapidly increasing death-rate from consumption told that the sanatorium was urgently needed. The rate had risen from 40 per 10,000 in 1896 to 230 per 10,000 in 1901. He agreed with Mr. Rohan that the sanatorium of itself was not enough, good houses for the poor were very necessary, but the Association thought it wisest to commence with the sanatorium. In Germany they had seventy sanatoria, and in England and Scotland, since the introduction of sanatoria, the death-rate was considerably less. He also mentioned that there were 239 deaths from consumption in the County and City of Cork during the ten years 1892-1901, and he quoted statistics to show that the loss represented a sum equivalent to £345,000, which shows the desperate loss this disease is from an economic point of view. Mr. Riordan, in a short and excellent speech, appealed to Mr. Rohan to withdraw his motion and allow the grant to be passed unanimously, which Mr. Rohan did, and the deputation, having thanked the Board, withdrew.

On Friday, the 4th instant, an I.L.G. Board inspector held an inquiry in the board room of the workhouse, into the circumstances under which Mary Cashman met her death. Dr. O'Connel, dispensary doctor of the Castlemartyr district, requisitioned by certificate the relieving officer for the infirmary ambulance to remove two women, Mary Barry and Mary Cashman, the latter of whom died two hours after her admission to the house. From the evidence, it appears that Dr. O'Connel filled and left his medical certificates for the removal of the patients and the requisition for the ambulance at Castlemartyr dispensary station, and that verbal messages only were given to Fitz Mahoney, the relieving officer at Midleton, by the friends of the patients. The relieving officer declined to act on their message, or to take any steps in the matter until he had the medical certificate, on the ground that "the medical officer in charge of patients was bound to send the certificates to him, either by post or by the patient's friends." The friends seeing that they could not get the ambulance, had the two patients conveyed to Midleton by train and a common springless country farm cart. The decision is awaited with much interest. We think that commonsense might have suggested to the relieving officer that a telegram to Dr. O'Connel telling him of the fact would have secured the ambulance, and have made unnecessary the sworn inquiry and its expense, and the ill-feeling that it so often engenders.

CAVAN UNION.

At the meeting of the Cavan Board of Guardians, held on Tuesday, the 1st inst., a letter was read from the I.L.G. Board relative to the charges made against Mrs. Duff, midwife of the Ballinagh dispensary district, and the Board have decided with reference to the Guardians' views on the matter, that they will not press for Mrs. Duff's resignation. They, however, think that the Guardians should severely censure her, and inform her that the facts have been noted against her in the records of the department. The attention of the medical officer should also be formally drawn to Article 16, par. xviii., of the dispensary rules under which he is required to report to the Board of Guardians, or to the I.L.G. Board, any neglect or failure on the part of the midwife to discharge punctually and properly the duties appertaining to her office.

IRVINESTOWN UNION.

At the meeting of the Irvinestown Board of Guardians, held on Wednesday, the 2nd inst., Dr. Warnock, of Trillick, was appointed medical substitute for Irvinestown Workhouse and dispensary district, during the illness of Dr. Graham, at a salary of £6 6s. a week. An amendment, fixing the remuneration at £4 4s. a week, found no supporters. We think that such an object lesson ought to tell the I.L.G. Board that the Guardians in every part of Ireland have come to fully recognise that the union medical officers throughout the country are worthy of a rate of payment much higher than the central authorities are willing to sanction.

TULLAMORE UNION.

At the weekly meeting of the Tullamore Board of Guardians, held on Tuesday, the 1st inst., a letter was read from Dr. W. J. McCarthy stating that he would go to reside at the Blueball residence "within a few weeks," that is provided the necessary repairs were executed in the meantime. The Guardians declined to consider the notice of motion as Dr. McCarthy was not residing in the Blueball residence and had not signed the agreement. They said they could not leave the poor of the district any longer without a resident doctor, and ordered the clerk to inform Dr. McCarthy, that if he were not residing in Blueball, and had not the agreement signed before their next meeting they would take steps to elect his successor.

KILRUSH UNION.

At the meeting of the Kilrush Board of Guardians held on Saturday, the 27th ult., a letter was read from the I.L.G.B. drawing attention to the condition of the workhouse and the workhouse infirmary. The report to the I.L.G.B., from their inspector, draws attention to the want of accommodation for phthisical patients in the infirmary. There consumptives are inmates of a general ward, and it is recommended that two special wards, one for males and one for females, for the disease be constructed. The male and female probationary yards are described as being "in a disgraceful, state of filth and neglect, the privies being entirely broken

down, and the roofing of the same gone. . . . Wet comes through the ceiling of the hospital, and also into a room used as a sewing-room, which lies between the top wards of the male and female sides. The roofing in the sheds belonging to Ballyena Hospital is also defective in several places, the damp coming into all the wards, but especially into the ward used as a sleeping apartment by the wardsmaids." After some discussion the guardians decided to carry out the suggestions made, and an order was made to refer the question of hospital repairs to the engineer for a report; and an advertisement was ordered to be inserted in the papers calling for an estimate from contractors for the necessary repairs.

STROKESTOWN UNION.

At the meeting of the Strokestown Board of Guardians, held on Friday, the 11th instant, a letter was read from the I.L.G. Board enclosing a copy of their inspector's report on the condition of the house. The report draws attention to the absence of suitable accommodation for consumptives; the necessity for whitewashing the hospital wards; the imperfect condition of the lavatory; the necessity for three new baths for adults and one for children; the faulty arrangements for drying the linen; the fact that the bed-linen, at the time of the visit, was dirty; the deficient water supply; the necessity for a new kitchen range; the neglect in not providing nursing during the night to the infirm female department; and the quality of the brandy supplied. It costs but 3s. 1d. a quart.

GALWAY UNION.

At the meeting of the Galway Board of Guardians held on Wednesday, the 9th instant, a letter was read from the I.L.G. Board, ordering that a new election be held for the appointment of medical officer for the No. 1 Galway dispensary district, as at the last election neither candidate got a majority of votes.

Correspondence.

THE NORTH DUBLIN UNION.

To the Editor of The Medical Press and Circular.

Sir,—My attention has been drawn to a letter in your issue of February 17th, from Mrs. Power, P.L.G.

In that communication reference has been made to the case of a girl who, some twelve months ago, had been under treatment in the North Dublin Union Hospital, suffering from purulent ophthalmia. She was under the care of Dr. Montgomery, and was, by his advice, discharged cured. She left the hospital perfectly well. Although I never had the girl under my care, your correspondent stated in the board Room, at a meeting of the Guardians, that the girl lost the sight of one of her eyes through not being properly treated by me. I was not present at the meeting, but I wrote to the clerk on the next Board day, and pointed out that I never had this girl as a patient, and that she was perfectly well of the disease from which she had been suffering, and I enclosed a report to that effect from Dr. Montgomery. Even then Mrs. Power was not satisfied. She made further statements, but the Board of Guardians marked their disapproval, by passing the following resolution :—

"That the Board have every confidence in the way Dr. Powell treats the patients under his care, and the members deem it inadvisable to interfere with him in his discretion as to the discharge of patients from hospital or otherwise."

Mrs. Power then went behind the backs of her colleagues to the Local Government Board, but the latter, having the full reports of the case, paid no attention to her. I may add, sir, that so long as three-fourths of a Board of sixty-two members endorse my actions in connection with the Union Hospital, I fail to see the necessity of requesting the Local Government Board to intervene.

I am, Sir, yours truly,

Caleb J. Powell, F.R.C.S.I.

30, Harcourt Street, Dublin, February 29th, 1904.

Obituary.

DR. ST. GEORGE ASH.

We regret to announce the death of Dr. St. George Ash, medical officer of the No. 2 South City dispensary district, and physician to Cork Street Fever Hospital. Dr. Ash obtained the licences of the College of Physicians and Surgeons in 1882, and soon after he was appointed to the No. 2 South City dispensary, to the duties of which he devoted himself with unremitting energy. A quiet, unobtrusive, painstaking man, who made the poor of his district his care, and daily, in the wretched slums of the Castle Street neighbourhood, he was found fighting fever in its natural home of dirt and poverty. His name is held in respect and affection among the poor in whose midst he laboured.

DR. M. J. HYNES.

We regret to announce the death of Dr. M. J. Hynes, at his residence, Ray View, Leenane, on Saturday, the 13th ult. Dr. Hynes obtained the licence of the R.C.S.I. and of the R.C.P.I. in 1899. Soon afterwards he was appointed medical officer to the Clonbur No. 2 and the Bundunagh dispensary districts. He quickly became very popular, as was evidenced by the immense numbers that followed his funeral for a distance of thirty miles. His death is ascribed to an attack of pneumonia, contracted at the funeral of his uncle, Dr. Lydon.

ACHILL ISLAND.

An outbreak of small-pox has occurred on Achill Island in two of the largest and most congested villages on the seaboard—Keel and Dovagh. The outbreak is ascribed to a case of the disease which came from Glasgow. The sanitary conditions under which the islanders live are of the lowest type, and in such surroundings, amidst a population a large percentage of which is unvaccinated, the epidemic cannot easily be controlled. Measures for preventing the spread of the disease are being taken. An isolation hospital has been opened by the District Council, under the superintendence of Dr. Croly, the dispensary medical officer of the island, and the services of trained nurses have been obtained.

COUNTY GALWAY HOSPITAL.

At the usual monthly meeting of the Board of Management of the County Galway Hospital, held on Saturday, the 5th instant, Mr. Higgins proposed the following resolution :—"That we, the Board of Management of the County Galway Hospital, request the Local Government Board to hold a sworn inquiry into the circumstances of the refusal of admittance of a man named John Holland into the County Hospital, who since died, and for which refusal of admission this Board does not hold itself responsible." Mr. Murphy seconded the resolution, which was carried unanimously.
